
ALLOXANTIN contains only two molecules of water of crystallisation, which can be completely expelled at 107°–110° and not three molecules as is stated in Beilstein's *Handbueh* (2nd Ed.).

The author also directs attention to the following reaction of alloxantin:—1–2 mgrm. of the powdered crystals are wetted with a drop of nitric acid (sp. gr. 1.4) and carefully heated in a watch glass to expel the excess of acid. On adding a drop of ammonia, and a little water, a beautiful permanent purple coloration is produced, which disappears on drying but reappears on again adding water. Less than 1 mgrm. of the substance can be recognised in this way.

—J. S.

Acids contained in Vegetables, Detection and Separation of the Principal. L. Lindet. *Comptes rend.* 122, 1135–1137.

TARTARIC acid is readily isolated on account of the insolubility of its potassium salt in a mixture of alcohol and ether, but the other acids occurring in vegetables, notably malic and citric, are troublesome to detect and separate. The author finds that the quinine salt serves to separate citric acid, and the cinchonine salt similarly serves for malic acid on account of the sparing solubility of the acid salts in methyl alcohol. The bases are added gradually, in powder, to avoid formation of the normal salts. The cinchonine can be added after the quinine, excess of the latter not interfering with the reaction. The acid can be liberated from the quinine (or cinchonine) salt by adding ammonia, filtering, precipitating with subacetate of lead, and decomposing with sulphuretted hydrogen.—V. C.

Linseed Oil, Linseed Oil Varnish, and Oil Colours; Simple Method of Testing. R. Hefelmann and P. Mann. *Pharm. Central H. N.F.* 1895, 16, 685.

THE authors have found that the presence of resin oil can be more easily detected in linseed oil and linseed oil varnish by means of the butter refractometer than by other methods. Even small additions of resin, resin oil, the salts of the metallic oxides with resin oil acids, and mineral oil, can be detected by the increase in refraction, as is shown by analyses furnished by the authors.—J. S.

Varnishes, Notes on the Drying of. L. E. Audés. *Chem. Zeit.* 1896, 20, 307.

See under XIII. B., page 461.

ORGANIC CHEMISTRY.—QUANTITATIVE.

Paraffin, Pine Resin in, Detection and Determination of. J. Klimont. *Chem. Rev. ä. d. Fett- u. Harz-Ind.* 1896, [38], 76–77.

ONE method is to heat about 10 grms. of substance with some 50 c.c. of 10 per cent. alcoholic potassium hydroxide

to boiling on the water-bath, then add an excess of water and shake up with ether. The paraffin is obtained by evaporating the ether, and the resin by decomposing the aqueous solution by means of sulphuric acid. The estimation of the paraffin may be better effected by evaporating off the alcohol after the treatment with potassium hydroxide and extracting an aliquot part of the residue with ether in a Soxhlet tube.

A rapid and approximate estimation may be made by determining the acid number of the substance. For Austrian resin this averages about 170, and, as paraffin is neutral, the percentage of the former may be determined by the formula—

$$x = \frac{100s}{170m}$$

wherein m represents the quantity used for the titration, and s , the acid number of the mixture. By this method 13.72 per cent. of resin was found in a trial mixture containing 14.42 per cent.—C. S.

Indigo, Valuation of. Chr. Rawson. *J. Soc. Dyers and Col.* 1896, 12, 82–86.

THE author remarks on the discrepancies noticed in the determination of indigotin and indirubin in samples of indigo taken at various times from the same stock. These are due to the hygroscopic nature of indigo. A "table showing the variations in weight of samples of indigo under different atmospheric conditions as regards temperature and humidity," is given in the paper. The author recommends that dealers and buyers should insist upon having the water determined at the same time as the colouring matter, which should be calculated on the *dry indigo* and stated, in addition to that present in sample *as received*.

In the discussion following the paper, J. Grossmann stated that he found that a sample of indigo lost water in grinding.

A. G. Green pointed out that almost all colouring matter had the power of absorbing 5–10 per cent. of water without apparently becoming moist, and it was due to this fact that so many disputes arose about the variations in strength of the colour on keeping, or during long voyages.

In reply, Chr. Rawson said that he had used the permanganate and thio-sulphate (gravimetric) methods for the purpose of estimating indigotin and indirubin in the analyses given in the paper. Potash salts might have something to do with the absorption of moisture by the indigo, but pure indigo itself was hygroscopic.—H. J.

Oils, Oxidation of: Researches on the Determination of the Degree of. M. W. Bishop. *Monit. Scient.* 1896, 259–264.

THE experiments of Chevreul on the influence of metallic surfaces in promoting the oxidation of oils were first extended and made the basis of a quantitative method by Livahe (this *Journal*, 1883, 349), whose process consists in spotting 0.5 grm. of the oil on to the surface of 1 grm. of dry finely divided metallic lead (precipitated from a solution of lead by means of zinc) contained in a watch glass, and observing the increase of weight. But the absorption of oxygen, even in the case of linseed oil, requires from two to five days to reach the maximum, the less strongly drying oils, such as poppy-seed and nut oil, require at least as long, whilst the feebly drying oils must be left for fully seven days before any useful result can be obtained; and even then, as Livahe has more recently shown, the final result is far from representing the maximum absorption. In fact, if we divide the iodine value and the oxygen absorption respectively, of linseed oil by the corresponding values of other oils, the two series of ratios show such a want of accordance as to throw doubt upon the completeness of the oxidation even in the case of nut and poppy-seed oils.

In the case of linseed oil the maximum absorption is obtained, for this oil oxidises rapidly, without the help of any drier, if sufficiently sub-divided by means of a neutral body. Thus, 1 grm. of linseed oil, intimately mixed with

1 gram. of precipitated ignited silica, and exposed in a thin layer to the air at 20–25° absorbed—

	Oxygen per Cent.
In 1 day	0.89
In 2 days	7.31
In 3 days	15.00
In 4 days	16.49

This result suggested the following general method, in which silica is used as the absorbent, and resinates of manganese as the drier.

The Method.—Purified manganese resinate is prepared by digesting the commercial article in ether, filtering, distilling off the solvent, and powdering the dry residue. 5–10 grms. of the oil are weighed in a beaker, 2 per cent. of the dry resinate is added, the oil is heated on the water oven, with occasional agitation, until solution is complete (which takes from 5 to 10 minutes), and is then allowed to cool.

1 gram. of precipitated ignited silica is weighed into a flat bottom capsule of 5.5 cm. diameter, containing a small glass rod, and as nearly as possible 1.02 gram. (1 gram. oil + 0.02 gram. resinate) is distributed from a fine pipette in small drops all over the surface. The whole is then weighed. The oil and silica are next intimately mixed by means of the glass rod, spreading the mixture in a layer of uniform thickness all over the bottom of the dish, and the dish is then exposed to the air at 17°–25° for drying oils, and at 20°–30° for other oils, and weighed at intervals of six hours. After each weighing the contents are stirred afresh.

With linseed oil, the maximum oxidation occurs in from 24 to 30 hours, after which there is a gradual loss of weight, confirming Cloez, Mulder, and others, that, besides linolein, volatile products are formed. By adding 4 per cent. instead of 2 per cent. of the resinate, oxidation is more rapid, but the increase of weight is less, owing to an increased proportion of volatile products. The influence of temperature is most important. The results obtained appear to show that for the most rapid oxidation of linseed oil the temperature should not fall below 17° nor rise above 28°. With the oils of hemp seed, poppy seed, nut and cotton seed, the maximum increase of weight was reached in from 24 to 18 hours at 28°–22°. Sesame oil at the same temperature required 72–96 hours. Arachis oil absorbed 6.7 per cent. of oxygen in 96 hours, at a temperature fluctuating between 32°–18°–34°–11°; but another sample, tested at 23°–17°, only absorbed 4.8 per cent. in 144 hours.

The oxidation of colza, and especially of olive oil, cannot be easily effected in a short time. Thus, with colza oil, although a marked increase of weight is perceptible in 24 hours, which steadily augments, the results recorded show that at the end of 11 days it had not passed the maximum. With olive oil, an increase of weight is perceptible in 24 hours; but one sample took 16 days at 31°–11° to increase 5.3 per cent., and two other samples absorbed, respectively, 5.7 per cent. in 36 days at 34°–18° and 6.0 per cent. in 50 days at 23°–17°. Results obtained and tabulated, show that the adulteration of olive oil with oils of more strongly drying character causes the most marked effect in the first 24 hours, provided the experiment be made at a suitable temperature.

A summary of the author's results is given in the table.

Description of Oil.	Specific Gravity.	Oxygen Absorption.	Mean Value.	Ratio.
Linseed oil (indigenous) ...	0.9327	17.79 to 16.40	17.05	..
" " (La Plata)	0.9304	15.45 to 15.00	15.20	1.12
Hempseed oil	0.9287	11.55 to 11.30	11.40	1.18
Poppy-seed oil (indigenous) ...	0.924	11.50 to 13.30	11.20	1.20
Nut oil (commercial)		13.70	13.70	1.25

Wax, Analysis by Cold Saponification. R. Henriques. *Zeits. angew. Chem.* 1896 [8], 221.

In a former paper (this Journal, 1896, 299) it was shown that all fats and fatty oils can be completely saponified by treating their solutions in petroleum spirit with alcoholic caustic soda in the cold. The alcoholic standard solution of soda should be prepared with alcohol of not less than 96 per cent. strength. This method of saponification may be employed for the analysis of beeswax, in the following manner:—3 grms. of wax are dissolved in 25 c.c. of warm petroleum spirit, and this solution is titrated with half-normal solution of alcoholic soda, using phenolphthalein as indicator. This titration being completed, 25 c.c. of the half-normal solution of alcoholic soda are added, and the mixture allowed to stand for 24 hours, when the remaining free alkali is titrated back in the usual manner. Thus, the following results were obtained:—

Description.	Acid Number.	Ester Number.	Total Saponification.	Huldt's Ratio.
Yellow beeswax R.	29.6	76.5 76.0 76.8	97.1 96.6 97.4	3.72
" " I.I.	29.4	73.9 72.9	94.3 95.3	3.85
" " L.II.	29.6	73.6 75.1	94.2 95.7	3.76
White beeswax R.	22.4	76.1 76.5 76.9	98.5 98.9 99.3	3.41
" " L.	28.4	76.6 77.1	105.0 105.5	2.71

These figures leave no doubt that the cold saponification process is very well adapted for the analysis of beeswax. The advantages of the new method become even more apparent in its application to adulterated beeswax, mixtures of beeswax with ceresin or paraffin wax which offer exceptional resistance to saponification by the ordinary process. By this cold process such mixtures are as readily saponified as the pure article, owing to the complete solubility of the above-named adulterants in petroleum spirit. In its application to the analysis of Carnauba wax, Japan wax, and spermaceti, the new method yields equally satisfactory results. Another class of bodies said to be saponifiable with great difficulty, *viz.*, seal and fish oils, are also readily saponified by this process, which, however, *failed altogether in its application to wool fats.*—C. O. W.

Liquid Fats, The Saponification and Saponification Number of. D. Holde. *Mitt. aus der k. k. tech. Versuchsanst. zu Berlin*, 1896, 14, [1], 82–86.

In proposing his method of cold saponification (this Journal, 15, 299), Henriques asserted that in the ordinary method of saponification there were certain sources of error which often rendered the results inaccurate and variable, especially in the case of castor and cod-liver oils. The author now replies to this criticism after a comparative examination of the two processes. He shows that when the determinations are made on the same day, the figures obtained, either by cold saponification or by heating for 15 minutes or for an hour (with or without the aid of a reflux condenser), are concordant to within 1 unit of the saponification number. Out of 35 duplicate estimations, the difference only exceeded that amount in five cases, the maximum being 3 units = 1.5 per cent. of the saponification number. When the determinations were made at different times (*e.g.*, after intervals of several weeks) the figures obtained, with the exception of four, referring to isolated cases, showed as the highest deviation in 70 experiments, 1 per cent. of the saponification number in the case of castor and cod-liver oils, and 1.5 per cent. with fish oil (dark coloured soap solution). It is suggested that the somewhat greater differences obtained when the saponification is made on different days may be attributed to the varying amounts of carbonic acid in the soda solutions employed. The author's general conclusion is that the mean results of all the modifications of warm saponification agree so well among themselves and with those of cold

saponification, that Henriques' objections are groundless; and that when a speedy result is required, perfectly accurate figures may be obtained in the case of fluid fats (including castor and cod liver oils) by the ordinary methods of warm saponification. At the same time he considers the process of cold saponification a valuable and trustworthy modification.—C. A. M.

Basic Lead Acetate, Behaviour of, towards Sugar Solutions.
H. Svoboda. Zeits. d. Ver. Rübenzucker Ind. 1896, 46, 481.

It is known that basic lead acetate, on account of its basic properties, decomposes solutions of sugar. The author found that when 20 per cent. solutions of the under-mentioned sugars were mixed with one volume of basic lead acetate and allowed to stand 24 hours, they underwent the following alterations in colour:—maltose, rose; galactose, orange; levulose, yellow; dextrose, bright yellow; and milk sugar, golden. The solutions exhibited, moreover, a decrease in opticity, which was least in the case of maltose, and most in that of galactose (53 per cent.). Solutions of cane-sugar and raffinose underwent no change; they remained colourless, and, after slight acidification, possessed their original specific rotation. Raffinose is precipitated from its aqueous solution by highly basic lead acetate. Since the action of lead acetate is dependent on its basicity, that is, on the amount of lead oxide dissolved in neutral lead acetate, it is necessary to titrate, and estimate its activity according to known methods. With regard to the alteration of specific rotatory power in aqueous sugar solutions, the author states that increasing quantities of basic lead acetate at first produce with cane-sugar a slight reduction, then an increase, and finally a diminution; with dextrose a small reduction followed by an increase; with maltose a moderate, with raffinose, milk-sugar, galactose, and levulose a very marked lowering which is proportional to the amount of basic lead acetate added. When lead acetate, slightly acidified with acetic acid, is added to sugar solutions, irregularities in rotatory power are observed. These divergencies are ascribed to the formation of soluble lead saccharates possessing a rotatory power different from that of the sugar. From solutions containing salts, which latter lead to the formation of difficultly soluble lead compounds, basic lead acetate precipitates sugar. That in sugar solutions containing sulphates, chlorides, &c., insoluble saccharates are formed, is probably due to the fact that basic lead acetate forms various saccharates with difficulty soluble in water, but readily soluble in a solution of lead acetate. Basic lead acetate does not usually precipitate sugar, on account of its content of neutral lead acetate, but when the solvent for the difficultly soluble lead saccharate is removed or diminished in quantity, it does. This takes place when the salts contained in the sugar solution react with the neutral lead acetate so as to form insoluble lead salt, and an alkaline acetate.—J. L. B.

Sugars in Fruit Essences, Syrups, Liqueurs, Preserves, and Honey, Estimation of. De Raczkowski. Monit. Scient. 1896, 19—28.

FULL details are given in this paper of the usual modes of analysis by means of the polariscope, and for the calculation of results. The changes in rotation of saccharose (cane-sugar) and of dextrose (glucose) are so small within moderate ranges of temperature that they may be neglected. For invert sugar and levulose correction is necessary. When the concentration does not exceed 14 per cent., the correction for temperature may be found by the formula:—Invert sugar $[\alpha] = -27.9^\circ + 0.33 t$; levulose $[\alpha] = -101.22^\circ + 0.56 t$, where t = degrees C. above 0° C. The ordinary chemical tests are recommended for the detection of tartaric acid, gelatin, dextrin, &c.

—L. T. T.

Fusel Oil, Quantitative Determination of, in Alcohol.
M. G. Kutscherow. Chem. Zeit. Rep., 19, 2082.

THE alcohol is mixed with a saturated solution of common salt and to it is then added a small quantity of amyllic alcohol, equal in amount to about 4 per cent. of the alcohol

being dealt with. An oily layer separates, and is transferred to a graduated tube for measurement. When the volume of the oily layer, which separates out when absolutely pure alcohol is treated in precisely the same way, is known, the difference between the two is an index of the fusel oil present in the alcohol, and is calculated into fusel oil according to a given table.

The method is the same in principle as that of Rose, in which chloroform takes the place of amyllic alcohol. Two modifications of the process are given, one for use in works, with an accuracy of 0.1 per cent. for every per cent. of fusel oil present, and the other for the laboratory yielding results to within 0.017 per cent.—J. G. W.

Hops, The Tannin of. J. Heron. J. Fed. Inst. Brewing, 1896, 2, 162—185.

Estimation of Tannin in Hops.—For this purpose the author recommends Löwenthal's process (Zeits. anal. Chem. 16, 33—48), to which he has added some improvements. 10 grms. of the hops are introduced into a flask graduated to 1005 c.c., 900 c.c. of boiling distilled water are added, and the contents well shaken. The flask is then placed in a bath of boiling water and digested for one hour; it is cooled to 60° F., made up with water to 1,005 c.c., the flask and contents are well shaken, and the extract filtered. The liquid is made up to 1005 c.c. instead of 1000 c.c. in order to correct for the volume occupied by 10 grms. of hops. The author considers that this procedure gives more correct results, since, by the continued successive boiling of Löwenthal's method, a portion of the soluble tannin becomes converted into more or less insoluble phlobaphen, which behaves differently to the tannin, with the permanganate.

For the determination of the tannin in the hop extract the following solutions are required:—1. Permanganate of potassium, prepared by dissolving 1 gm. of the pure salt in a litre of water. 2. Indigo solution: 5 grms. of pure indigo carmine are dissolved in 500 c.c. of water, 50 c.c. of concentrated sulphuric acid added, and the liquid diluted with water to a litre; 20 c.c. of this solution should require 20 c.c. of permanganate. 3. Gelatin solution: 25 grms. of Nelson's gelatin are soaked in 250 c.c. of water for six hours, heated on the water-bath until the gelatin is dissolved, then saturated with sodium chloride and made up to a litre with a saturated solution of the same, well shaken, allowed to stand for a few days, and filtered bright. 4. A solution of dilute sulphuric acid consisting of 50 grms. of concentrated acid in a litre of water. For the determination, 50 c.c. of the hop extract are introduced into a shallow white porcelain basin of 1 litre capacity, 20 c.c. of indigo solution are added, and 500 c.c. of water; the permanganate is run in whilst the liquid in the basin is vigorously stirred; towards the end of the reaction the blue colour produced by the indigo changes first into a light yellowish-green and finally into a golden-yellow. When this point is reached, and a faint pinkish tinge round the edge of the basin is observed, the titration is finished. Two such determinations should be made, and from the mean of them the number of c.c. of permanganate required by the 10 c.c. of indigo solution are subtracted; the remainder, multiplied by 2, represents the total oxidisable bodies in 100 c.c. of the extract.

100 c.c. of the hop extract are poured into a wide-mouthed 16-oz. flask, 100 c.c. of gelatin solution are added, the mixture shaken, and 50 c.c. of the dilute sulphuric acid run in, the flask again shaken, and a teaspoonful of kaolin added, and, after thorough shaking, the contents of the flask are filtered. 100 c.c. of this filtrate, together with the indigo solution and water, are titrated as before with permanganate; the mean of two experiments, less the amount of permanganate required for the indigo, multiplied by 2.5, represents the amount of oxidisable substance in 100 c.c. of the extract after the tannin has been removed; therefore the difference between the former and latter titrations will equal the number of c.c. of permanganate required to oxidise the tannin in 100 c.c. of extract. The author considers it advisable to express the number of c.c. of permanganate required to oxidise the tannin in terms of oxalic acid, since tannins derived from different sources vary

considerably in their properties and give different values when acted on with permanganate. Since, however, the amount of permanganate can be measured by means of oxalic acid, the results by this method are comparable for each individual tannin-containing substance. If a and b represent the number of c.c. of permanganate used in the first and second titrations, c the quantity of permanganate required to oxidise 10 c.c. of $\frac{N}{10}$ oxalic acid, and 10 grms. of hops have been used in making 1000 c.c. of extract, then $\frac{a-b}{c} \times 6.3 = x$, where x is the percentage of tannin expressed in terms of oxalic acid. A correction is sometimes necessary for a slight reducing action of the gelatin solution towards the permanganate.

In order to see what alterations occurred in the tannin when the hops were kept, the author made analyses of the same samples four and eight years after the first analysis, and from the results it appears that the tannin is diminished to a certain extent in kept hops, and probably is first oxidised to the insoluble phlobaphen and thence passes, through a form somewhat allied to gallic acid, into lower derivatives, which are not acted on by permanganate.

Influence of Hop Tannin on Wort.—The author considers that the tannin of hops does not precipitate albuminoid matter from the malt wort in the copper; but there is evidence that it unites and forms a definite compound (tanno-peptone) with certain nitrogenous matters derived from the malt. As this is soluble in the wort, its presence is accounted for in the finished beer. The author concludes that the hop tannin is of no value in the copper, but is a valuable index of other constituents; for hops which have a good percentage of tannin possess *pro rata* resins and bitter substances; hence the determination of the amount of tannin is an indication of the brewing value of any sample of hops.—J. L. B.

Beer Wort, Products of the Fermentation of. A. Straub. *Forschungsber.*, No. 2, 382.

The total acid produced, calculated as lactic acid, increases with the temperature at which the fermentation is conducted, irrespective of the presence or absence of air. Fermentation in the presence of air produces a very much greater proportion of volatile acids than does fermentation in the absence of air. The formation of glycerin decreases with a rise of temperature and with the increase in the total acidity. Between the maltose present and the glycerin formed, no relationship exists. The formation of succinic acid is in no way dependent on the production of glycerin, nor on the maltose present, this being a further proof that Pasteur's theory of the ratio of formation of glycerin and succinic acid can no longer be maintained.

To obtain satisfactory results in the estimation of succinic acid the dextrin present must be removed by conversion with sulphuric acid. The resulting solution is evaporated down to one-third of its volume, neutralised with barium carbonate and then made slightly alkaline with soda. The whole is then evaporated to a thick syrup, 1 per cent. nitric acid added to strong acid reaction, and the whole extracted with alcohol. The alcoholic extract is evaporated down, one and a half times its volume of ether added, and the ether extract filtered off at the end of an hour, evaporated down and the residue taken up with water. In the aqueous extract the succinic acid is estimated as the silver salt, according to Ran's method. The author found in this way from 0.00264 to 0.00392 per cent. of succinic acid in beer.—J. G. W.

Morphine, Estimation of, in Opium. G. Loeff. *Apoth. Zeit.* 1896, 11, 192.

The author has found that sodium salicylate removes those substances which prevent the precipitation of morphine in opium products, and on this fact bases the following process:—5 grms. of the finely powdered opium are triturated with water, and the mixture is made up to a total weight of 44 grms. in a tared flask, which is then closed and well shaken for 15 minutes. 1 gm. of sodium salicylate is added, the shaking repeated for a few minutes, and the liquid filtered. 25.8 grms. (=3 grms. opium) of the filtrate are well shaken for 10 minutes with

3 grms. of ether and 1 gm. of ammonia solution, and the separated morphine collected on a small filter, washed with water, dried, washed with benzene, again dried, and weighed.—C. A. M.

Cinchona Bark, Estimation of the Total Alkaloids in. C. C. Keller. *Schweiz. Wochenschr. Chem. Pharm.* 1895, 33, 149.

The author recommends the following method, which can be completed in a few hours, and which furnishes the alkaloids in as pure a condition as they can be obtained in by any other process:—12 grms. of finely powdered dry cinchona bark, contained in a dry flask of 200 c.c. capacity, are digested with 90 grms. of ether and 30 grms. of chloroform, and frequently agitated during five minutes. 10 c.c. of 10 per cent. ammonia are then added, and the mixture is well shaken. The shaking is continued at intervals for half an hour, when 10 c.c. of water (12–15 c.c. in the case of calisaya barks) are added, and the shaking continued until the liquid has become clear. 100 grms. of the chloroform-ether extract, after standing for 1–2 hours to allow of the separation of water and powdered bark, are carefully poured into a separating funnel and extracted with 30, 20, and then 10 c.c. of 1 per cent. hydrochloric acid. The acid solution is then collected in a separating funnel, made strongly alkaline with ammonia, and again extracted three times with a mixture containing in all 10 grms. of chloroform and 90 grms. of ether. After filtering the solution of the alkaloids into a tared flask through a small filter wetted with ether, the chloroform and ether are distilled off, and the residue dried at 80°–90° and weighed. The weight of the residue corresponds to 10 grms. of cinchona bark.—J. S.

Cacao Leaves, Estimation of the Alkaloids in. C. C. Keller. *Schweiz. Wochenschr. Chem. Pharm.* 1895, 33, 153.

12 grms. of the powdered cacao leaves are treated in a 250-c.c. flask with 120 grms. of ether. After 15 minutes 10 c.c. of 10 per cent. ammonia are added, and the mixture well shaken. Precipitation is effected half an hour later by the addition of 20 c.c. of water and continued violent agitation. 100 grms. of the dark green ethereal solution are then poured off, and, after standing some time to clarify, extracted with 50 c.c. and afterwards with 25 c.c. of 0.5 per cent. hydrochloric acid. The acid solution, filtered if necessary, is made alkaline with ammonia, and extracted twice with 40 c.c. of ether. The residue, on distilling off the ether in a tared flask, represents the amount of alkaloid in 10 grms. of the cacao leaves. The alkaloid is thus obtained as a colourless varnish, which crystallises after standing some time.—J. S.

Nux Vomica Seeds, Estimation of the Alkaloids in. C. C. Keller. *Schweiz. Wochenschr. Chem. Pharm.* 1895, 33, 152.

The following method is recommended by the author for the estimation of the alkaloids in the seeds of nux vomica:—12 grms. of the powdered substance are mixed with 80 grms. of ether and 40 grms. of chloroform in a dry flask of 200 c.c. capacity. After half an hour, 10 c.c. of 10 per cent. ammonia are added and vigorously shaken at intervals during an hour. 15–20 c.c. of water are then added in 2–3 portions to precipitate the drug. When the solution becomes clear after continued shaking, 100 c.c. are poured off and extracted in a separating funnel, first with 50 and then with 25 c.c. of 0.5 per cent. hydrochloric acid. The acid solution is then extracted three times with a mixture of 30 grms. of chloroform and 10 grms. of ether. The united extracts are evaporated in a tared flask, and the residue, which often retains chloroform, is repeatedly treated with 5 c.c. of ether, which is then boiled off, until this residue is obtained in the form of a white crystalline powder. The weight of the residue then represents the amount of alkaloids in 10 grms. of the seeds.—J. S.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Nitrogen Sulphide. R. Schenck. *Annalen*, **290**, [2], 171—185.

SULPHUR dichloride (250 grms.) is dissolved in dried benzene; the solution is cooled by iced water, and thoroughly dried ammonia gas carefully led in till no further evolution of heat takes place, and the mass becomes bright orange-red. The precipitate is quickly filtered, adhering benzene evaporated, ammonium salts washed out with water, and the residue crystallised from carbon bisulphide or tetrachloride. The benzene mother-liquor is concentrated by distillation to one-third of its bulk, when a further quantity of the substance crystallises out. In this way 33 grms. were obtained—about 45 per cent. of the theoretical yield. That still remaining in the mother-liquors is very difficult to separate from associated sulphur.

The nitrogen sulphide so obtained has the properties described by former observers—crystallises in fine orange-red needles, melts at 178° (earlier observers gave 160°), and explodes very readily on heating, friction, or percussion. Observations of the lowering of the freezing point gave a molecular weight agreeing with the formula N_2S_8 .

A constitution of nitrogen sulphide is given. The author regards it as a member of a new group of diazo bodies, containing pentad nitrogen, derivatives of the hypothetical compound $H_2N:NH_2$.—J. T. D.

Sulphoarsenates. R. F. Weinland and O. Rumpf. *Ber.* **29**, 1896, 1008—1012.

With a view to ascertain, if possible, the constitution of the sulphyarsenates the authors have prepared and described in this preliminary communication several sulphyarsenates. The sodium salt, Na_3AsSO_3 , is easily obtained by boiling a moderately concentrated solution of sodium arsenite with the calculated quantity of precipitated sulphur for half an hour, filtering from a slight excess of sulphur, and crystallising. The potassium and ammonium salts are prepared in a somewhat similar manner, the latter under pressure. Selenium can be added on to the ortho-arsenites just as readily as sulphur, whilst tellurium dissolves in a very concentrated solution of sodium ortho-arsenite, forming a red liquid which crystallises in a vacuum desiccator. The crystals could not be recrystallised from water, however, and there seems to be some doubt whether the substance so obtained was pure.—J. S.

Hypochlorous Acid, Reaction with Cobalt and Manganese Chlorides. Enthyme and B. Klimenko. *Ber.* 1896, **29**, 478.

The amount of Co_2O_3 produced in the reaction between hypochlorous acid and cobalt chloride is smaller when the relative quantity of hypochlorous acid is increased—the quantity of cobalt chloride remaining constant—than when the cobalt chloride is increased in proportion to the hypochlorous acid, and in the first case the most favourable ratio is expressed by $2CoCl_2 : 3HClO$. In the reaction with $MnCl_2$ the reverse is the case, more MnO_2 being produced when the oxidising agent is increased in proportion to the salt, the ratio $MnCl_2 : 2HClO$ giving the best result.

—A. C. W.

Phenanthrene and its Derivatives, New Syntheses of. R. Pschorr. *Ber.* 1896, **29**, 496.

o-NITROBENZALDEHYDE condenses with sodium phenylacetate in the presence of acetic anhydride to form a phenyl-*o*-nitrocinnamic acid—

This is reduced by ferrous sulphate in ammoniacal solution to the corresponding amine, which, when diazotised and shaken with copper powder in sulphuric acid solution, is transformed into β -phenanthrene carboxylic acid—

By using derivatives of *o*-nitrobenzaldehyde and phenylacetic acid, corresponding derivatives of phenanthrene will be obtained.—A. C. W.

Orthobenzoylphenol. P. Cohn. *Monatsh. für Chem.* **17**, 1896, [1], 102—109.

On heating phenylindoxazene with excess of fuming hydriodic acid and phosphorus in sealed tubes at 140° — 160° C. for 6—7 hours this substance is formed. The tubes were opened, the contents diluted with water, and the product shaken out with ether, which on evaporation left the impure ketone. To obtain it in a state of purity the liquid was dissolved in alcohol and sodium ethoxide added, when the sodium salt of orthobenzoylphenol separated. On decomposing this with hydrochloric acid, the *o*-benzoylphenol was obtained as a colourless oil, afterwards solidifying to crystalline plates, m. pt. = 36° . It is insoluble in water, but soluble in alcohol, ether, and acetic acid. Its composition is represented by the formula $C_{10}H_8O \cdot C_6H_5O(1:2)$.

—H. I.

Tartaric Acid, Levo-rotatory, Preparation of. W. Marckwald. *Ber.* **29**, 42—43.

THE method depends upon the fact that the cinchonine salt of levo-rotatory tartaric acid is more sparingly soluble in alcohol than that of the dextro-rotatory acid. In order to carry out the separation, a boiling aqueous solution of racemic acid has mixed with it, in small quantities, half the amount of cinchonine necessary to form the acid salt, sufficient water being added to give a clear solution. After standing one day the levo-rotatory salt crystallises out and is filtered off. The yield is about two-thirds of the theoretical. The filtrate, after standing two days, deposits the acid cinchonine salt of dextro-rotatory acid. The mother-liquor from this is halved, one part being exactly neutralised with caustic soda, the other with ammonia. The precipitated cinchonine is filtered off, the filtrate concentrated, and the sodium ammonium salt of dextro-rotatory tartaric acid crystallises out on cooling. The separation is carried on until the solution is inactive or faintly levo-rotatory. Unaltered racemic acid is separated by means of the lead salt, and the separation is then carried on anew as above. The levo-rotatory bitartrate of cinchonine can also be employed for the precipitation of pure levo-rotatory tartaric acid by decomposing the lead salt with sulphuretted hydrogen or sulphuric acid.—T. A. L.

Organic Acids; The Action of Light on, in the Presence of Uranium Salts. H. Fay. *Amer. Chem. J.* 1895, **19**, 269—289.

THE author has investigated the products of decomposition induced by the action of sunlight on certain organic acids in the presence of the uranyl salt of the respective acids. The following is a brief summary of his results:—

Oxalic Acid.—With oxalic acid and uranyl oxalate a precipitate is produced in two stages: (1) formation of uranous oxalate; (2) formation of the purplish-brown precipitate from the uranyl oxalate left in solution. The nature of the latter has not yet been determined, but it has been shown to contain carbon, and consequently cannot be a hydrated oxide as supposed. The formic acid observed when oxalic acid is decomposed must arise from the oxalic acid itself, since all attempts to build it up from water and carbon monoxide in presence of uranium salts have failed.

Tartaric Acid in presence of its uranyl salt forms an insoluble precipitate with uranium, the nature of which is not yet determined.

Acetic, Propionic, and Isobutyric Acids under the above-named conditions decompose into the hydrocarbons corresponding to the acids, and into carbon dioxide.

Malonic and Succinic Acids.—No satisfactory or definite results were obtained by the author in the case of these acids.—O. H.

Phenols, Toxicological Action of the. P. Binet. *Chem. Zeit.* 1896, **20**, 92—93.

From his experiments on the toxic action of the phenols, the author draws the following conclusions:—

Poisoning by phenol produces first a period of excitement, followed by one of collapse, accompanied by feeble spasmodic convulsions. Most substances belonging to the same chemical group act in a similar way. This action is not specially characteristic of the phenol hydroxyl groups, as it is also to

be met with in the benzene molecule, although to a less extent and with weaker poisonous effects.

The *Dihydroxyphenols* (*Pyrocatechol*, *Resorcinol*, and *Hydroquinone*) are much more irritant and in general more poisonous than phenol. In contradistinction to these the

Trihydroxyphenols (*Pyrogallol* and *Phloroglucinol*) have a much weaker action. *Pyrocatechol*, *hydroquinone*, and *pyrogallol* cause the formation of methæmoglobin.

The *Homologues of Phenol* (*Cresol*, *Thymol*, and *Orcinol*) are less active and in general less poisonous than the corresponding phenol, and this occurs to a greater extent the higher the molecular weight or the number of substituting alkyl groups; on the contrary, however, their action on the intestines is more powerful. Of the

Isomers of the Hydroxyphenols and Cresols, the meta-derivatives are least poisonous. The first esters of phenol (*anisol* and *phenetol*) produce trembling; in the case of *guaiacol* (methyl ester of *pyrocatechol*) the intense excitation of the hydroxyphenol has entirely disappeared. The presence of an alcohol or aldehyde group in the phenol molecule lessens the irritant and poisonous action.

Saligenin.—With the aldehyde of salicylic acid, the trembling greatly increases, in contradistinction to the corresponding alcohol (*saligenin*).

Benzyl Alcohol.—In the case of benzyl alcohol the convulsions and trembling disappear and the poisonous action is very slight. The isomerism with the cresols, the action of which is so different, makes the importance of the function of the hydroxyl groups evident.

The presence of an acid group in the phenol molecule lessens the poisonous action, but changes its properties.

Salicylic Acid.—Like *o-cresol*, salicylic acid shows critical stages of contraction and the difficulty in breathing which occurs in the case of benzoic acid.

Gallie Acid.—Gallie acid, like *pyrogallol*, produces no convulsions, but the deleterious effects on the blood are diminished.

Para-amidophenol is less irritant and also less poisonous than phenol, but it produces profound changes in the blood. The poisonous effect of the substitution products, diminishes, if the substituting groups are not in themselves poisonous.

—J. S.

Lanolinum Anhydricum, *Adeps Lane* and *Wool-Fat*. Von Cochenhausen. *Dingl. Polyt. J.* 1896, 299, 256.

The author, in a lengthy article, gives the results of tests on a sample of "*Lanolinum anhydricum*," two samples of *adeps lane*, and three samples of *wool-fat*.

The three samples of *wool-fat* were prepared from a large quantity of *wool-washing water* (from Australian wool). The wash water was treated with a solution of calcium chloride, and the precipitate formed filtered off and treated with pure acetone in a Soxhlet's extractor. The acetone solution was distilled and the residue treated several times with boiling water to remove the last traces of acetone. The *wool-fat* thus obtained was separated into three portions, viz.:—*Wool-fat I.*, about 70 per cent. of the total, the portion most soluble in acetone; *wool-fat II.*, about 20 per cent., the less-soluble portion; and *wool-fat III.*, about 10 per cent., the least soluble portion.

Wool-fat I. was of a faint yellow colour and of the same consistency as the *lanolinum anhydricum* and the *adeps lane*. *Wool-fat II.* was somewhat darker and thicker and more sticky than *wool-fat I.* *Wool-fat III.* was hard and solid at the ordinary temperature, and could be kneaded between the fingers without melting.

The author gives the figures obtained in tabular form, the following being of interest.

	Acid Value.	Saponification Value.
<i>Adeps lane I.</i>	0.67	..
" II.	0.88	82.43
<i>Lanolinum anhydricum</i> ..	1.81	89.97
<i>Wool-fat I.</i>	1.96	92.46
" II.	3.74	..
" III.	19.32	129.81

New Books.

UNSERE KENNNTNISSE IN DER ELEKTROLYSE UND ELEKTROSYNTHES ORGANISCHER VERBINDUNGEN. VON DR. WALTHER LÖB. Verlag von Wilhelm Knapp, Halle a. S. 1896. H. Grevel and Co., 33, King Street, Covent Garden, London. Price 2s.

This work is published in pamphlet form, and contains preface and 42 pages of subject-matter. The text is subdivided as follows:—I. ELECTROLYSIS AND ELECTROSYNTHESIS OF ALIPHATIC COMPOUNDS. a. Hydroxyl Compounds. b. Ketones. c. Acids. II. ELECTROLYSIS AND ELECTROSYNTHESIS OF AROMATIC COMPOUNDS. Phenols; Acids; Aniline; Goppelsröder's Researches. ELECTROLYTIC REDUCTION OF NITRO COMPOUNDS. ELECTROLYSIS OF ALKALOIDS, OF BLOOD, AND OF EGG ALBUMIN. ELECTROLYSIS AND ELECTROSYNTHESIS WITH ALTERNATING CURRENTS.

L'AMMONIAQUE, LES NOUVEAUX PROCÉDÉS DE FABRICATION. Par P. TRUCHOT. Bernard Tignol, 53bis, Quai des Grands-Augustins, Paris. H. Grevel and Co., 33, King Street, Covent Garden, London. 1896. Price 6 frs.

This work on Ammonia is a small 8vo volume in paper cover, containing 367 pages; which include preface, text, and table of contents. The subject-matter is illustrated with 31 woodcuts, and following it are:—1. A Classified List of Patents; and 2. A Bibliographic Index of Works and Researches on Ammonia. The text is sub-divided as follows:—I. Ammonia and Ammonium Salts. II. History of Ammonia and Ammonium Salts. III. Chemical and Physical Properties. IV. Manufacture of Ammonia. V. Working up Gas Liquors. VI. Manufacture of Liquor Ammoniac and Ammonium Salts. VII. Analysis of Ammonia and Ammonium Salts. VIII. Applications of Ammonia and Ammonium Salts. IX. Economics.

LES MÉDICAMENTS CHIMIQUES. Par LÉON PRUNIER, Professeur de Pharmacie Chimique à l'École Supérieure de Pharmacie, &c. Première partie. Composés Minéraux. Masson et Cie., 120, Boulevard Saint-Germain. 1896. H. Grevel and Co., 33, King Street, Covent Garden, London. Price 15 frs.

LARGE 8vo volume in paper cover, containing an introduction, table of contents, and text covering 623 pages. There is no alphabetical index, this being probably deferred until the appearance and completion of Part II., which is to appear about the end of 1896. The work is illustrated with 136 wood engravings. The individual treatment of the chemical substances described in the work may be illustrated by one example, viz., PHOSPHATE OF LIME:—1. Natural State; 2. Preparation; 3. Properties; 4. Analysis and Tests; and 5. Uses. The work is sub-divided as follows:—I. Monovalent Metalloids. II. Oxygen, Ozone, Sulphur. III. Nitrogen, Phosphorus, Arsenic, and Antimony. IV. Carbon and Charcoals. V. Aluminium, Zinc, and Iron. VI. Other Metals. VII. Distilled and Oxygenated Water. VIII. Potable Waters. IX. Mineral Waters. X. Iodides of Sulphur, Oxides of Nitrogen, Phosphide of Zinc. XI. to XVI. Various Acids. XVII. Carbonic Acid, Carbon Bisulphide, &c. XVII. to XX. Alkalies and Alkaline Earths. XXI. Magnesia, Zinc, and Manganese Oxides. XXII. to XXIV. Metallic Oxides. XXV. Sulphides. XXVI. Metallic Sulphides. XXVII. to XXXII. Chlorides, Bromides, and Iodides. XXXIII. Hypochlorites and Hypobromites. XXXIV. Chlorates, Bromates, and Iodates. XXXV. Hydrosulphites, Hyposulphites, and Sulphites. XXXVI. to XXXVIII. Metallic Sulphates, Alums, &c. XXXIX. and XL. Nitrites, Alkaline and Earthy Nitrates. XLI. and XLII. Hypophosphites and Phosphates. XLIII. Arsenites, Arseniates, Antimonites, Antimonates, and Borates. XLIV. to XLVI. Carbonates and Silicates. XLVII. Chromates, Permanganates, and Molybdates. XLVIII. Hydrocyanic Acid. XLIX. and L. Cyanides and Double Cyanides, Ferrocyanides, Sulphocyanides, and Nitroprussides.

PATENT OFFICE: THIRTEENTH REPORT OF THE COMPTROLLER-GENERAL OF PATENTS, DESIGNS, AND TRADE MARKS, with Appendices, for the Year 1895. (C. 8090.) Price 2½d.

This Annual Report is issued by the Comptroller of the Patent Office in pursuance of the requirements of the 102nd section of the Patents, Designs, and Trade Marks Act, 1883 (46 & 47 Vict. c. 57).

The following statement shows the total number of applications for patents, designs, and trade marks, and amount of gross receipts and expenditure in the years 1894 and 1895:—

Years.	Patents.	Designs.		Trade Marks.	Gross Receipts.	Gross Expenditure.
		Single.	Sets.			
1894	No. 25,386	No. 21,230	No. 1,025	No. 8,013	£ 181,855	£ 266,092
1895	25,065	20,507	910	8,272	187,012	260,671

* Including expenditure on account of new offices and buildings.

It is stated in the Report that in 1895, for the first time since the year 1885, the number of applications for patents showed no increase upon that of the preceding year, but, on the contrary, a decrease of 321. This decrease, however, was entirely due to a falling off of 676 in the number of applications accompanied by provisional specifications, those accompanied by complete specifications having increased in even more than the usual proportion, by 355. (See also this Journal, 1895, 702.)

Trade Report.

TARIFF CHANGES AND CUSTOMS REGULATIONS.

(From the Board of Trade Journal.)

PORTUGAL.

Tariff Modifications.

A despatch has been received at the Foreign Office from Her Majesty's Minister at Lisbon, transmitting copies and translation of a law, dated 27th April last, which imposes taxes on raw sugar, oils for food, artificial butter, clarified sugar, refined sugar, vegetable concrete oils, and candles, as follows:—

Art. 1. The "manufacture" and "consumption" taxes are levied on the products as specified in the law, made in the continental part of the kingdom and in the adjacent islands, and intended for consumption in the country.

Art. 2. Similar products to those taxed in virtue of this law, coming from foreign countries and cleared for consumption in this country, will pay the same taxes on clearance, saving any express provision to the contrary.

Art. 3. The following articles are subject to the taxes on manufacture and consumption, to which reference is made in Article 1:—

- Raw sugar.
- Fixed liquid oils for food.
- Artificial butter.
- Sugar clarified, sugar refined, whether it be amorphous or crystallised.
- Vegetable concrete oils.
- Candles of any kind or shape for lighting purposes.

Alterations in the Import Duty on Paraffin.

A despatch, dated 25th May last, has also been received, enclosing copy and translation of a new law regulating the import duty on paraffin, as follows:—

Art. 1. The words "paraffin purified" are struck out from the text of Article 149 of the Import Customs Tariff for Portugal and the adjacent islands, and these words are inserted in Article 99 of the said tariff, so that paraffin, either purified or not, presented for clearance after the publication of this law, will have to pay an import duty of 2 reis. (0.10d.) per kilo.

Art. 2. Any laws contrary thereto are hereby revoked.

RUSSIA.

Tariff Modifications.

Note.—Poud = 36 lb. avoirdupois. Gold rouble = 3s. 2d.

The Russian Department of Customs, under order dated the 7th (19th) May 1896, has notified the following classification of goods under the Russian Customs tariff:—

1. Glass powder (sparkling flakes of thin white glass or of glass coloured in the mass) approaching in character to enamel to be cleared under section 68. Duty, 3 roubles gold per pond.

2. Evaporating bowls of copper, lined with tin, used for manufacturing processes, to be cleared as worked copper ware under section 149. Duty, 4 roubles 32 copecks gold per pond.

3. Forks of aluminium, to be cleared under point 1 of section 158. Duty, 13 roubles 60 copecks gold per pond.

UNITED STATES.

Customs Decisions.

The following decisions relating to the classification of articles in the Customs tariff and the application of the Customs laws of the United States have recently been given by the Customs authorities in that country:—

Domestic coverings (carboys, iron drums, &c.) containing foreign goods, if of American manufacture, are free of duty as American manufacture, under paragraph 387.

Lanoline is dutiable at 25 per cent. *ad valorem*, under paragraph 58, as a medical proprietary preparation, non-alcoholic.

Chemical glassware, viz., Kjeldahl flasks, Norry flasks, Leyden jar, test tubes, Chevallier's creamometers, and other vessels of glass, some with glass stoppers and others without the same, are dutiable, if holding more than 1 pint, at three-fourths of one cent per pound. Articles of the above description holding less than 1 pint, including chemical thermometers, are dutiable at 40 per cent. *ad valorem*, under the respective provisions of paragraphs 88 and 90 of the Act of August 28, 1894, as other bottle glassware (than vials holding more than 1 pint) and articles or vessels of glass, engraved.

Soda-ash mixed with soap, soda-ash being the component material of chief value, is dutiable, under paragraph 67, at one-fourth of one cent per pound, the rate provided for soda-ash.

SWEDEN.

Tariff Modifications.

A despatch has been received at the Foreign Office from Her Majesty's Secretary of Legation at Stockholm, reporting the following changes in the Swedish tariff which have just been sanctioned by the Chambers.

Dextrin or Dextrin Gum (Dextrin och dextrin gummi).—The increase of the present duty of 17 ore per kilo. to 20 ore per kilo.

Platinum.—Certain articles used for technical purposes in which platinum is exclusively employed, hitherto charged an *ad valorem* duty of 10 per cent. under No. 362 of the tariff, to be admitted free under No. 428.

A communication has been received at the Foreign Office to the effect that the above changes will, probably, shortly come into effect.

EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

DEVELOPMENT OF SWEDISH MANUFACTURES.

In a report to the Foreign Office, dated 31st March last, Her Majesty's Consul at Stockholm gives interesting information respecting the development within recent years of the native manufacturing industries.

A considerable increase in production of iron and steel has occurred since 1891, the total value for the year 1893 being calculated at 2,777,777l.

The number of sawmills in Norrland is estimated at 225.

The wood-pulp industry has been increasing rapidly of late years. At the end of 1893 there were 93 factories in operation, producing in that year 96,000,000 kilos.

The development of the beet-sugar industry has been very rapid and successful. In the year 1890 there were only four factories in existence, but others have been set up each successive year, so that at the present time there are 18 in operation, producing nearly 50,000 tons of raw sugar annually.

GENERAL TRADE NOTES.

COMPULSORY CHARGES ON GERMAN WORKS.

Engineering and Mining Journal, May 30th, 1896, 519.

The reports and balance-sheets of the leading iron and coal companies published in the German technical journals clearly show how severe is the burden of taxes and contributions to compulsory benefit funds on German industry. In the case of the Gütehoffnungshütte, says the *Colliery Guardian*, one of the principal coal and iron companies, the taxes amounted last year to 5.08 per cent., and compulsory contributions to 1.62 per cent. on the capital.

This interesting subject has been studied in great detail by Mr. R. Effertz, director of the Königsborn Works, who has published some valuable statistics showing the tendency of these charges to increase year by year. He has selected for comparison three years, which appear to be well adapted for illustrating this increase. The year 1878 was the lowest point of the period of depression of the Rhenish-Westphalian coal trade, which extended from 1875 to 1889. The year 1885 was at the beginning of the growth of compulsory charges, while the year 1894 shows the full results of the innovation. For these three years the statistics are as follows:—

Year.	1878.	1885.	1894.
Output	Tons		
Cost of production..	£ 11,148,700	19,108,700	32,422,354
Cost, per ton	48. 11/2	48. 10/2	68. 5/2
Wages, total.	£ 1,571,540	2,719,863	5,912,597
Wages, per ton	2.750	2.846	3.665
Wages, proportion Per cent.	55.628	59.120	57.433
Wages, per man per shift.	2.703 to 3.771	2.225 to 3.118	2.890 to 3.791
Public charges, total	£ 133,051	227,808	501,400
Public charges, per Shillings ton.	0.232	0.238	0.557
Public charges, pro-Per cent.	1.760	1.652	8.740
Public charges, per Shillings man per year.	29.51 to 113.760	31.75 to 200.700	64.80 to 261.9

Under the head of public charges are included State taxes, local taxes, and mining taxes, the works, contributions to miners' fund, insurance fund, sick and pension fund, and contributions to benevolent funds, schools, and church. It will be noticed that the cost of production in 1878 and in 1885 was practically the same, the working efficiency being greater in the latter year than in the former. The annual output per miner is shown by the following figures published by the Society for Promoting Mining Interests:—

Year.	Output.	Number of Men employed.	Annual Output per Man.
	Tons.		Tons.
1878.....	19,208,942	71,364	258.3
1885.....	28,970,568	101,829	284.5
1894.....	40,613,973	154,136	263.5

The year 1894, however, showed an increase in the cost of production of nearly 33 per cent. compared with 1885, and of nearly 30 per cent. compared with 1878. The wages paid per ton increased in 1894 about 33.3 per cent. compared with 1878, and more than 28 per cent. compared with 1885. The average wage per man per shift in 1894 was 3.75s., that is, 35 per cent. more than in 1879, and 19 per cent. more than in 1885.

We now come to the ratio of the public charges to the cost of production. Calculated on the basis of a ton, these

charges in 1894 were 110 per cent. greater than in 1878, and 134 per cent. greater than in 1885.

Mr. Effertz's statistics are undoubtedly most suggestive, and cannot fail to throw doubt on the suggestion contained in the report of the Delegation of Employers and Workmen, organised to investigate the German iron trade, that the Continental employer has a fair equivalent for the burdens placed upon him by the State. In that report it is acknowledged that the serious increase of the cost of the accident assurance and other special workmen's funds has led to several proposals being considered with a view to either diminishing the amount of the indemnities and pensions, or to so altering the law itself as to reduce its pressure on the industrial works of Germany. The opinion is, however, expressed that the existence of these funds, involving, as they do, the care and protection of the employed by their employers, appears to secure harmonious relations between them.

SOAP AND ARSENIC IN TURKEY.

Chamber of Commerce Journal, May 1896, 88.

The *Bulletin* of the French Chamber of Commerce at Constantinople states that the consumption of soap in Constantinople is very considerable, and European towns of the same importance (nearly a million of inhabitants) would probably show a much smaller consumption. According to an estimate, the yearly consumption of soap in Constantinople amounts to between four and five million kilos. A German Consular report gives the following details respecting importation, viz.:—From Crete, 2,500,000 kilos.; from Metelin, 1,300,000 kilos.; from Aivali, 500,000 kilos.; from Marseilles, Trieste, and Italy 70,000 kilos. Several countries have endeavoured to enter into the trade, but without success, and it is stated to be impossible to compete with Crete and the islands of the Archipelago, which produce gigantic quantities of olive oil, and whose populations are regularly initiated in this industry. Although the celebrated Marseilles soap is sold, the quantity consumed is but trifling, as only Europeans (not Turks) use it.

The Ministry of Agriculture, Mines, and Forests has granted a concession for 99 years to Marshall Fuad Paeha for an arsenic mine discovered in the neighbourhood of Gulbachi, Sandjak of Bordour. The mine covers an area of 390 djirids (hectares).

PRODUCTION OF BASIC STEEL, 1878-93.

Engineering and Mining Journal, May 30th, 1896, 518.

Since the close of 1893, when the patents ran out, no figures of the output have been systematically collected, though it has been ascertained by the British Iron Trade Association that 415,917 tons were made in Great Britain in 1894. Some endeavours have been made to collect the statistics for foreign countries since 1893, but these have not as yet met with success. The figures given below, however, are complete up to 1893. There is good reason to believe that a considerable extension of the manufacture is going on abroad, now that no royalties have been paid, and the demand for steel is rapidly increasing with the revival of trade.

Year.	England.	Germany.	Luxemburg.	Austria.
	Tons.	Tons.	Tons.	Tons.

RAMIE CULTIVATION IN JAMAICA.

Imperial Institute Journal, June 1896, 215.

From the statement of a correspondent writing to the *Textile Mercury* from Kingston, regarding the efforts of Sir Henry Blake to introduce the cultivation of ramie or rhea fibre into Jamaica, it appears that the difficulty of separating the fibre economically has been overcome with some degree of success. Without the aid of machinery, and simply by a process of hand labour, after the dried plant had been treated by a chemical solution, 732 lb. of fibre were produced. The labour used was that of the boys of the Government Industrial School, which is in close proximity to the Botanical Gardens. In a working day of eight hours the average amount of wet fibre separated by each boy was 27 lb., or $4\frac{1}{2}$ lb. of dry ribbon, and, of course, with practice the amount would be materially increased. The cost of boy labour in Jamaica is 6d. to 9d. per diem: female, 9d. to 1s.; and men's, 1s. 3d. to 1s. 9d. The ramie ribbon so decorticated was sent to Messrs. Dunlop, merchants, London, who stated that all the experts declared unanimously that the samples were the best ever sent to London. Messrs. Dunlop further reported that in the state in which the ribbon was sent over they could find buyers of from 60 to 100 tons per month. They had sold part of the sample at 36l. per ton, and could have realised 10 tons at once. They were convinced that if the growers in Jamaica were in a position to produce large quantities, ample sales at remunerative prices would be made. The demand was great, and they would strongly advise the cultivation of the product in Jamaica. Already, concludes the *Textile Mercury's* correspondent, many of the planters have taken up the ramie culture, and should the project prove successful, a revolution in the fibre market may be anticipated.

THE CHEMICAL INDUSTRY IN GERMANY.

Chemist and Druggist, June 13th, 1896, 839.

The British Consul at Mannheim does not draw a very bright picture of the condition of the chemical industry in his district, which possesses some of the biggest chemical factories in Germany. "The chief feature of the industry in 1895," he says, "has been the continued fall in prices almost all along the line. The break-up of the South German Sulphuric Acid Convention caused a heavy decline in price. Sharp competition set in among the manufacturers. The unfortunate condition of agriculture in general prevented the artificial manure makers from doing a prosperous trade. One factory began making superphosphates simply in order to turn its make of sulphuric acid to account. Trade with Spain, that used to comprise chiefly magnesia and hyposulphite of soda, has ceased almost entirely. In Germany the chemical industry is being overdone and overrun. Many new factories are being opened without there being any field

for their production, and consequently prices of many articles are ruinously low. A number of newly invented pharmaceutical products have been put on the market during the year, but it is complained that most are introduced before being properly tried. The quinine factory at the Waldhof reports a satisfactory year, with extended connections and increased business at home and abroad, but, owing to the Customs war between Germany and Spain, business with the last-named country has fallen off greatly. This was the more felt since the consumption of quinine, owing to the war in Cuba, has greatly increased, and was covered by the French factories. The sale of alcoholic preparations was considerably affected by the changes in the excise impost, and export prices for such products were purely speculative, manufacturers being quite uncertain whether drawback to the full amount would be allowed. The new tax is said to require a revision of the import duties on alcoholic preparations, since, as things are, both foreign countries and the chemical factories in the free-port district of Hamburg can manufacture such products cheaper than Germany itself. Other countries are, therefore, in the position of being able to beat Germany abroad, and to compete with it in its home market." The report may be coloured somewhat too darkly, but it tends to show how exaggerated is the belief that the chemical industry of Germany is made up of factories earning 25 per cent. dividends, and it also confirms, what is generally known to those behind the scenes, that much of the export trade of the country is done without any profit whatever, or even at a loss, in order to get rid of over-production.

NEW RAILWAY REGULATIONS FOR CONVEYANCE OF ETHER, 1896.

Inflammable Liquids.

Ether, in luted and tied-over bottles, packed in sawdust in cases of sufficient strength, or in hermetically sealed tins, packed in sawdust in cases or casks of sufficient strength, each package containing not more than 28 lb. of ether, and the gross weight per package not to exceed 84 lb., minimum charge, 5s.

Specification of Iron Drum for the Carriage of Ether and Gasoline, Contents of which shall not exceed Ten Gallons.

1. The drum is to be not more than 14 ins. in diameter, and is to be made of tinned sheet iron, the body of No. 20 B.W.G. plate, with a sunk longitudinal grooved joint well filled with solder. The ends are to be of No. 19 B.W.G. plate, with a camber of not less than $\frac{1}{4}$ in., flanged at the edges, and let into the body of the drum 1 in., with the bulge outwards and the flange inwards, strongly sweated with solder, and afterwards well floated with solder all round. The drum is to be strengthened by three bands of iron, No. 14 B.W.G. (the ends of which are welded or riveted together), one band $1\frac{1}{2}$ ins. wide round the middle of the drum, and one 2 ins. wide round each end, each band to be firmly secured to the drum by solder. A brass screwed collar and plug is to be let into the top of the drum, and secured by a washer soldered round the collar inside. Painted drums must be white.

2. Each drum, when new, must be tested by hydraulic pressure of 40 lb. per sq. in., without showing signs of injury or leakage, also whenever it shows signs of damage or deterioration, and the test must be repeated at least once every year.

3. When filling the drum, an air space equal to at least one-tenth the capacity of the drum must be left. After filling, and before being hauled to the railway company for conveyance, the senders must test each drum by submersion in a tank of water heated to not less than 130° F., to ensure there is no leakage.

4. The screw plug of each empty drum must be securely fastened in its place before the empty drum is returned.

5. Damaged drums will not be accepted for conveyance.

A further regulation is to the effect that drums must be sent naked—that is, not packed in casks or barrels—so that no risk of bad packing of glass containers in casks or barrels may be possible.

EUROPEAN SUGAR INDUSTRY FOR THE YEARS 1891 TO 1895 AND 1895 TO 1896.

Monthly Patent List.

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

10,763. F. Svoboda. Improvements in and connected with Siemens' regenerative furnaces. May 19.

10,983. J. G. Chamberlain. Improvements in apparatus for softening and purifying water for feeding boilers and for other purposes. May 21.

11,136. E. C. Mills and J. G. Chamberlain. Improvements in filters for extracting grease and other impurities from feedwater for steam boilers. May 22.

11,345. A. Gates. Improvements in apparatus for mixing liquids. May 23.

11,621. H. Maxim. Improvements in methods and apparatus for effecting the separation of gases. May 28.

11,633. S. K. Welch. Improvements in filtering apparatus. May 28.

11,739. O. Guttman. Improvements in apparatus for softening and purifying water. Complete Specification May 29.

11,828. T. Bradford. Improved apparatus for drying fabrics and other materials. May 30.

11,963. H. G. Watel. Improvements in transmitting the indications of thermometric, hygrometric, barometric, or other instruments. June 2.

12,045. H. Seek. Improvements in machines for separating light from heavy substances. Complete Specification. June 2.

12,109. P. Hereng. Carburetting apparatus. June 3.

12,557. S. J. Norton and H. A. Stenning. Improvements in apparatus for compressing air and other gases. June 8.

12,572. S. G. Merrick and H. L. Washburn. Improvements in and relating to vapour condensers, and apparatus for destroying noxious fumes, recovering by-products from distillation, and like purposes. June 8.

12,643. E. Porak. Method of and apparatus for washing and compressing sulphurous acid and other gases or fumes. Complete Specification. June 9.

12,889. W. S. Akerman. See Class IX.

COMPLETE SPECIFICATIONS ACCEPTED.*

1895.

12,184. A. W. Stokes. Apparatus for determining volumetrically the amount of fat in milk or other articles. June 10.

13,188. A. Barr and W. Stroud. Apparatus for the production of high vacua. June 17.

13,867. Sir W. Arrol and W. Foulis. Apparatus for charging gas and other retorts. June 17.

13,896. F. Barmann-Zix. Method and apparatus for the production of superheated steam. June 3.

14,456. H. R. Chubb. Machinery applicable for filtering, condensing, and absorbing air, smoke, fumes, and other gases. June 17.

14,852. E. Theisen. Apparatus for evaporating or distilling liquids. June 10.

14,971. F. Willis. An improvement in the construction of gas furnaces for enamelling, assaying, milling, &c. June 17.

24,709. J. L. A. Aymard. Improvements in sterilising apparatus. June 3.

1896.

3141. J. M. Boustead. Improved apparatus for desiccating. June 3.

7802. A. T. Pfeiff. Improvements in apparatus for sterilising milk, cream, and other liquids by means of steam. June 17.

7878. W. R. Jones. Improvements in furnaces. June 3.

8198. A. S. Bryce, jun. Improvements in packing for hydraulic apparatus. June 3.

9557. H. Herzel. Improvements in or connected with the overflow pipes of distillation and absorption columns. June 17.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

10,673. C. A. Finch and H. J. Ingle. Improved apparatus for regulating the supply of illuminating gas and enriching the same, and improved composition for such enrichment. May 18.

10,725. G. Webb, jun., and J. W. Kelly. Improved apparatus for automatically generating gas. Complete Specification. May 18.

10,728. J. Swinburne. Improvements in generating acetylene from carbides. May 19.

10,822. H. Kirkham. Improvements in scrubber washers for removing impurities from gas. Complete Specification. May 19.

10,830. O. Knofler. Improvements in or relating to the manufacture of mantles or the like for incandescence gas-lighting. May 19.

10,862. S. Falk. Improvements in the treatment of mantles for incandescence gas-lighting. May 19.

10,965. A. E. Brunne. Improvements relating to the means for preparing or finishing mantles for incandescence gas burners. May 21.

11,109. C. Weygang. Improvements in the application of artificial fuel. May 22.

11,267. T. Thorp and T. G. Marsh. Improvements in apparatus for producing acetylene gas. May 23.

11,268. T. Thorp and T. G. Marsh. Improved treatment of calcic carbide for the production of acetylene gas. May 23.

11,269. T. Thorp and T. G. Marsh. Improvements in the method of and means for charging acetylene gas generators. May 23.

11,350. J. H. H. Duncan and D. W. Sugg. Improvements in the manufacture of incandescence mantles for gas and vapour lamps. May 23.

11,330. The Economical Gas Apparatus Construction Co., Lim., and L. L. Merrifield. Improvements in apparatus for the manufacture of carburetted water gas. May 27.

11,581. G. Moreau and A. Poulhies. Improvements in gas-lighting. May 27.

11,632. J. E. Goldschmid and C. Dellwik. An improved manufacture of water gas. May 28.

11,706. E. F. J. C. Bauweraerts. An improved process and apparatus for purifying acetylene gas. Complete Specification. May 29.

11,707. E. F. J. C. Bauweraerts. An improved burner for acetylene gas. Complete Specification. May 29.

11,708. E. F. J. C. Bauweraerts. Apparatus for the generation of acetylene gas. Complete Specification. May 29.

11,737. E. Claesolles. Improvements in apparatus for the production and storage of acetylene gas for illuminating purposes. Complete Specification. Filed May 29. Date applied for Jan. 24, 1896, being date of application in Spain.

11,938. T. Hawkins, A. Wellby, and J. W. Carr. An improved apparatus to be used for the production of gases to be used for fuel heating and steam engines and driving gas engines. June 2.

11,951. J. Meikle. Improvements in treating peat, coal, and other carbonaceous substances for the obtainment of illuminating gas. June 2.

11,955. W. Young and G. R. Hislop. Improvements in the production of illuminating gas from liquid hydrocarbons, and in apparatus therefor. June 2.

12,016. M. C. A. Fourchette. Improvements in apparatus for generating acetylene gas. June 2.

12,047. M. C. A. Fourchette. Improved method of and apparatus for generating acetylene gas. June 2.

12,055. G. Kern. Improvements in or relating to apparatus for producing acetylene. June 2.

12,245. W. P. Thompson. Improvements in the separation of gases of different specific gravity, and in apparatus therefor. June 4.

12,351. W. W. Baggally. Improved appliances for incandescent gas lighting. June 5.

12,430. A. Arter. Improvements in and relating to the treatment of gas for illuminating and other purposes. June 6.

12,527. D. Hancock, J. B. Craig, and A. H. Hancock. Improvements in or connected with the treatment of carburetted air or gas for heating purposes. June 8.

12,535. O. Imray.—From F. Brunek and Co. Improvements in horizontal coke ovens. June 8.

12,612. J. W. Lea and J. H. Perrius. Improvement in incandescent mantle protectors. June 9.

12,628. A. Bryce. A universal fuel injector. Complete Specification. June 9.

12,662. A. Tobler. Apparatus for the automatic generation and distribution of acetylene gas. June 9.

12,683. H. A. Daroy. Improvements in the manufacture or production of acetylene gas, and in apparatus therefor. Complete Specification. June 9.

12,771. C. Whitfield. Improved process and apparatus for manufacturing producer and water-gas. June 10.

12,788. R. R. Gibbs. Improvements in or relating to the generation and storage of acetylene. June 10.

12,840. H. Hellewell. Improvements in the preparation or manufacture of artificial fuel. June 11.

12,900. S. Earl. An improved apparatus for the manufacture of acetylene gas. June 11.

12,912. T. Thorp and T. G. Marsh. Improvements in and connected with the method of and apparatus for treating acetylene prior to combustion. June 12.

13,115. C. P. Choquette and A. M. Morin. Improvements in acetylene generators. June 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

10,356. J. T. Key and W. S. Key. An improved system for the manufacture of coke, the construction of coke ovens, and the recovery of by-products from same. May 27.

10,917. H. Riché. Manufacture of gas and apparatus therefor. June 3.

12,356. T. Thorp and T. G. Marsh. Apparatus for the production of heating and illuminating gas. June 3.

12,332A. G. A. Cannot. Manufacture of briquettes for fuel from peat. June 17.

13,750. T. L. Willson. Manufacture of illuminating gas. June 3.

13,766. T. L. Willson. Production of illuminating gas. June 3.

14,759. M. G. Sykes. Production of fuel. June 17.

14,855. A. K. Huntington. See Class VII.

14,974. C. Jacobsohn. Improvements in night-lights. June 17.

16,139. J. Laycock. Apparatus for washing and scrubbing gas. June 17.

1896.

7438. E. H. C. Oehlmann. Incandescent gas burners. June 3.

7901. J. M. Mitchell. Apparatus for mixing air and gas. May 27.

8239. C. Gautzsch. Apparatus for producing illuminating gas. June 3.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

10,827. J. Y. Johnson.—From The Chemische Fabrik Griesheim. A process for the manufacture of di-ortho-nitro-toluene, enabling ortho-para-di-nitro-toluene and tri-nitro-toluene to be obtained at the same time. May 19.

11,309. Read, Holliday, and Sons, Lim., and H. Dean. Improvements in the manufacture of basic colouring matters. May 23.

11,370. Read, Holliday, and Sons, Lim., J. Turner, and J. Turner. Improvements in the production of colouring matters. May 26.

12,142. S. Pitt.—From L. Casella and Co. Production of polyazo dyestuffs. June 3.

12,204. W. H. Claus and A. Rée. Production of new colouring matters. June 4.

12,534. H. W. Langbeck. Improvements in the manufacture of materials for indelibly marking paper and fabrics. June 8.

12,556. S. Pitt.—From L. Casella and Co. Production of dyestuffs suitable for dyeing wool. June 8.

12,922. A. G. Green and A. Wahl. The manufacture and production of new cotton colouring matters. June 11.

13,093. H. R. Vidal. An improved manufacture of dyes. Date applied for, June 3, 1896, being date of application in France. June 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

13,949. C. D. Abel.—From A. Fisches-er and Co. Manufacture of phthaleines by the action of mixed anhydrides. June 10.

14,382. O. Murray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Manufacture of meta-nitranilino-sulpho acid and its analogues.

14,686. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. The manufacture or production of anthraquinone derivatives. June 10.

15,242. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik. The manufacture and production of black colouring matters of the anthraquinone series, suitable for directly dyeing cotton in the cold bath. June 10.

17,402. W. Clarke. Improvements relating to the treatment of mangrove bark for the obtainment therefrom of pure solid tannin, dye, and cutch. June 3.

1896.

8770. H. Murray.—From The Badische Chemical Works, Bindeschedler. Manufacture of alkyl glycolic acid derivatives of paramidophenol ethers. June 10.

9912. E. Ritter von Portheim. Process for producing black azo dyestuffs on the fibre. June 17.

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATIONS.

10,868. O. A. Berend and the "Lehner" Artificial Silk Co., Lim. Improvements in the production of artificial silk. May 20.

11,371. W. R. Jones.—From T. A. Jones and D. Gibb. An improved machine for scouring wool or other fibrous materials. May 26.

11,892. G. R. Smith. Improvements in the method of impregnating wool and other fibrous material with oil, water, and the like, and in apparatus therefor. May 30.

12,115. W. P. Dreaper and H. K. Tompkins. Improvements in the manufacture of artificial silk. June 3.

12,693. S. Bennett. Improvements in the treatment of wood, paper, fabrics, fibres, and like materials impervious and inalterable by moisture and climate and other influences. June 9.

12,897. L. Frankenstein. Improvements in finishing or ornamenting the surface of waterproof fabrics. June 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

14,453. G. C. Dymond.—From La Société Leblois, Piceni, and Co. An improved process for the treatment of textile and other materials, and apparatus therefor. June 20.

14,781. G. Loppens and H. Deswarte. Improvements in and connected with retting or steeping flax and hemp. June 10.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

10,753. J. D. Asquith. Improvements in washing and scouring machines for washing and scouring textile fabrics. May 19.

10,936. A. F. B. Gomes. Improvements in bleaching certain vegetable fibres, more especially those of the urtica family. May 21.

11,828. T. Bradford. See Class I.

12,500. H. Schirp. Improvements in dyeing, washing, and rinsing apparatus for textile goods. Complete Specification. June 8.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

10,842. J. Y. Johnson. Improvements in the preparation of specially heavy ammonia-soda. May 20.

11,160. S. J. Payne. Improvements in obtaining pure alumina, sulphate of alumina, and silica from clays. May 22.

11,326. E. A. Williams and J. F. C. Williams. Improvements in and connected with the manufacture of cyanides. May 23.

12,104. E. Paul. Improvements relating to heating and evaporating brine. June 3.

12,765. J. Milne. Improvements in dissolving and drying phosphates and other substances. June 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

13,461. T. T. Best, A. Kayd, and J. Brock. Manufacture of chlorine from hydrochloric acid gas. June 17.

14,122. L. Blackwell. Improved means for treating sodium chloride for the production of bleach and other products. June 3.

14,855. A. K. Huntington. Manufacture of hydrocyanic acid. June 10.

15,966. A. Frank and N. Caro. Production of cyanogen compounds, and to the preparation of materials for use therein. May 27.

15,116. J. Pileger. A process for the manufacture of cyanides. June 10.

1896.

10,222. A. von Ral and J. Rosenfeld. Manufacture or production of cyanogen compounds. March 25.

9544. P. Jensen.—From D. Cappelen and H. Cappelen. Process for purifying chlorine gas. June 17.

VIII.—GLASS, POTTERY, AND ENAMELS.

APPLICATIONS.

11,522. H. Hayward. Improved system of glazing. May 27.

11,803. J. E. Heath and J. J. Adams. Improvements in or relating to encaustic or similar tiles. May 30.

11,856. H. Cartledge. Improved construction of potters' kilns. Complete Specification. June 1.

12,923. B. A. Knappett and J. F. Charlesworth. Improvements in and relating to shading and colouring glass and other materials. Complete Specification. June 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

10,911. E. Bohm. Production of plaques and similar articles from glass. June 10.

14,454. H. Sturm. Improvements in or connected with apparatus for moulding and drawing ceramic articles. June 17.

15,139. J. E. Bringley. Machinery used in the manufacture of ceramic tiles. June 3.

18,946. A. J. Boulton.—From P. A. J. Gasse. Improvements in or relating to painting or printing upon earthenware. June 17.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

10,815. La Roy Freese Friffin. A new substance especially applicable for making building blocks, slabs, and the like. May 11.

10,841. H. Schneider. Improvements in and relating to the manufacture of paving material and slabs. Complete Specification. May 19.

11,182. W. P. Thompson. Improvements in the method of preparing or treating wood. May 22.

11,212. J. Walker. An improved cement. May 23.

11,682. J. Dixon and A. Reynolds. Improvements in the manufacture of silica bricks, or other highly refractory bricks. May 29.

11,738. H. H. Lake.—From M. Friedheim. Improvements in plastic substances used for building and decorative purposes. May 29.

11,847. J. E. Brindley. Improvements in the manufacture of tiles and quarries. June 1.

12,116. C. Mason. Improvements in the construction of asphaltic pavements. June 3.

12,135. E. Nelson. Improvements in the manufacture of damp-proof material applicable for roofing and for other purposes. June 3.

12,169. A. J. Boulton.—From M. Thys. Improvements in or relating to the manufacture of artificial stone. Complete Specification. June 3.

12,368. W. Owen. An improved manufacture of artificial stone, marble, and the like. June 5.

12,425. L. Mack. Improvement in the proceeding for the production of quick-setting (hardening) mortar of hydraulic gypsum. Complete Specification. June 6.

12,673. C. Marson. An improved cement for plastering on walls or ceilings. June 9.

12,674. C. Marson. An improved material for covering walls or any other article with glass in place of ordinary plastering. June 9.

12,693. S. Bennett. See Class V.

12,889. W. S. Akerman. Improvements in kilns for burning cement, lime, and other materials. June 11.

12,925. J. Russell. Improvements in or relating to blocks suitable for paving and other purposes. June 11.

13,077. H. Wood. Improvements in the preparation of material suitable for use as cement, mortar, or in the manufacture of bricks or blocks for building purposes. June 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

7591. W. Jones and H. Jones. Construction of fireproof tile ceilings, partitions, and the like. March 4.

15,283. J. H. Lester and T. E. Thomlinson. Improvements in treating certain waste materials to produce valuable products, such as plaster or stiffening, weighting, and whitening materials therefrom. June 17.

1896.

7032. A. M. Clark.—From The Electric Fireproofing Co. Method and apparatus for treating wood. June 17.

X.—METALLURGY, MINING, Etc.

APPLICATIONS.

10,797. A. E. Woodhouse. An improved method of heating steel bands or strips and wires in the processes of hardening and tempering them. May 19.

10,864. B. Politzer. A process for protecting metallic surfaces against chemical and atmospherical action. May 19.

11,048. H. V. Holden. Improvements in casting armour plates and moulds therefor. May 21.

11,241. W. Preston and F. D. Docker. An improved method of preventing iron and steel from rusting. May 23.

11,245. Davies Bros and Co. Lim., E. A. Davies, and S. T. Thomas. Improved means for use in preparing metal sheets for the purpose of galvanising them or otherwise coating them with metal or metallic alloy. May 23.

11,464. S. O. Cowper-Coles. Improvements in and apparatus for the treatment of ores and the separation of the metal or metals therefrom. May 26.

11,465. S. O. Cowper-Coles. Improvements in or connected with means for separating metals from cyanide solutions. May 26.

11,555. D. A. Peniakoff. A process of manufacture of sulphide of aluminium which may or may not be combined with other sulphides (or sulphurets). May 27.

11,717. W. T. Lougher. The Swansea process of covering steel and iron plates with copper sheeting. May 29.

11,718. O. Imray.—From Oberschleische Eisenbahn-Bedarfs Actien Gesellschaft. Basic lining for mixing apparatus for pig iron or steel. May 29.

11,833. R. A. Hadfield. An improved method of toughening or softening manganese steel castings. May 30.

11,839. A. S. R. Robinson. Improved method and machinery or apparatus for extracting gold from crushed ore or material containing it. May 30.

11,848. J. H. Gartrell. Improvements in nickel muffles. June 1.

11,927. J. B. Torres. Improvements in and connected with the reduction, manufacture, and refining of metallic compounds, metals, and alloys. June 2.

12,053. H. R. Angel. Invention for the recovery of zinc up to a high grade from refractory ores. June 2.

12,056. M. L. Ross.—From E. Oberle. Improvements in or relating to the manufacture of refractory metallic threads. Complete Specification. June 2.

12,106. E. Govett. An improved process for treating refractory ores. Complete Specification. June 3.

12,200. A. Trenk. A new or improved process and apparatus for extracting gold. June 4.

12,255. M. B. Zerener. Improvements in or relating to the precipitation of precious metals from their cyanide solutions. June 4.

12,287. W. Van Wart, F. W. Popp, and J. J. Bradley. A certain new or improved metal or admixture of metals. June 5.

12,328. J. C. Bull. Improvements in alloys. June 5.

12,396. E. A. G. Street. Improvements relating to the fusing of chromium and similar metals, and to the manufacture of alloys of such metals. June 6.

12,467. E. A. G. Street. Improvements in the manufacture of alloys. June 6.

12,591. J. B. Torres. Improvements in and connected with the treatment of gold and other ores, and in apparatus therefor. June 9.

12,782. A. Wilson and F. Stubbs. Improvements in carbonising iron and steel. June 10.

12,905. A. Wilson and F. Stubbs. Improvements in hardening armour plates, and in apparatus therefor. June 11.

12,933. C. Sharland.—From L. R. Seammell. An improved process for the treatment of refractory gold and silver ores. June 12.

12,934. C. Sharland.—From L. R. Seammell. An improved process for the treatment of refractory gold and silver ores. June 12.

12,935. C. Sharland.—From L. R. Seammell. An improved process for the treatment of refractory gold and silver ores. June 12.

13,034. J. B. Torres. Improvements in or relating to the extraction of gold and other metals from ores and the like. June 13.

13,111. E. A. G. Street. Improvements in the manufacture of chromium and similar alloys. June 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

10,671. J. C. Bull and R. E. M. Lagerwall. Manufacture of metal alloys. May 27.

11,894. F. S. D. Scott. A gold-saving machine, suitable for the treatment of auriferous sand, alluvial deposits, pulverised ore, and the like. June 3.

12,174. M. Gledhill. Manufacture of steel plates. May 27.

12,455. A. A. Dickson. Improvements in the reduction of metallic sands and pulverised ores. June 17.

13,537. M. Crawford. A process for precipitating gold and other precious metals from solutions used for extracting such metals from their ores. May 27.

15,959. W. L. Wise.—From the Aluminium-Industrie Actien Gesellschaft. Manufacture or production of granulated aluminium and magnesium. June 10.

20,342. R. Maclaren, D. Hughes, and W. Davies. An improvement in apparatus or machinery for coating metal sheets with tin, lead, or other coating metal or alloy of metals. June 17.

23,414. H. Langen. An improved process of separating metals having different melting points. June 3.

23,707. H. S. Blackmore. Process for producing decomposing, converting, or transforming compounds, and reducing metallic compounds so generated to metallic state. June 17.

1896.

7358. H. L. Haas. Process of nickel plating. June 17.

8072. W. T. Whiteman.—From the Compagnie Générale L'Alumine Exploitation des Brevets F. Raynaud. A new or improved process for the treatment of aluminous ores and silicious matters. May 27.

8368. T. Doherty and P. D. Crear. Process of melting iron. May 27.

8946. H. H. Lake.—From Hawkins' Steel Co., Ltd. Purifying and refining iron and apparatus therefor. June 3.

8959. J. D. Grey. Improvements in the method of and apparatus for preparing sheet iron and steel in the manufacture of tin andterne plates, or for galvanising. June 3.

9552. W. P. Thompson.—From W. E. Harris. A new or improved method of and apparatus for treating and annealing sheet metal. June 17.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

10,718. H. O. Tudor.—Improvements in the manufacture of positive lead electrodes for electrical accumulators. May 18.

10,811. A. J. Marquand and E. Hancock. Improvements in the production of electrodes suitable for secondary batteries. May 19.

11,133. G. Bell and G. W. Bell. Improvements in or connected with apparatus for the electrolytic decomposition of liquids. May 22.

11,212. T. Clark. Improvements in dry cells for galvanic batteries. May 22.

11,338. E. A. G. Street. Improvements in electrodes for electrolytic purposes. May 23.

11,627. E. J. Clabbe, A. W. Southey, and The Electric Motive Power Co., Ltd. Improvements in secondary batteries. May 28.

11,730. W. P. Thompson.—From The Elektra Galvanoplastische Anstalt, H. Teith, and A. Floeck. An improved apparatus for producing galvanic or electrolytic depositions. May 29.

11,732. E. Grunwald. An improved plate for storage batteries. May 29.

12,149. T. J. Holland. Improvements in electrolytic apparatus. June 3.

12,227. L. Epstein. An improvement in secondary voltaic batteries. June 4.

12,250. C. Marsehner. Improved plates for secondary galvanic batteries and a method of producing the same. June 4.

12,312. J. L. Dobell. A new or improved apparatus for electrically smelting metals, and for other purposes. June 5.

12,398. L. Davis. A flexible crystal covering for electrical conductors. June 5.

12,549. D. G. Fitzgerald. Improvements in and in the manufacture of elements for secondary batteries. June 8.

12,983. R. N. Lucas. An improved grid or plate for secondary batteries. June 12.

13,079. W. P. Thompson.—From C. C. Lesenberg. Improvements in or connected with dry batteries and the like. Complete Specification. June 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

- 10,951. E. Freund. Secondary batteries. June 10.
 11,944. C. Raleigh. Electrolytic deposition of metals and means applicable therefor. June 17.
 14,312. J. Kolb and A. D. A. Lambert. An improved electrolysis apparatus. June 10.
 17,825. W. H. Beck.—From J. Johnson, J. H. Robertson, J. H. Cro-man, and W. H. Jewell. A new or improved porous plate, body, or electrode. May 27.

1896.

719. B. Wilcox.—From La Société L'Accumulateur Fulmen. Improvements in electrical accumulators or storage batteries. June 10.
 1054. D. G. Fitzgerald and W. C. Bersey. Improvements in voltaic batteries. March 25.
 1238. P. A. Newton.—From C. Willms.
 4434. F. King. Improvements in or connected with moulds for use in the manufacture of secondary battery plates or supports. May 27.
 5506. P. F. Ribbe. Improvements in electric accumulators. June 17.
 6981. J. Entwistle.—From S. N. Smith and E. S. Baring-Gould. Electric batteries. June 17.
 8660. F. U. Schneider. Construction of cells for electric accumulators. June 3.
 8695. W. Majert. Electrodes for accumulators. June 3.

XII.—FATS, OILS, AND SOAP.

APPLICATIONS.

- 10,681. J. Aseough. Improvements in the manufacture of soaps and saponaceous compounds. Complete Specification. May 18.
 10,837. J. Glatz and O. Lugo. Improvements in the production of glycerine and caustic soda from soap lyes. Complete Specification. May 19.
 10,955. C. Drummond. An improved soap composition for washing flannel and the like. May 21.
 11,112. A. Beveridge and J. Pursell. An improved method for the rendering and clarifying of fats. May 22.
 12,073. J. M. C. Grierson. Improvement in soaps. June 3.
 12,166. R. Haddan.—From J. Muss. A dry lubricant and method of producing the same. June 3.
 12,228. F. J. Reinisch and H. Lesser. The manufacture of an improved lubricant. June 4.
 12,953. H. W. Wilson. An improved soap or cleansing agent. Complete Specification. June 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

- 11,972. J. Peters. A mixing and purifying machine for the manufacture of hot neck grease. June 17.
 14,978. F. N. Turney. Improvements in degreasing and cleansing wool cotton waste, and like materials, and in apparatus therefor. June 17.
 17,239. G. Mitchell. Process and apparatus for separating and otherwise treating oils and like liquids. May 27.
 19,163. R. E. Green. Manufacture of soap. June 10.

XIII.—PAINTS, PIGMENTS, VARNISHES, RESINS, INDIA-RUBBER, Etc.

APPLICATIONS.

- 10,639. A. Hobbs. Improvements in the manufacture of india-rubber, vulcanite, and other products wherein india-rubber and vulcanite are employed. May 18.
 10,890. T. H. Cobley. Improvements in the manufacture of white lead and other compounds of lead. May 21.
 10,925. T. B. Rawlins. Improvements in anti-fouling and anti-corrosive compositions. May 21.
 11,138. L. Grote. Process for the manufacture of plastic objects from fibrine or fibrous produce. May 22.
 11,210. H. L. Haas. Improvements in polishing compositions. Complete Specification. May 22.
 11,328. D. Urquhart and J. M. Small.—From L. H. Despeissis. Improvements in the manufacture of white lead. May 23.
 11,967. T. Turabull. An improved paint or varnish for damp-resisting and other purposes. June 2.
 12,451. E. Cadoret. An improved plastic and incombustible material, textiloid, to be used as a substitute for india-rubber, celluloid, leather, oil cloth, linoleum, mother-of-pearl, tortoise shell, amber, ivory, and the like, and capable of being moulded, drawn, or made into threads, and in the form of plates, tubes, cylinders, or soft or silky threads resembling silk in appearance. June 6.
 12,958. S. S. Hazeland. Improved method of increasing the elasticity of compressed rubber. June 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1896.

8267. E. W. Barnsley. Improvements in varnish and in the mode of manufacturing the same. May 27.
 8706. W. I. Grylls. Furniture polish. June 3.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATIONS.

- 10,752. G. E. Wright and W. Monk. Improvements in the method of and machines for degreasing leather. Complete Specification. May 19.
 11,695. K. Moller. Process for hardening chrome dressed leather. Complete Specification. May 29.
 13,096. T. H. Cobley. Treatment of waste substance for the production of leather board and material suitable for being pressed into form for decorative and other purposes, or for use in substitution for leather floorcloth and the like. June 13.

COMPLETE SPECIFICATION ACCEPTED.

1895.

- 17,402. W. Clarke. See Class IV.

XV.—AGRICULTURE AND MANURES, Etc.

APPLICATIONS.

- 10,715. F. W. Saatmann. Improvements in the manufacture of manures. May 18.
 11,716. F. E. Rutland. An improved fertiliser and insecticide. May 29.

COMPLETE SPECIFICATION ACCEPTED.

1895.

- 12,471. H. Mehner. Method for producing nitrides and ammonia. May 27.

XVI.—SUGARS, STARCHES, GUMS, Etc.**APPLICATIONS.**

11,364. J. D. Scott and A. Smith. Improvements in the purification and decolorisation of sugar liquids and syrups. May 26.

11,790. G. Ranson. Process for the complete refining of sugar. May 30.

11,976. J. Werner. Improvements in machines for mixing syrup. Complete Specification. June 2.

11,977. J. Werner. Improvements in machines for cooling syrups. Complete Specification. June 2.

12,447. A. J. Boulton.—From C. M. Higgins. Improvements in or relating to flour and starch pastes and processes of making the same. Complete Specification. June 6.

COMPLETE SPECIFICATION ACCEPTED.

1895.

13,851. W. R. Hutton. Alkaline saccharates. June 3.

XVII.—BREWING, WINES, SPIRITS, Etc.**APPLICATIONS.**

11,164. A. A. Hollander. An improved method of fining and clarifying beer and other fermented liquors by means of diatomaceous earth. May 22.

11,197. J. E. Lang. Improvements in materials for debasing alcohol. May 22.

COMPLETE SPECIFICATIONS ACCEPTED.

1896.

3098. A. J. Boulton.—From the Pabst Brewing Co. Improvements in or relating to the collection and utilisation of air-free carbonic acid gas from fermentation, and apparatus therefor. May 27.

9740. H. Gronwald. Process for preventing the escape of carbonic acid and other volatile matters from beer in casks. June 17.

XVIII.—FOODS, SANITATION, Etc., AND DISINFECTANTS.**APPLICATIONS.****A.—Foods.**

10,921. F. T. Bond. Improvements in the sterilisation of liquids by heat, and in appliances therefor. May 21.

11,060. J. Davidson. Improvements in the manufacture of products from tea. May 21.

11,637. A. J. Vause. An improved process and apparatus for preserving milk and certain other classes of fresh foods by sterilisation. Complete Specification. May 28.

11,878. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brünig. Manufacture of new albuminous compounds. June 1.

12,094. T. Drewery.—From M. Vander Hagen. A substitute for human milk. June 3.

12,150. F. O. Jacob. An improved process for preserving solid organic alimentary substances. Complete Specification. June 3.

12,283. W. Poole. Poole's improved method for the manufacture of bread. June 5.

12,523. T. F. Garrett and W. M. Spouse. Consolidated soups and vegetable juices. Complete Specification. June 8.

B.—Sanitation.

11,236. S. S. Allin. An improved system of sewer ventilation and of utilisation of town refuse. May 23.

11,243. E. W. T. Jones and J. Garfield. Improvements in the purification of sewage and other liquids. May 23.

11,599. G. T. Gillespy. Improvements in the method of and apparatus for mixing liquids and solutions as in treating and purifying water, impure effluents, sewage, and other liquids. May 28.

12,593. R. Johnston. Improvements in and relating to the disposal of sewage. June 9.

C.—Disinfectants.

11,103. W. S. Duff. The manufacture of an improved solid disinfectant. May 21.

11,557. S. Pitt.—From the Société Anonyme de l'Institut. R. Pictet. Process and apparatus for producing gaseous mixtures, mainly formic aldehyde, for disinfecting purposes. Complete Specification. May 27.

11,716. F. E. Rutland. See Class XV.

12,317. H. H. Perkes. An improved disinfecting or deodorising fluid. June 5.

COMPLETE SPECIFICATIONS ACCEPTED.**A.—Foods.**

1895.

11,613. J. H. Hooker. An improved alimentary liquid. May 27.

15,885. E. Kressel. The manufacture of a new alimentary extract. June 17.

1896.

7894. J. H. Kellogg. An improved alimentary product and process of making the same. June 3.

8152. A. Huber. Process for preserving eggs. June 17.

B.—Sanitation.

1895.

13,857. W. Birch. Improved apparatus for separating solid or semi-solid substances from sludge or other fluid or semi-fluid matters. May 27.

14,727. W. Y. Hardie. Hardie's high pressure blast furnace for destroying towns' refuse and the gases and fumes emitted therefrom, also for preparing and utilising the residuals and by-products for commercial purposes. June 10.

C.—Disinfectants.

1896.

8236. C. H. Higbee. An improved composition or material for destroying insects. May 27.

XIX.—PAPER, PASTEBOARD, Etc.**APPLICATIONS.**

11,961. T. C. Cadogan and The O. S. Kelly Co. Improvements in devices for handling and feeding paper stock. Complete Specification. June 2.

12,682. W. A. Kershaw and The Medway Paper Mills Co., Lim. Improvements in and connected with the manufacture of multiple pulp papers. June 9.

12,693. S. Bennett. See Class V.

COMPLETE SPECIFICATION ACCEPTED.

1895.

15,783. The Kellner Partington Paper Pulp Co., Lim.—From N. Pedersen. Improvements in the method of and means for separating knots and other matters from wood fibre in the manufacture of wood pulp. June 17.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

APPLICATIONS.

10,689. O. Imay.—From The Farbwerke vormals Meister, Lucius, and Brünig. Manufacture of aromatic aldehydes. May 18.

11,961. J. Turner and Co., Ltd., and P. Schidrowitz and O. Rosenheim. Manufacture of derivatives from piperidine tetra-hydro-quinoline, and their homologues. May 21.

11,975. H. Rasch. Process for the production of tartaric acid from wine lees and argols. May 21.

11,166. J. C. Mewburn.—From The Chemische Fabrik von Heyden Gesellschaft mit beschränkter Haftung. A new perfume or odiferous principle and process for the manufacture of the same. Complete Specification. May 22.

11,458. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. The manufacture of pharmaceutical compounds. May 26.

11,538. A. Krefting. An improved method of treating seaweed to obtain valuable products therefrom. Complete Specification. May 27.

12,431. W. P. Thompson.—From Ludwig, Sell, and Co. An improved process for making a compound of good keeping property of salicin, saligenin, glucose, and free hydrochloric acid. June 6.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

13,949. C. D. Abel.—From A. Fischesser and Co. Manufacture of phthalicines by the action of mixed anhydrides. June 10.

14,886. W. L. Wise.—From The Chemische Fabriken vormals Hoffmann and Schotensack. Improvements in the manufacture or production of nitrile of mandelic acid and mandelic acid. June 10.

1896.

8151. J. C. Mewburn.—From The Chemische Fabriken von Heyden Gesellschaft mit beschränkter Haftung. A new product, being pyrocatechin-anhydro mono acetic acid, and a process or processes of manufacturing the same. June 10.

9521. S. S. Bromhead.—From Gretsch and Mayer. Improvements in the process of making artificial musk. June 10.

XXI.—PHOTOGRAPHY.

APPLICATIONS.

11,262. C. E. Elliott. Improvements in connection with artificial light photography. May 23.

11,306. J. Hauff. Improvements in photographic developing solutions. Complete Specification. May 23.

12,615. J. W. McDonough. Improvements in and relating to colour photography. Complete Specification. June 9.

XXII.—EXPLOSIVES, MATCHES, Etc.

APPLICATIONS.

10,703. J. House and A. Gillingham. Improvements in the manufacture of gunpowder and in making up charges. May 18.

11,916. R. H. Courtenay. Improvements in rockets for signalling and other purposes, with pyrotechnic compounds for same. May 21.

11,275. T. Hawkins, J. W. Carr, and A. Wellby. An improved smokeless gunpowder to be used for small arms and projectiles, mining and blasting, &c. May 23.

11,716. S. A. Rosenthal.—From S. J. von Romoeki. Improvements in the manufacture of high explosives from nitro-carbohydrates and nitro-hydrocarbons. May 29.

11,842. G. G. André and C. H. Curtis. Improvements in the manufacture of explosives. June 1.

12,220. J. W. Swan. Improvements in or connected with the manufacture of nitro-cellulose or gun-cotton. June 4.

13,065. A. A. Brown. Improvements in and relating to matches. June 13.

COMPLETE SPECIFICATION ACCEPTED.

1895.

8556. J. D. Kendall. Improvements in or connected with detonators and fuses. June 10.

XXIII.—ANALYTICAL CHEMISTRY.

APPLICATION.

10,627. R. Wells. Improvements in and relating to apparatus for testing butter, margarine, and the like, and in the method of employing such apparatus. May 18.

A collective index, embracing the whole Journal from the Proceedings of the first Annual General Meeting, 1881, to the close of 1895, is now in preparation, and will be ready about the end of the current year. It will contain both a subject-matter and authors' names portion and will be a volume of about 500 pages, uniform in size with the Journal.

The prices will be as follows:—

To Members (see Rules 25 and 27) who make application with remittance not later than September 30, 1896 Each Copy 5s.

To Members (see Rules 25 and 27) who make later application; Libraries, Corporations, and Exchanges on the Society's List, and

Past Members (sec Rule 30).....	Each copy	10s.
To Subscribers	„	12s. 6d.
To others.....	„	15s.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed. The circulation of the Journal is now more than 3,000 per month.

LIST OF MEMBERS ELECTED 15th JULY 1896.

- Downan, Prof. Walker, Ohio University, Athens, Ohio, U.S.A., Professor of Chemistry.
 Crowder, Hedley D., The Lodge, Grove Park, Chiswick, W., Student, R.S.M.
 Dick, Frank B., 39, Queen's Road, Richmond, Surrey, Chemist.
 Foreman, Dr. Chas. A., 59, West 51st Street, New York, U.S.A., Professor of Chemistry.
 Harris, H., c/o Straits Trading Co., Ltd., Pulau Brani, Singapore, Metallurgical Chemist.

PROCEEDINGS OF THE FIFTEENTH ANNUAL MEETING.

PRESIDENT:—THOMAS TYRER.

The Annual General Meeting of the Society was held on Wednesday, 15th July, in the Hall of the Worshipful Company of Carpenters, London Wall, a large number of members being present.

The PRESIDENT took the chair at 10.30 a.m.

The Master of the Carpenters' Company (Mr. EDWARD SMITH), in welcoming the meeting, said that the Company were no strangers to the work in which the Society of Chemical Industry was concerned. They were in the midst of one of the centres of chemical industry, and had an institution of their own at Stratford where they laid themselves out to do some little work for the good of the community. Some years ago, Lord Beaconsfield had stated that an improvement in the value of chemicals indicated an improvement in trade generally. In his then untutored condition the connection between the two things was not

quite clear to him, but he had no doubt it was perfectly understood by the experts before him, and he now began to see that there was much truth and insight in those memorable words. He felt much interest and sympathy in the work of the Society, which in 15 years had opened out a new world of knowledge and progress, and had made a name for future generations to revere. He cordially welcomed the Society to Carpenters' Hall, and hoped that their meeting would be very useful and successful.

The PRESIDENT having thanked Mr. Edward Smith for his kindly welcome.

The GENERAL SECRETARY read the minutes of the last General Meeting, and these, being approved, were signed by the President.

On the motion of Mr. R. Forbes Carpenter, seconded by Mr. D. Herman, Messrs. J. C. Quinn and A. J. Greenaway were appointed scrutators of the ballot for the election of officers.

Mr. E. C. C. STANFORD asked if it were really necessary to go through this form every year, when, as usually happened, there was no contest.

The PRESIDENT replied that while the rules remained as at present it was necessary. It was open to Mr. Stanford, at the proper time, to give notice of amendment in the sense indicated by his question, but in the meantime the rules as they stood must be adhered to.

The GENERAL SECRETARY then read the

REPORT OF COUNCIL.

WE have the honour to report that the number of members on the register is 2,971, as compared with 2,895 at the last Annual Meeting. During the year 237 new members have been elected, as compared with 229 last year; while the loss has been 161, as compared with 160 last year.

During the past session 92 papers have appeared in the Journal, as compared with 85 last year. The excess of revenue over expenditure, as may be seen from the Treasurer's Statement just published, amounted last year to 162*l.* 3*s.*, as compared with 178*l.* 10*s.* 2*d.* the year before. It will be noted that in the statement entrance fees (168*l.*) and life composition fees are placed to capital account, and not to revenue; and the year is debited with 361*l.* 2*s.* spent on the Collective Index. The Publication Committee has given great attention to effecting economies in the production of the Journal, as urged by Dr. T. E. Thorpe in his presidential address last year at Leeds.

The Collective Index is now approaching completion, and will be delivered to members as soon as possible, in two volumes—one containing subject matter and the other authors' names. Arrangements are also already being made to facilitate the production of future Indexes at regular intervals. The number of applications already received for copies at 5*s.* each exceeds 1,400.

The President has visited all the Sections of the Society, including New York, during his year of office, and has in every case been received with the utmost cordiality.

Mr. J. Stanley Muir, late Secretary of the Scottish Section, has accepted an appointment in America, and is succeeded by Mr. Thos. Gray. The following Chairmen of Sections retire this year:—Mr. B. E. R. Newlands, Dr. G. Schack-Sommer, Mr. G. T. France, Mr. C. F. Tetley, and Mr. A. H. Mason. The thanks of the Society are due to them, and the Council hopes to be able to utilise their services in other capacities. The following have been elected to succeed them:—Dr. R. Messel (London), Dr. Chas. A. Kohn (Liverpool), Mr. F. S. Newall (Newcastle), Mr. Thos. Fairley (Yorkshire), and Prof. C. F. Chandler (New York).

The Council has decided to award one of the recently instituted medals at intervals of not less than two years. It is to be given for conspicuous services rendered to applied chemistry by research, discovery, invention, or improvement in processes. The recipient need not be a member of the Society, and may be of any nationality. The first award has been made to Mr. John Glover, inventor of the tower which bears his name, and from which chemical industry has derived enormous benefit. Thanks are due to Sir John Evans and Dr. T. E. Thorpe for their exertions in selecting the design and superintending the production of the medal.

The Society's thanks are due to the members of the various committees, who have so freely given their services to the Journal and other departments, both local and general, of the Society's work. Though the Journal as a rule bears testimony to the work of those engaged upon its production, yet the following instance of otherwise unrecorded work should be mentioned. In August last a sub-committee of the Publication Committee was appointed to consider whether information should be given in the Journal on foreign and colonial chemical patents. Many meetings were held, and, with the assistance of the Editor, trial abstracts of French, German, and United States patents were drafted for the consideration of the Publication Committee. In view of the inherent difficulties of the question and the great cost, the sub-committee had to report unfavourably on the proposal; but the mass of information collected was of such interest that it was ordered to be filed for future use in any enquiries upon the subject.

The proposal to erect a memorial to Pasteur has given the Council an opportunity of testifying its respect towards one who, among the many benefits which he conferred upon his age, rendered great services to industrial chemistry.

Mr. HENRY BRUNSER, in moving the adoption of the Report, said that it appeared to him to be a thoroughly satisfactory one, and he hoped it would commend itself to the meeting.

Mr. F. J. R. CARULLA seconded the motion, which was carried unanimously.

The Hon. Treasurer (Mr. E. RIDER COOK) then formally presented the accounts for the year 1895 (see, *ante*, p. 399). In doing so, he said that just as a nation whose annals were uninteresting was a happy one, so was a society fortunate when its treasurer's report might be taken as read; and that was their position. The published accounts showed a balance of income over expenses of 162*l.* 3*s.*, and that balance would have been larger but for the necessity of providing for the cost of the Collective Index.

Mr. E. C. C. STANFORD moved a hearty vote of thanks to the Hon. Treasurer for his Report and for the great trouble he took in guarding the finances and interests of the Society. He felt sure that those interests were in first-rate hands, and it afforded him the utmost pleasure to move this vote and the adoption of the accounts as published.

Col. D. GAMBLE seconded the motion, which was carried unanimously amid much applause.

PRESIDENT'S ADDRESS.

So much has been recorded about the Society of which, for a brief period longer, I am the official head, especially by my able predecessor, that I do not purpose saying more than that its foundation was fully justified, and the need for its continuance and vigorous sustenance was never greater than at the present time. The report of your Council deals with all necessary points, but I venture to express the opinion that the Council may well consider in what direction the Society's usefulness may be made still more available for the benefit of applied chemistry.

Chambers of Commerce exist in all the large centres of trade and manufacture, and to most, if not all, is attached or affiliated a chemical section or committee. These committees generally have, through their councils, done excellent work in purely trade matters, and in influencing local authorities in regard to river pollution, smoke abatement, and sanitation. Their influence has extended even to Government Departments; and in recent legislation and trade regulation through the Home Office and Board of Trade a restraining and guiding influence has been exerted without, I believe, in any case interfering with the accomplishment of the ends desired by the authorities.

The recent regulations for the safety of workers in works and factories in which chemical operations

are conducted, particularly white lead, bleaching powder, pottery, matches, &c., have been made practical and reasonably free from inconvenience largely by the aid of the committees referred to, and in cases within my knowledge, notably Manchester and London, members of our Society have been most useful in giving practicality to the regulations desired. In London your President, Past Presidents, a Past Chairman and Member of Council, and the Chairman-Elect of the London Section met the Home Office Committee after its conference with alkali manufacturers, and suggested modifications which permitted their application to conditions outside the alkali manufacture. Again, too, a member of your Council and working committees was able to render practical the regulations as to white lead, which otherwise would have been greatly in restraint of trade.

The performance of such beneficial functions relieves our Society from what would otherwise be its imperative duty. Nevertheless, the attention of the Council should ever be directed to the general interests of chemical industry, and its influence maintained as being by no means trivial or insignificant, and as representing, probably, a wider range of interests over a larger area than in any other existing society.

Watchfulness over patent law, trade and merchandise marks, pollution of rivers, noxious vapour, secondary education, endowment of research, &c., is a duty our Council has to some extent performed hitherto, and must, notwithstanding the existence of commercial bodies referred to, continue to perform, chiefly by strengthening the action of these other bodies when possible. In the recent inquiry into the working of the "Sale of Food and Drugs Act," our Society should have had a place. I intend asking the Council to appoint an "Advisory Committee" to watch matters in the general interest.

I think I may venture to give instances of good work done for trade by intelligent pressure brought to bear upon a public department. In 1889, during the time when one of our past presidents, Mr. Howard, was Chairman of the London Chamber of Commerce and I was Chairman of the Chemical Section of that Chamber, it was thought incongruous that British exporters of tinctures and medicinal preparations containing spirit should buy in Germany and export in bond to our colonies. A careful presentation of the matter was made to the excise authorities, with the ultimate result that British manufacturers can now make these spirituous medicinal preparations in the ordinary way with duty-paid spirit, and when exportation is required, give notice to the district supervisor, whose officer inspects the package, takes samples, seals the case, and signs the form. In due course, without locking up the room or premises or needless interference with business, exportation takes place, and in a month or so the manufacturer receives a cheque for the "drawback" or "rebate" at duty rate per proof gallon, with an allowance for waste of 4d., and another 2d. or 4d. as the case may be for additional expense of manufacture, caused by excise regulations, &c.; or because foreign spirit has been used, which bears an extra duty of 4d. per proof gallon as against 10s. duty on British spirit. This drawback amounts to a capital sum returned to British manufacturers by the State. By permission of the Chairman of the Board of Inland Revenue I am enabled to give figures up to the end of 1896 financial year, in tabular form, prepared by the Accountant-General's Department, as below:—

Tinctures—Essences—Perfumed Spirits.

Statement of the number of proof gallons of spirit contained in spirituous preparations exported, and on which "drawback" was allowed in the United Kingdom, in the under-mentioned years:—

Years ended 31st March.	England.	Scotland.	Ireland.	United Kingdom.
	Galls.	Galls.	Galls.	Galls.
1889 (3 mths.)	1,596	1,596
1890.....	3,715	3,715
1891.....	13,012	20	..	13,032
1892.....	20,888	7	..	20,895
1893.....	27,410	23	..	27,433
1894.....	11,662	46	..	11,708
1895.....	38,876	38,876
1896.....	56,963	56,963
Total	209,832	96	..	209,928

Regulations similar to these were extended to the exportation of essences and perfumes, and I can record that the authorities allow bottles so small as $\frac{1}{2}$ oz. to be exported under drawback. This leads me to say that certain very large perfumers have under "lock and key," so to speak, been allowed to work for exportation under drawback. But the concession referred to is for any who take out the 10l. license and thus get duly registered. These are real concessions on the part of a rightly jealous department of the State. I have no doubt that if it were desired to use undenatured alcohol of any strength to a large manufacturing extent, the Department would be prepared to consider the question with an open mind. But we do not grow or obtain in Britain raw material cheap enough for reasonable competition with Germany or Russia. Land is dear, and the agriculturist has not yet acquired the knowledge for scientifically growing potatoes (or, unhappily, anything else), from which most of the foreign spirit is still made. One point, however, deserves notice: the necessity for alcohol as a solvent in the production of fine chemicals is overrated, and in Britain we are practically confined to one form of "denaturing"—viz., 10 per cent. of wood naphtha—which introduces difficulties, and to another—the further addition of mineral naphtha or petroleum, so as to insure "immiscibility" with water. As it is illegal to "clean" methylated spirit, its use is comparatively limited. I do not think any disadvantage would follow if a wider range of denaturing materials was allowed, as in Germany. I am indebted to Mr. Hugo Lorenz, London, for a synopsis of "denaturing" as practised in Germany.

- A mixture of 2 parts wood naphtha and 1 part of pyridine, which is added in the proportion of 3 to 100 litres.
- For the preparation of alkaloids denaturing is permissible by $\frac{1}{2}$ per cent. of oil of turpentine or 0.025 per cent. of animal oil.
- For extraction of jalap and scammony— $\frac{1}{2}$ per cent. of oil of turpentine.
- For polishers, for polish, and if used in their own manufacture— $\frac{1}{2}$ per cent. of oil of turpentine.
- For the production of aniline dyes—0.025 per cent. of animal oil.
- For chloroform, iodoform, sulphuric ether, anti-pyrin from acetic ether, chloral hydrate—0.025 per cent. of animal oil.
- For collodion, tannic acid, salicylic acid, and salicylates—10 per cent. of sulphuric ether.
- For white lead, acetate of lead—0.25 per cent. animal oil.

Such "denatured" spirit is, however, not saleable, but can only be used after "special permission," which has to be applied for by the manufacturers of the respective articles. Any spirit not "denatured," used as an addition to preparations, such as fruit juices, is allowed on "exportation" in full. As regards duties, a quantity of 45 litres pure alcohol per head of population pays 50 marks per 100 litres of 100 per cent. alcohol. Any larger quantity produced has to pay 70 marks per 100 litres of 100 per cent. alcohol. Thus, there are two qualities as regards excise, which are dealt with "On 'Change'" in Germany.

Alcohol is free of duty for exportation, and if used for technical purposes, such as vinegar-making, for medicinal, scientific, heating, cooking, or polishing purposes, illuminating according to special regulations of the "Bundsrath"; such spirit must be worked off in bond, or "denatured" with the admixtures given above, according to the purpose. By the courtesy of Mr. A. Domeier I have been favoured with copies of the German spirit regulations. These I have had translated, and after comparing the regulations as given in Ham's Year Books, Inland Revenue and Customs, for 1896, placed at my disposal by Mr. E. Grant Hooper, of the Excise Laboratory, have concluded that, broadly, we are not hampered materially, and certainly should not be any more so by our own excise department if we produced alcohol at a price which would enable us to compete with German products. Give us cheap alcohol-producing materials, then! At least beetroot and potatoes, which can be as well grown in Britain as in Germany. I have acquired, for the purpose of this and other inquiries relating to the question of competition such an amount of interesting material that when our London Section has nothing better to listen to I may venture a *résumé* thereof.

But it is pleasant to record such "sweet reasonableness" in departments supposed to be specially oblivious to "commercial" interests. I ought to give credit to the Customs department for the concessions made about 1889-90 as regards "denaturing" tea, of which dust and sweepings and low "drinkable" qualities existed, which because of exigencies of revenue were not available for manufacturers' use. Members of our Society through the Chamber of Commerce obtained these sensible departures in the interests primarily of British manufacturers.

A further instance of "reasonableness" is that the House of Commons, after a short debate, but without a division, adopted the following Government motion:—"That the duty of Customs now payable on cocoa or chocolate, ground, prepared, or in any way manufactured, under the provisions of the Act 42 & 43 Vict. c. 21, s. 3, shall be payable on that product of the cocoa-bean which is generally known as cocoa-butter." As the House of Lords no longer interferes with questions of Ways and Means, the adopted motion has now the force of law, and accordingly a duty of 2*d.* per lb., equal to about 15 per cent. *ad valorem*, will now be levied on cocoa-butter, as it as long been on imported ground, prepared or manufactured cocoa, while the raw cocoa-beans used by British cocoa manufacturers will pay, as heretofore, a duty of 1*d.* per lb.

In Germany there exists a Society for the Protection of the Interests of Chemical Industry. Its functions seem to be a combination of our objects and trade protection. It usefully influences the Government, and has secured for chemical industry an amount of consideration by the State unknown before its existence and quite unknown here. Its statistical reports are abstracted in foreign and

English journals, and the Trade Report of our own Journal has given from time to time such necessary figures as would suggest reference by those interested to the official sources.

There are regulations for factories of soap, explosives, powder, guns or caps, nitroglycerin, fireworks, manure, sulphuric acid, and for cleaning out Gay-Lussac towers, &c., in its official circular.

The decisions of its council are binding upon the members, and the regulations made in co-operation with Trade Associations for control of workmen and technical operations are accepted by State Departments, and in matters relating to accidents, fire, &c., by the insurance companies. Such matters as buildings and internal arrangements, lighting, machinery and gearing, apparatus for working under pressure, elevators, tackle, protective apparatus, as goggles, masks, respirators, and clothing, medical superintendence, date of enforcement, penalties varied suitably for the various manufactures or workers affected, according to the risks, are governed by the society I now refer to. These functions are in some measure effected by our own Home Office and Local Government Board, watched by the Chambers of Commerce and interested bodies. Our Society could and should do something to amend the crude and unscientific classifications of both insurance and railway companies.

A peculiarity of membership is the mode of contribution, which, I fear, would not find favour in Britain. Section 8 of its constitution says: "Every ordinary member shall pay an entrance fee of 20 marks and an annual subscription, the latter in proportion to his 'salary' as manifested in the official statistics relating to accident insurances. The minimum subscription for all 'salaries' up to 20,000 marks shall be 25 marks, beyond that as follows:—

Salary.	Subscription.
Marks.	Marks.
20,000—25,000	25
100,000—200,000	100
200,000—500,000	150
500,000—1,000,000	200
1,000,000—5,000,000	300
5,000,000—750,000	400
Above 750,000	500

"Where there are several ordinary members from one factory, only one is called on to pay the higher subscription corresponding to his 'salary,' the others, as private members, only paying 25 marks."

I think this arrangement would not accord with British notions of a subscription, but the important fact to be noted is the "pulling together" which characterises German technologists, and thus powerfully influences those corporate bodies which may affect trade interests.

Its rules, &c., as made or modified, are duly and officially published after approval by the State Insurance Board. The penalties go to the sick and pension fund. The amount is decided by the Council, by the managers of the sick club, and, failing them, by the police authorities.

I presume it is a matter for congratulation that the scare of three years ago, as to the diseases caused by trades, was found to have little foundation in fact.

Men were not dissolved wholesale in caustic pots, nor boiled in mash tuns or boiling coppers; nor did they fall in alarming numbers into molten metal. Neither did white lead decimate the Tyne, Sheffield, Hull, or even London. Nor did free chlorine or sulphuretted hydrogen in Widnes or elsewhere materially add to the mortality of the locality of the

"White Slaves of England" as a writer, R. H. Sherard, in the current number of Pearson's Magazine suggests. Yet, be it admitted, regulations were rightly called for, if only for the mutual encouragement and protection of the unselfish manufacturer and dependent worker. Incidentally one should remark that the greatest mortality was among the young, due in part to defective food and sanitation, and to hereditary weakness, arising from the too prevalent "drinking" habits of workers. You are well aware that State regulations, as we experience them, have not ruined any industry, nor inflicted more than the most temporary inconvenience or hardship. We have doubtless all heard from time to time how hardly rules and regulations, State or municipal, press upon chemical manufacturers, and the impression exists that the British manufacturer is severely handicapped as compared with his foreign competitor. Our London member, Mr. Oscar Guttman, was so good as to place at my disposal two German books, which proved so interesting that I had them translated by Mr. Chas. Salter and Herr Gustav Naumann.

One is entitled, "The Risks run by Workers in Chemical Manufactures, Protective Measures against Accidents, and Conditions of Labour: A Critical Review of English and German Industrial Conditions, inspired by the English Parliamentary Report, 1893. By Dr. Konrad W. Jurisch, Royal Technical High School, Berlin." The other, "The Factory Acts of Germany; The Licensing of Industrial Concerns in Prussia: A Collection of all the Laws of the Imperial Diet and Prussian Ministerial Decrees and Instructions for Technical Guidance, besides Examples of License Applications and Documents." By Dr. von Rüdiger, Industrial Councillor of the Kingdom of Prussia. I may, prior to considering Dr. Jurisch's book, refer to that of Dr. von Rüdiger.

There are general regulations, and special rules for every industry. Besides those named as purely chemical or allied are, yeast, dye, furriers, tanners, hide strippers, bakeries, mills, aniline, horn, animal oil works, &c. Every condition of security against ill-judged locality, effluvia, and subterranean contamination is defined, and must be carried out to the satisfaction of the police, with power of appeal to the courts. Every piece of apparatus must be provided with protective gearing appliances for safety, such as gauges, manometers, thermometers, &c. Every vessel subjected to pressure, however low, must be certified as having been tested by competent persons. For defects, fines are instituted, and workmen are also involved. They must, subject to fine or summary dismissal, give notice of defects and flaws, and must themselves be co-workers with the authorities. Now, to what serious and interfering extent does any of the State or local control existing to-day in Britain affect any industry? I have compared the regulations for machinery, noxious gases, aniline, white lead, alkali, glass, and general factory rules, and find what would almost lead to a revolution in this country. British industry cannot honestly complain, in comparison of being overdone as yet by interference of this kind.

The defect of English local supervision is the variations in the rules of contiguous local authorities. In London, especially in the east, the building and other regulations of the County Council differ from, and in some cases are opposed to, those of the borough authorities. Sheds or erections which by the latter would be permissible are absolutely refused by the former. An instance occurred in London recently, where, in consequence of the totally unnecessary demand for substantial brick walls, the whole foundations had to be "piled," and there is a forest

buried. No considerations of fire or weight existed in four-fifths of the structure. So as to smoke: in some districts one must scarcely dim the azure sky, but in others one can "go ahead." I do not here discuss which is the better condition of the two economically, but, to say the least, we have, in the matter of economy of fuel, much to learn. This week I have been asked to bring the influence of the Chamber of Commerce, through its Chemical Committee, to bear upon an Act of Parliament—57 & 58 Vict., chapter cciii.—The London Building Act. It is a consolidating Act, but it regulates fees payable to surveyors, among which is 10s. for superintending the erection of every oven, copper, steam boiler, or stove to be used for trade purposes, and not heated by gas. For superintending the fixing of pipes for conveying heated air, water, or steam at high pressure (for each floor of a building in which pipes are fixed), 10s. A manufacturing firm in the colour industry in London complains of such a regulation and fee as unjust, and fairly so. But the regulation itself for security is mild compared with Germany. One difference in favour of Germany exists, however. When the manufacturer is permitted to fit up works he can start, and his license once passed he is safe from constant intrusion and vexatious interference from either neighbours or municipalities.

Broadly speaking, German regulations are far more stringent in every respect, constructional and hygienic, and in no sense are they favourable to German competition with England.

I assume most manufacturing chemists are cognisant of the general contents and conclusion of that British report, 1893, resulting, as I have said, in certain Home Office rules. Eighty pages of deeply interesting excerpts from the English report—perusal of which I commend to the writer in Pearson's *afore-said*—are given in Dr. Jurisch's review. These cover the terms of reference to the Home Office Committee. Dr. Jurisch observes; "Such alterations as would deeply affect the interests of capital and the voluntary action of individuals could only be indicated *as d'sirable*; on the other hand, the adoption of simple precautions having no effect on the manufacture itself could be strongly recommended." "With this," he observes, "every manufacturer would at once agree." "The investigations of the committee are of great technical interest, giving as they do an authoritative report on the actual conditions of English chemical industries." "German industries, notwithstanding variations in the conditions of manufacture, derive benefit therefrom, especially where hygienic and social questions are involved." As you are aware, the British committee was occupied specially with those branches of industry wherein the respiratory organs of the workers were subject to the influence of noxious vapours. Also with those wherein accidents may occur from contact with caustic substances. Industries of necessity involving special precautions were not referred to that committee, since they—for example, the manufactures of arsenic acid, arseniates, artificial manure, cement, explosives—were already more or less regulated. It is pleasing to observe in Dr. Jurisch's work the names of prominent members of our Society, and as pioneers among improvements Past Presidents and officers thereof. I would simply observe that Dr. Jurisch, who himself had experience in English works, makes very interesting comparisons between English and German methods of working, especially in alkali branches. He criticises the obstinacy and perverseness of the British workman in no measured terms—exemplifying this by his refusal to use mufflers or respirators or the "smoke" helmet, even in "bleach" works. I am

afraid most of us have found his independence a vexatious matter. It is evident that the manager of a chemical works, who has to aim at the production of first-class qualitative, quantitative, and economic results, can only devote a fraction of his attention to enforcing regulations of the character referred to. When every appliance and precaution have been provided, more must be left to the intelligence and common sense of the worker. It was a good thing, and without precedent, by the recent English Home Office rules, that in cases of wilful neglect the offending workman became liable to a fine. It may not be without interest to observe that the reduction of hours of labour, notably the introduction in certain chemical industries of the three shifts of eight hours each, has in most cases produced better results than the old. As much money was earned, for better work, with increased interest and care by the workers, and with decided benefit to them physically, as fully proved by the figures given in the report referred to.

Forty-nine pages are devoted by the author to German industries, and it goes almost without saying that the range of regulated industries is greater than in Britain. Considerable divergencies exist between the industries of the two countries, due to the influence of historical, technical, and capital development, geographical and social conditions, and the characteristics of the people. English works are arranged generally for the production of a few articles, and in most industrial and crowded centres, situated closely together, as at Widnes, St. Helens, Newcastle, Glasgow, Birmingham, Manchester, and London, which latter is probably the largest manufacturing place in Britain, including as it does a very considerable number of chemical manufactures which could be classified under our Journal headings. As a consequence, the conditions of labour are fairly uniform.

Dr. Jurisch comments upon the absence of secrecy which results from this proximity of works. He observes that "factories thrive by the proper adjustment of purchase and sale contracts, intelligent management, and prompt application of every improvement brought to notice in such open interchange of experiences." He remarks "that this openness is of great value to the industry as a whole, since the most enterprising may expose themselves to the risk of placing important intellectual and scientific labour at the disposal of less endowed competitors, but they increase their own reputation, influence, and consequently 'pecuniary' position." I am afraid the Doctor's admiration for our "insular" generosity has carried him beyond the limits of agreement with him. Only lately, in a presidential visit to a northern industrial centre, the Chairman of that Section observed to me "that most of the good things had been learned here, and imitated and even improved upon abroad, as a consequence of the generous practice of permitting scientific technologists to inspect, visit, and even work in English works." This quite unnecessary liberality is being discontinued, and not a day too soon. One of the advantages Dr. Jurisch claims for this aggregation of factories is that individual "noxiousness" is lost in the general mass. Herein I think he is wrong, unless inspections under the Alkali and other Acts are a dead letter. Writing of the recently issued 32nd Annual Report of the Chief Inspector under the Alkali Works Regulation Acts, the "Chemical Trade Journal" rightly observes: "It will be seen that in every manufacture the management must ever be in a state of ceaseless activity, and that the public is now protected as it never was before. The report shows how much useful work can be done by a

central authority under which everyone inspected is treated alike. In this respect it contrasts very favourably with the methods employed for the suppression of other nuisances, looked after and inspected by local authorities, every one of which has a code differing from that of its neighbour, and endeavours to ameliorate the conditions by a series of petty prosecutions rather than by the appointment of men who understand their business to see that progress is made in the right direction and at as little cost as possible."

In Germany the factories are widely scattered, from East Prussia and Upper Silesia to the Rhineland and Alsace, from the Bavarian Alps to Bremen, Hamburg, and Stettin. In only a few districts are the factories close together—Upper Silesia, Stassfurt, Elberfeld, Frankfurt-on-Maine, and Mannheim. As most of the German factories were developed from small beginnings, generally for supplying local requirements, they produced a number of articles. One consequence is that processes are not divulged as in Britain. The patent laws have probably had great influence, being stricter in the requirement of novelty than ours, in enforcing secrecy as a means of self-preservation. I may mention it is stated that 25,000 patents are taken annually in America, 13,000 in Germany, and 1,000 in England. Also, that such divergence of opinion exists as to the best Patent Law that our Council has been unable to formulate satisfactory amendments therein. I think the disadvantages of our insular method outweigh those of the secretive method. We may trust to the spread of intelligence, more skilled supervision, and greater scientific management to neutralise the defect of the German system as described by Dr. Jurisch. If my reading is reliable, my inference is the other way, and indeed the present condition of German chemical industry proves it to be so.

"The secretive method produces a dislike to inquiry and interference." But the German manufacturer has enough of it arising from the socio-political legislation so characteristic of that country. There, State regulation prevails in everything. Every manufacturer has to give particulars of rates of wages and hours of labour. Benefit clubs supply complete hygienic statistics; every accident (and rightly) has to be reported. Yet the necessarily voluminous materials so statistically treated, *not* primarily intended for publication, are nevertheless published. "One result of the secretive method is not only the subdivision of factories in Germany, which places difficulties in the way of men changing employments, but has created a different relation between employer and employed." The British workman, even when unable to read or write, has a decided sense of independence which affects materially his daily relations. Oppositely, the German workman, always able to read and write, and altogether better as regards elementary education, is obedient, as a result of military service, to regulations and directions by his superiors, unless spoiled by the social democratic agitator. The relation therefore is more personal; the employer knows more of his workers, and his interest is served by himself instituting social improvements without waiting for legislative compulsion. Nevertheless, German manufacturers *must* promote and institute these benefit societies, which are uniformly regulated by the State through the trade associations. One result of their method is that the more deliberate and careful performance of operations conduces to their efficiency as well as to the greater safety of the workmen. And while the British report of 1893 shows that the accidents and mortality were not greater in chemical factories than in other occupations, the statistics

in Germany show a less proportion of accidents, sickness, and death than in similar occupations in England. The statistics of the two countries are not comparable, being based on different systems; but a perusal of Jurisch's report is very interesting. I give later on one or two from the industries most nearly approaching ours. Most exhaustive reports appear for Germany in Albrecht's "Handbook of Practical Industrial Hygiene," Berlin, 1894; Th. Weyl's "Handbook of Hygiene," Jena; and in the Reports of the Trade Associations of Germany. In these days, when every political party (there used to be only two) bids for the vote of the masses, and social legislation is a matter at least of copious "promises," it may not be amiss to note that the social legislation of the German Empire practically dates from 1883, when the Emperor William I. and Prince Bismarck, with the concurrence of the executive and the Reichstag, instituted laws for insurance against sickness, 1883 to 1886. In 1884 to 1889 was instituted accident insurance. In 1889, Frederick William II. provided the old age and disablement insurance. 1891 saw provisions regulating hours of labour and the employment of women and children. In 1894, prohibitions as to Sunday labour were made (Chemische Industrie, 1894, p. 487; 1895, p. 123). In June 1894 the Eighth Assembly of German Trades Associations in Dresden was satisfied with the social legislation, and appreciated the good influence of the same in pacifying workpeople and producing better relations. The German Society for the Protection of Chemical Industry had drawn up special rules and regulations in conformity with the laws for use in works belonging to its members. The Commissioners of this powerful association and the official factory inspectors travel about and act in concert, and, where necessary, new rules are made and adopted by the trade associations without delay. A valuable report on this matter will be found in the Chemische Industrie, 1894, pp. 269-303; 1895, p. 26. One result is that factory hygiene is in an advanced state, and the percentage of sickness and death much lower than in Britain. I fear the British workman will not take kindly to the system of minute regulations. He thinks he has sense and expects an employer to trust to it. My experience is that, in chemical works at least, one would rather have the sense and a little more obedience. "Oh! leave it to me" is a phrase too often heard at home. Definite results can only be attained by definite means, and this is more likely to result, as indeed it does, when workers, especially officials, are accustomed to obedience. It is convenient to let some do the thinking and let others simply obey orders. Nevertheless, the opinion is steadily gaining ground everywhere that long hours of labour, formerly 12 and 14 per day, now 10 to 12, are subversive of much of the good intended in social legislation. As a consequence the labour rate is proportionately higher, being the same and gradually increasing for the shorter hours. The change here is and must be gradual, since, if shorter hours means higher wages *pro rata*, competition becomes one-sided. There must be time for the introduction of mechanical and other economies tending to equalise commercial conditions.

Thus, equalising forces are everywhere at work which may more speedily than some imagine make the difference in conditions in England and on the Continent less acute than now. Dr. Jurisch observes "that these long hours prevailed among all ranks of assistants—educated or not—until quite recently, and from his own experience points out the destructive effects of such hours upon the "scientific imagination," the tendency being to cripple the intellectual

faculties, through an unnecessary condition of bodily fatigue, practically for the sake of having a condition of military discipline"; and he ventures the remark, "that the habit of whiling away time during the course of the long days of labour, as a consequence of this fatigue, constitutes a 'veritable cancer' in German industries." This will be news to most of us. He quotes the experience of Messrs. Brunner, Mond, and Co. to show the beneficial effect of shorter hours and more continuous and methodical work in making the cost of labour per ton the same with short as long hours. It must be admitted that the conditions of great industries, like soda, iron-smelting, glass, milling works and others, offer special facilities for short shifts. "One chemical manufacturing firm (sulphuric acid) in North Germany sought to impose the following terms on a *chemist* who applied for a situation in 1895. Working hours: daily, 7 to 7; Sunday, 8 to 12. Salary, 1,800 marks (90*l.*), with free lodgings, at a distance from the nearest large town; the engagement to last five years."

It is conceded by all the authorities that I have been able to consult, that in laborious work the British workman has no superior; nor certainly, when he is a man of temperate habits, is he less reliable than the German similarly engaged. But the fact remains that statements in the newspapers and certain magazines have unfortunately a considerable and somewhat humiliating amount of truth.

Personally I prefer the shorter hours, if fitness to employ them fully were gained by a sensible utilisation of the second eight hours in decent recreation or useful occupation for personal improvement. One hopes for an increase in the rational employment of the portion of time free from the obligation of labour. Among these is the use of the evening "continuation school"; but my own observation and official reports go to show that the working classes as a rule do not utilise the privilege. The evils are, that there is no "obligation" to attend, as in the day schools, and the "classes" are chiefly recreative. There is no fear of our doing too little in "recreation." An American professor present, who has crossed the Atlantic many times, observed to me that the change in the matter of recreation and amusement in London was marvellous.

At Meister, Lucius, and Brünning's colour works at Höchst, 6 to 5 are the hours, with the usual half-hour and hour for meals. In those branches where work is continuous the hours are from 6 to 6, 10 per cent. extra being paid for overtime. In addition now to Sundays, the great Church festivals are holidays, and men are given time to record their votes at elections. The technical director is no hard-and-fast 12-hours' man, neither is he blindly in favour of eight hours, and he gives excellent reasons for flexibility in this matter. For the averages in England I refer you to the 1893 report before referred to, but Grandhomme found that the daily wages at the Höchst works ranged from 0.50 to 6 marks (6*d.* to 6*s.*). At the end of 1893, 2,626 workmen were engaged, and the average daily wage per man amounted to 2.86 marks, made up thus:—

Rate per Diem.	No. of Workers.	Percentage of Total.
Marks.		Per Cent.
0.50 to 1.00	34	1.29
1.00 " 1.50	63	2.40
1.50 " 2.00	114	5.48
2.00 " 2.50	372	14.20
2.50 " 3.00	1,136	43.25
3.00 " 3.50	455	17.32
3.50 " 4.00	311	11.84
4.00 " 4.50	99	3.77
4.50 " 5.00	12	0.45
Total.....	2,626	100.00

In addition, premiums are paid by the firm, amounting in 1892 to 22,312 marks among 2,304 workers, making the average earnings per man 1,000 marks 50'1.

Mean Values of Sickness for the Several Departments.

Weekly wages, Mks. and pf.	18'50	22'50		{ Furnace-men 22'00 Vat-men 24'34 Salters 17'50 Finishers ... 17'50		21'70		28'0

Mortality and Sickness in 1893.

	Vitriol and Salt-cake.	Bleach.	Soda.	Mechanical Department, Cuopage.	Total.
Number of members in Sick Club.....	71	45	54	156	324
Days of sickness.....	1,227	592	229	1,394	3,715
Deaths.....	1	1	2
Average number of days of sickness per member per annum.....	16'4	11'1	5'4	11'3	11'5
Number of deaths per 1,000 per annum.....	13'3	6'6	6'17

Of these workmen, 12·03 per cent. were over 40 years of age.

In the Chemische Fabrik Kalk according to a personal communication the following figures were obtained:—

Year.	Number of Workers.			Days of Sickness.		Deaths.	
	Total.	Between 14—16 Years of Age.	Between 16—21 Years of Age.	Total.	Per Head.	Total.	Per 1,000 Workers.
1891	544	15	39	5,014	11·06	4	7·35
1892	551	15	46	6,871	12·47	6	10·89
1893	572	17	54	6	10·49

The subjoined table, privately communicated, gives particulars of wages at the Chemische Fabrik Kalk, Besch:—

Year.	Number of Workmen.	Total Wages paid per Annum.	Average per Head per Annum.
1891	544	Mks. 546,583	Mks. 1,005
1892	551	542,109	984
1893	572	561,719	982

For convenience, it may be well to give a few British figures for comparison from the report for 1893:—

TYNE AND SCOTLAND DISTRICT.

The "Foresters" sick fund statistics led to an inquiry, and Mr. T. W. Stuart, a past chairman of our Newcastle Section—from a comparison of what are known as Finlaison's figures and those of his firm, Messrs. Chas. Tennant and Co., Hebburn—drew the following:—

First.—The average number of days' sickness per annum per man at the above works was 10.37 days, which is practically the average sickness amongst the working classes of this country, as shown by the returns of friendly societies; whilst the number of days' sickness amongst the men employed in the vitriol, salt-cake, and bleaching-powder departments, was 23 per cent less than this, or only 7.88 days per annum per man.

Secondly.—The annual rate of mortality for the whole society averaged 11.42 per 1,000, and amongst the men in the vitriol, salt-cake, and bleaching-powder departments 12.19 per 1,000, whilst the average rate of mortality experienced by friendly societies is about 12.80 per 1,000.

Finally.—Judging from the figures given, it would appear that in these works—and by analogy in all works where the same operations are carried on: (1) The rate of mortality throughout the works, and in the three departments where gaseous escapes are liable to take place, is slightly less than the average experience of friendly societies; and (2) the number of days' sickness per annum per man in the whole works is about the same as the average of friendly societies, whilst the sickness in the three departments where gaseous escapes are liable to take place is actually about 23 per cent less than the average of the working classes of this country.

The Oldenburger Glashütte paid in 1893, in round numbers, 570,000 marks in wages to 570 men, or an average of 1,000 marks per annum. One at once sees that the price of labour gives advantage to this industry. But the most unsatisfactory and the really deterrent influences in Britain adversely affecting the glass industry is the protective system abroad and, as regards bottles, the influence of the trade unions. It is impossible to get a smooth, even-surfaced, and well blown or moulded bottle for fine chemicals, which in appearance are marred when made and put up by English manufacturers in English glass.

Twenty years ago Britain was the largest producer of plate-glass; then followed France, Belgium, and Germany. Now, mainly in consequence of the action of protective tariffs, the position is reversed, and England takes the last place, the first being taken by the United States of America, followed by Belgium, France, with Germany about equal to England. (See Table III.)

Now, the conclusion I arrive at is that the real cause of the progress and prosperity of German chemical industries in particular is to be found in the superior qualifications of her directing mind. If the workman is more rather than less of a well-drilled machine, then his labour is obviously

more intelligently directed. Enterprises in Britain will occur to you, and in every case their successful continuance and competition is due to the intellectual calibre of the technical directors. I saw it stated in a trade organ the other day that the true reason for the large dividends paid by a well-known "Ammonia-Soda" Company was the possession of "combination" patents and agreements with foreign makers of the same article. This may be true in part, but the chief reason is superior skill, knowledge, and "common sense," and ability in the directing and controlling staff. Germany does not owe her progress alone to protective tariffs; nor to "port bounties," as on sugar, thus crippling—yea, ruining—a great British industry; nor to the superior discipline of her workmen; nor largely to the difference in wages in the great industries; but to her thorough system of education, elementary and secondary.

I quote, by the way, as regards Hungary, from a private correspondent:—

"The Government does all it can to promote industry, and especially chemical industry. It halves the railway rates and gives a free plot of ground to build the 'Fabrik' on, and for five years one is exempt from taxes on chemicals, &c. that are used in the manufacture. It also guarantees to take so much of whatever article (soap, matches, soda, &c.) is manufactured off one's hands at its own risk. Native labour here is also cheap: from 10/-—2s. per day of 12 hours."

In "Nature," 30th April 1896, page 602, occurs this passage: "Virchow visited England four or five years ago, and on his return to Berlin, he reported: 'England is a century before us in sanitation, and a century behind us in education.' This is overstated, but there is too large an element of truth therein nevertheless."

The president of the meeting of Trade Protection Societies lately held at the Westminster Palace Hotel had some unpleasant things to say, and said them. They were none the less unpleasant because they were not new; but I do not accept his pessimistic view to this extent: "Our agriculture is going to the dogs; our iron trade is following it; and what we lose in this branch Germany and Belgium gain." It should be noted that Consul Landenberg, in a recent Foreign Office report, complains bitterly of the state of agriculture in Germany. Also, the 32nd report of the Chief Inspector under the Alkali Act quotes figures as to British manurial products which modify somewhat the colour of the above statement (see this Journal, Class VII., page 541). The tale is told at greater length in the series of remarkable articles contributed to "The New Review," and just published in book form by Heinemann. It is Germany, Germany all through. It says: "Germany is especially beating us in the chemical trade, which Lord Beaconsfield, in what turns out to have been an inspired moment, described as the test of a nation's prosperity. The causes are as clear as the evil. The Germans have more knowledge, and they take more pains, while all our difficulties are evidently of our own making, and would find no panacea in protection. The English drug trade cannot endure the high dock charges of the port of London. We have lost our 'push.' And why? Simply because their chemists are 'ever devising new preparations.'"

High chemistry means "high development"; and it would be well to refer to a paper in our Journal by Dr. H. E. Armstrong (this Journal, 1887, 482—490) on Synthetic Chemistry. We shall all be glad if, even at this distance of time, the worthy professor completes the paper up to date. I make this

suggestion to his intimate friend, Dr. Messel, Chairman-Elect of the London Section.

Protection as a national policy would be a poor remedy, and probably a short way to ruin.

To those to whom Protection is a "hogey," I recommend regarding it as "diaphanous." To those to whom Free Trade is a kind of "fetish," I remind them, we have "free importation," which is not free trade, and in any case "cheapness" for the masses. Possibly there are evils in both, but neither are useful without education.

I refer those interested to the reports of the Science and Art and Education Departments, to the reports of the County Councils, the City and Guilds of London Institute, to the reports of the Board of Technical Education, and to the recent report of the Royal Commission on Secondary Education (1895), to which, by the way, I have referred in my remarks at two of the Sections visited during my year of office. Those remarks may be summed up, in my opinion—(I sincerely hope I may be quite wrong, and shall be delighted to be proved so)—by the phrase "How not to do it."

We will not take pains, and our rivals will. This is the great truth to bear in mind. The danger is that we should be turned aside from the true causes of all these evils and the true remedies for them, as we have already been turned in the case of agriculture.

I may and ought perhaps to note, from a business point of view, that our commercial education, better now than it was—thanks very largely to the Chambers of Commerce, and not least to that of London—is very far from being an effective instrument for "pushing" business. How few know two languages. How few also know anything of commercial geography. Here are some figures from a recent trade journal. It says: "When we have been travelling abroad nothing has struck us so much as the number of German and other continental travellers which are to be met with in every quarter of the globe. English manufacturers have little conception how frequent are the complaints of British consuls abroad that, while other nations employ commercial travellers systematically and in large numbers to push trade, British manufacturers do not. In Switzerland, where a system of licensing commercial travellers exists, comparative statistics have been made accessible, and those for 1894 are published in a recent report by Mr. Herbert, of the British legation in Berne. In 1894, 18,653 permits were issued to commercial travellers, of whom 11,184 were Swiss and 4,469 foreigners. The latter were distributed as follows:—Germans, 3,310; French, 653; Italians, 175; Austrians, 154; Belgian, 70; British, 69; various, 38. On these figures Mr. Herbert remarks that they show the activity of the German trader, and the statistics of the foreign trade of the country, which he gives elsewhere in his report, show that by far the largest share of the imports and exports of Switzerland falls to Germany. Of imports, amounting in value to over 33 millions sterling, Germany sends 29.4 per cent., followed in order by Italy with 17.41, France with 13.35, Austria with 9.72, and Great Britain with 5.22 per cent. The exports amount to nearly 25 millions sterling, of which Germany takes 25 per cent.; Great Britain, 18.93; France, 11.75; the United States, 11.56; Austria, 6.33; and Italy, 6.11 per cent. respectively. It should be added that German trade increased in 1894 in consequence of the Swiss tariff war with France; but the commanding position of Germany in the foreign trade of the Confederation must be in part due to the

3,300 commercial travellers who annually seek to increase it."

There is no doubt we are paying the price of a long, deserved monopoly; our traders have to some extent waxed fat, and do not work so hard as they might. They will wake up soon, when they see where they have got to; and technical schools in England, affiliated to the Universities, as in Germany, will help to keep the traders up to the mark.

I venture to think we have arrived at a critical period in our industrial life. There is, too, a great and increasing dependence upon the function of the State. "Individualism" has hitherto characterised British life, just as now "Industrialism" is characteristic of everything German that is not military. The State executive feels this, and—under the influence of what should be well-considered opinion, but is not—"finkers" with educational and social legislation, handing over to bodies, local, municipal, county, and sectarian, matters of Imperial concern. In a recent discourse Professor Roberts Austen contrasted the readiness with which our Government obtained 18 millions of money on additional armaments, and spent 4,000*l.* only on the endowment of research.

It was reserved for our Honorary Foreign Secretary to devote a magnificent sum to the purchase and equipment of the Davy-Paraday Research Laboratory now attached to the Royal Institution, and equipped, let me say, with the finest "tools," so to speak, obtainable in the world—and so set a brilliant example of unselfish liberality, which, it may be hoped, will in obvious directions be followed by others who, like him, have achieved well-deserved success. As you know, Dr. Mond contributed handsomely to the "Schorlenner" Laboratory in Manchester, said to be the only specially organic laboratory in England. Happy is it in being presided over by the son of our Past President, Dr. W. H. Perkin, F.R.S.

Wherever I went in America evidences of the liberality of successful men were manifest. In Boston, with the noblest public free library in the world, the Massachusetts Technical Institute stands prominent as a finely appointed and equipped institution. In Baltimore the Johns-Hopkins Schools and Hospital boldly point the truth of the blessedness of giving. The Lehigh Valley University is a splendid testimony to foresight, and feeds to-day a district full of magnificent industries and possibilities. It was the sight of one of these—the Bethlehem Iron and Steel Company,—with its overwhelming appliances, and its completed turrets and guns for the United States Government, and its partially constructed ones for that of Russia, that impelled me, on returning to my hotel at night, on reading the telegrams from Britain announcing the strikes on the Clyde and at Belfast, to write a warning and protest to the British press for the benefit of the leaders. No good resulted, so far as I know, and so long as warnings like these, and object lessons such as the newspapers and articles before referred to, go unheeded, so long shall we remain commercially unprogressive. To me it is equally reprehensible whether our educationalists or our leaders of thought or of industry are wrapped in the thick mantle of national conceit. Professor Chandler, who has been elected Chairman of the New York Section of our Society in succession to Mr. A. H. Mason, personally well known to so many in Britain, and Professor Doremus and other American citizens are with us; and I take this opportunity of publicly thanking the New York Section and the members of the American Chemical Society—whose editor, Dr. Hart, of Lafayette College, made your acquaintance last year when over here—for the generous welcome

and hospitality accorded to your President and Honorary Foreign Secretary last year, and I thank our American members for their presence here to-day.

In the United States, educational institutions are divided into two categories—those supported from public funds and those endowed by private liberality.

This applies to schools, high schools, academies, colleges, and universities. In some instances the foundations are of a mixed character.

New York City possesses an extensive system of free schools, and two colleges—one for young men, the other for young women, while the construction of high schools is now being planned.

The college for young men was established in 1817 by a vote of the citizens. Any young man may acquire collegiate training leading to the degrees of A.B. and A.M., or to the degrees of B.S. and M.S. In the latter case, he may pursue one of two courses, in one of which mechanical arts predominate. The study of sciences forms an important part of the curriculum. No student is exempted from the work. It was the only collegiate institution in New York City for many years that insisted on the performance of laboratory work in both physics and chemistry.

Before 1850 no opportunity existed in New York for students to acquire instruction in chemistry by a laboratory practice. Though Torrey, John W. Draver, and Wolcott Gibbs were doing admirable work, they were all hampered by a lack of facilities. The first working laboratory for students was that of the New York Medical College. Here medical students were instructed, and with them the students of the College of Pharmacy, at that time without any laboratory or lecture-room facilities. Special students also received instruction. The establishment of this laboratory was due to the efforts of Professor R. Ogden Doremus, who had been the sole pupil and assistant of Professor John W. Draver for many years. The construction of this laboratory was followed by the establishment of one at the Long Island Medical College in Brooklyn, the Bellevue Hospital Medical College of New York, and the College of the City of New York, with each of which institutions Professor Doremus has been connected.

The latter college is about to secure more commodious quarters, and plans are being drawn for building to accommodate 3,000 students. These buildings will contain thoroughly equipped physical and chemical laboratories. Instruction in these will be imparted to advanced classes, while the youngest class will, as heretofore, have the opportunity of listening to lectures, copiously illustrated by the aid of the best apparatus.

Besides this distinctly free institution, there are several others, some much older, some younger. They owe their existence in a large measure to private munificence, which in two instances has been very lavish of late years.

King's College, now Columbia University, has just laid the corner stones of several magnificent structures, the chief of which—the library building—is the gift of the able and eloquent President, Dr. Seth Low, one of the finest orators in America, and will cost 1,000,000 dols. (250,000*l.*). The physical and chemical departments are to be equipped on the most extensive scale. In these, advanced courses will be given in both scientific and technical education. Beginning in the smallest way as the School of Mines, the chemical department has, under the untiring efforts of Professor C. F. Chandler, been raised to the importance it merits. The donation of 500,000

dols. for a chemical building by Mr. Havemeyer will afford the requisite space, not only for instruction, but for the housing of the Museum of Chemical Technology, probably now the finest in the world.

The New York University is a sister institution that Mr. Havemeyer has not forgotten. The laboratory which bears his name is one of a group of new and imposing buildings which have recently been erected on a site remote from the historic structure in which Draper and Morse made themselves famous by their experiments in science.

There are also several technical schools which form an adjunct to those which have been already mentioned. The Cooper Institute in New York, Stevens' Institute in Hoboken, the Polytechnic and Pratt Institutes in Brooklyn, are among the number.

By a recent enactment, Brooklyn has become a part of greater New York. We shall therefore look for a rapid growth in her institutions of learning. Brooklyn is a city of homes and factories. None appreciate this better than her men of science, and the efforts of those like Professor P. T. Anstett, the President of the New York Section of the American Chemical Society, whose personal kindness to myself I desire to acknowledge, in building up her educational institutions will surely be recognised by all classes of her citizens.

I have received reports from many institutions in the United States of America. From them I note that they are modelling their curricula and equipments upon the best European plans; and it is worthy of note that private munificence is more frequent there than with us or even on the Continent. Dr. Seth Low has enthusiastic praise for our old universities, and he differentiates, I think rightly, between a college and a university. "A college is a place for liberal culture, a university one for specialisation based on liberal culture." This is true certainly of the German high schools and universities, and it should be so in Britain. Therefore the recent movement for a teaching university in London, affiliated to or replacing the London University, is a good thing. Parenthetically I desire to record my opinion that no scheme of education in Britain will be of much practical use which does not provide for the graduated affiliation of the schools, colleges, or high schools and universities. Boys and girls too—"persons"—should be able, with sufficient educational fitness, to pass with ease and economy from the elementary to the secondary, and from the secondary to the high, and from the high schools to the universities, each step being based upon the possession of a sufficiently high standard of knowledge by the student. In Dr. Low's report it was pleasant to see mention of the "John Tyndall" fellowship; and of the "Barnard" medal, in connection with our countrymen, Lord Rayleigh and Professor Ramsay. And, gentlemen, this educational enterprise is going on rapidly and everywhere in the "Britain beyond the sea." Let us beware, and be up and doing before it is too late.

Yet here at home the modern technical schools and colleges so rapidly spreading through the country owe their inception in most cases to the generous impulses of men who felt the great and imperative need of scientific training. Not the least generous donors have been the Companies and Guilds of this ancient City of London, which, besides supporting the City and Guilds of London Institute referred to above, at a cost of 25,000*l.* a year, do liberal work of their own. Primarily trade guilds, the progress of the times and commerce diverted them from their original purposes. Latterly, however, the governing bodies have been inspired with a desire to devote the funds, in some cases magnificently

increased by enhanced values, to educational and public uses. I find, then, that the Corporation of the City of London itself, the Mercers', Grocers', Fishmongers', Merchant Taylors', Salters', Ironmongers', Cloth Workers', Dyers', Armourers', Skimmers', Plasterers', Turners', Leathersellers', Pewterers', Bowyers', Brewers', Cordwainers', Cutlers', Plumbers', Coopers', Painters', Joiners', Fan-makers', Loriners', Shipwrights', Spectacle Makers', Frame Work Knitters', and the Carpenters' have each and all, in various ways and degrees, according to the means at disposal—for the funds of some are very small,—been contributors to some form of general, scientific, or technical education. For instance, the Drapers' Company has practically sustained the People's Palace as an educational institution. The Goldsmiths' Company, whose immediate Prime Warden is our Past President Sir Frederick Abel, has built and maintains that fine institution in the south-east of London—the Goldsmiths' Institute. This Company is pledged to an annual expenditure upon technical education of not less than 11,000*l.* During the past 18 years it has expended for that purpose 200,000*l.*, and all this out of its private funds. The Fishmongers' Company, besides certain sanitary functions, contributes 4,000*l.* a year to the City and Guilds Institute, supports the Plymouth Marine Laboratory and similar objects.

The Carpenters' Company, in whose hall we to-day are welcomed, has done good, practical work, as I can personally testify, in its Institute at Stratford, where, besides baths, recreation ground, and cookery, dress-making, and ambulance classes, it has established handicraft workshops in metal and wood, besides classes in art and science correlated to the handicrafts, where the underlying principles are taught. Its inclusion as an organised science school under the Science and Art Department caused the erection of a very well equipped chemical laboratory and physical lecture rooms. In Great Titchfield Street its technical and handicraft classes are a great success in classes for plumbing, smiths' work, masonry, wood and stone carving, &c., and the Company is obviously doing a great work in true technical education in which they have had the co-operation of the Masons', Joiners', and Painters' Companies. The Company is associated with University and King's Colleges in certain classes. Incidentally, I may mention that now this Company has been made "Trustee" for the administration of no less a sum than 50,000*l.* for a certain benevolent purpose—a mark of confidence worthy of note. The Company has during the last 10 years expended 26,000*l.* upon the Institute referred to, and this year it has spent 3,400*l.* on technical and 700*l.* on general education.

In the towns or cities where our Sections exist institutions of equal importance have been founded, some of them being affiliated to the Durham, Victoria, and Welsh Universities. These have benefited in some cases by the wisdom of the City Companies. When I was the guest of the Society of Dyers and Colourists at Bradford a little while ago, my neighbour was the Prime Warden of the Dyers' Company, by no means a rich company; yet the Bradford Technical College benefits from it in its dyeing department. The Yorkshire College, founded in 1874, where we received the hospitable welcome from our united Section of Leeds and Bradford which we shall long remember, has been materially assisted by the Clothworkers' Company since the commencement of that enterprise in technical education. That Company has taken the whole charge (both of capital and maintenance) for those subjects which it regarded as essential to the industry peculiar to its own origin

and traditions. These subjects are now represented by three departments, viz., textile industries, dyeing, and fine art. The capital outlay in land, buildings, and equipment has been 34,596*l.*, and an annual contribution of 2,300*l.* from the Clothworkers' Company added to the students' fees provides the total cost of maintenance. The Company has evidenced its continued approval by voting, in June of this year, a further capital sum of 10,000*l.* for extensions in the dyeing departments in the form of a research laboratory, and in the papers last Friday we find an additional 5,000*l.*—making 15,000*l.*—that has been voted. This Company has spent during the past 10 years, 1886-95, the sum of 176,791*l.*, or over 17,600*l.* annually, out of its private as distinguished from trust funds. I desire to be understood as making no comparisons between the work of one company or body and another, but merely as illustrating the revived spirit of help for the purposes for which the companies originally existed. A perusal of the published reports will show that large sums have been given; and in addition to special benefactions the City Companies have subscribed through the City and Guilds of London Institute in the past 18 years a sum of 480,000*l.*, of which 150,000*l.* has been expended on buildings and equipment, and the remainder on maintenance, scholarships, prizes, and grants-in-aid. In Nottingham there exist very complete and suitable buildings and equipments, and in chemistry possesses in Dr. Clowes one of our ablest teachers. In Manchester, the Municipal Technical College, now being enlarged, has done splendid work; and in Birmingham, technology takes no second place in Mason's College, the Midland Institute, and the recently opened Municipal Technical Schools.

Now, with the resources of this wealthy country, the practical spirit of its people, the freedom from State interference in any needless degree, and the public spirit of its citizens, we ought to remain very little longer in such a state of backwardness. We should not, if half the exertion and zeal manifested in sport and expended thereon, to the estimated sum of 38,000,000*l.* annually, were devoted wisely to education. With high schools and technical colleges providing instruction in the application of science and art to industrial processes, we are following slowly and tentatively after those in America, as instanced before; the *École Centrale des Arts et Métiers* of Paris, founded in 1829; that of Berlin, founded in 1879; those of Munich, Hanover, Karlsruhe, Stuttgart, and other towns in Germany; of Vienna; and of the *École Polytechnique Fédérale* of Zürich, founded in 1855.

A despatch has just now been received from H. M. Chargé d'Affaires at Berlin, stating that a Government chemical dyeing school has recently been opened at Crefeld, which has cost about 20,000*l.*, exclusive of the machinery and fabrics, which have for the most part been presented by private manufacturers. The school contains laboratories for research and educational purposes, as well as a complete collection of dyeing machinery, and an exhibition showing the result of different processes.

The establishment has been lately visited by the manager of one of the greatest dyeing works in Lyons, who is stated to have expressed the highest opinion of the institution.

It is but necessary that the State shall admit the need for action, define the steps by which that need shall be met, and then resolutely carry them out. It discovers sources of revenue for armaments to protect our trade and manufactures, without which our Empire is a "vain show," but it practically "shuffles the cards" when its citizens are to be

trained for the maintenance and development of that Empire. Mr. Stanford, at Edinburgh, said what my predecessor endorsed and predicted would become "classic," namely, "that we ought to thrust our national head into our national pocket, for it was big enough, if we were not prepared to put our hands there." A member of this Society, a valued friend of mine, says "he regards the payment of 53,000,000/ for our 'defence,' equalling 30s. per head for every person in the kingdom, as an 'insurance fund'; and in like manner money spent on good education is a true 'insurance fund.'" I agree with him; for about 7s. 6/ per head of the population is spent on the "insurance" of education (pp. 517-521). Centralisation may have its defects, but I confess to feeling strongly that the recent Governmental scheme has met a deserved fate. Its policy was allied to a matter—that of aid to denominational schools—which is good and right enough in its way, but which has only a remote relation to the great educational needs of this hour, namely, the preparation of the citizen for earnest and effective competition with our great Continental and even American rivals. I think the power of unlimited and unchecked expenditure by those directing our system of elementary education is most mischievous, and almost the only instance of unchecked expenditure by local bodies. I have given some statistics in tabular form, abstracted by Mr. G. T. Holloway. (See Appendix, p. 520.) The results are disappointing, if not fallacious. I venture the opinion that every child should be taught the elements of knowledge, and taught free of expense; but, because free, therefore economically and effectively. I think that the essentials are reading, writing, arithmetic, elementary geography, first of one's own country, the history of our own land, freehand drawing, drill, one foreign language, and perhaps vocal music. I doubt the wisdom or expediency of going beyond this for 50 per cent. of the children now attending elementary schools, except perhaps one foreign language. Where fitness or desire comes in, secondary education may begin, and State aid and endowment may, and should, largely predominate; but no harm can be done, on the contrary, if at this stage self-help and parental responsibility should be obligatory. Our continuation schools are excellent means of improvement to many otherwise engaged in the day, provided, of course, that they personally desire to improve or learn. Our Polytechnics should be subsidised in all cases by the State, even if a primary condition of such support were the erection of suitable buildings and partial equipment by the locality or by private munificence, and their maintenance placed upon a reliable and practical basis. To my mind one defect of schemes existing and proposed is that their government is handed over to unfit or irresponsible bodies—unfit because either narrow in view or "faddists" in purpose; irresponsible because subject to the caprices of the local taxpayer, and because the "boards" are composed of far too many members. I am aware that to carry out consistently and effectively any connected and systematic scheme of education, primary and secondary, would require a reconstruction of our whole system of local taxation, and a good thing too. But, in my reading of the literature of education and of the report of the Royal Commission on Secondary Education of 1895, I fail to see that the root of the matter is got at, or that any serious attempt is made to devise, much less to carry out, any effective system. What is really recommended therein is a utilisation of existing bodies. The report referred to, p. 326, says: "The 'system' which we desire to see introduced may rather be described as coherence—an

organic relation between different authorities and different kinds of schools which will enable each to work with due regard to the work done by others, and will therewith avoid waste, both of effort and money. Of the loss now incurred through want of such coherence it is impossible to speak too strongly." We may sincerely hope a Bill to meet this will not again be wrecked on a sectarian issue, in my opinion, irrelevant to the need of the hour. As is well known, education in Scotland, and even Ireland, is better than in England. In Scottish high schools the high pass certificate is an entrance to the university. The fees are low and the bursaries or scholarships numerous. Similarly in Belfast and Dublin. Our great rival, Germany, has, we all know, effectively tackled this matter, as she does most things. I must not forget that we are members of the Society of Chemical Industry. Applied or industrial chemistry requires a wide range of knowledge for its successful prosecution, and the classification of subjects in our Journal indicates very fully how wide that is. The engineer and artist, the physicist and mathematician have places; but we naturally and rightly think most of the chemist, and that, too, in the broadest sense. I am not going to discuss who best can manage a factory or most successfully conduct chemical operations, but personally I would entrust the general management to the commercially-minded engineer with a sound knowledge of chemistry than to the profound chemist alone. We have been reminded in every preceding Presidential address of the superiority of German methods. The employment of 40 or 80 chemists here or there has been held up to us as the necessary element of success; so much so has this been the case that there is scarcely a reference to qualifications for management or conduct of business. I strongly commend to your perusal a paper in the June number of our Journal entitled "The Education of Chemists," read by Dr. Duisberg, the technical manager of the great firm of Bayer and Co., of Elberfeld, and discussed in the New York Section. One hundred chemists, all carefully selected from the universities and technical high schools, and 25 engineers similarly selected, are employed.

Dr. Duisberg says "that they give the preference to those who, after passing their examination, have worked one or two years with one of the professors with whom we are associated. When such a chemist joins our service we do not expect—if, for instance, he should enter the department of colours—that he should even know what a colour is. We have found it most satisfactory if we ourselves introduce the young chemist to our special field. For that purpose every chemist must first pass through our experimental dye and print laboratory, so that he learns dyeing and printing and becomes aware of the requirements of the dyers' industry as regards dyeing properties and the fastness of colours. When the chemist has finished in this laboratory he is introduced to the scientific laboratory, the function of which is to keep us and our chemists informed of everything new that appears in the field of our manufactures in literature, patents, &c., and it is at the same time principally the laboratory of inventions. In this our scientific laboratory alone at the present time more than 20 chemists are occupied. Here the young technical chemist must produce a few of the well-known dyestuffs of the greatest variety of groups. He must experiment with those colours of our competitors that we find in the market, and only then he will slowly work and prepare for the field of inorganic chemistry. Inorganic chemistry is, scientifically and technically, the foundation of the whole

structure of applied chemistry, and if the foundation is weak the whole edifice will surely suffer."

I quote a paragraph referring to a statistical enquiry of the author's.

"Of 633 chemists, who find occupation in these 83 works (amongst which are 13 inorganic industries, 11 which manufacture organic intermediate products, 10 wood- and coal-tar distilleries, and nine tar-colour works, as also 10 works for the manufacture of pharmaceutical products and perfumeries), there were 70 per cent. that had passed their examination at a higher German school—the gymnasium or other preparatory school, 45 per cent. that had received their education exclusively at the university, 17 per cent. exclusively at a technical high school, 35 per cent. both at the university and at the technical high school; so that when we divide the two last into equal parts, 65 per cent. had studied at universities and 35 per cent. at technical high schools. Of all these chemists, 68 per cent. had passed the doctor's examination, and only 15 per cent. the diploma examination of the technical high schools, whilst 15 per cent. had passed no examination whatever."

I think our estimate should be affected by the consideration that there are comparatively few industries, possibly none besides the "colour" industry, which demand a "big" scientific staff; most require but two or three, and many only one chemist (I do not mean a "tester"); but there are none which can afford to dispense with "science." Here, on one hand, our critics err, on the other our manufacturers. Nevertheless, I take this opportunity of saying that British "colour" industries have revived considerably, largely owing to a practical recognition of this fact. I would further remind you that the statements as to large profits in German industries are by no means as "rosy" as they are painted.

I am quite sure we shall all agree that accurate knowledge is requisite, based upon accuracy of observation, and, personally, I know no better training for a technical chemist than that for an all-round pharmacist. He must be cleanly in manipulation, accurate in judgment, ready in resource, observant in habit, and prompt in execution. In America, colleges of pharmacy abound, and those I saw in New York, Boston, Philadelphia, and Baltimore are fine and well-equipped institutions. Now, what is our position? First, I believe our elementary training is defective; we "Britishers" succeed often by our instinctive common sense. When our young men go in for the pursuit of science, they generally are in a hurry. Whatever the reason, they rush through the curriculum and go to "business." They want, or their guardians want them, to earn something. Sad economy; when the drudgery is just over, when knowledge and insight have arrived and the learner begins to know the value of his tools; that is the time selected for "nipping the bud." I venture to think that it is then that sacrifice on all sides should be made. The student should restrain his impatience; the guardian, when possible, practice the principle of faith, which is the "substance of things hoped for," and supply the "needful" a little longer. If this were done, and chemists took *five* years in the making instead of *two* (the average) or *three*, the market would be less crowded and the price obtainable for the "better article" much higher. I know a gentleman of considerable ability who asks "what future is there for a chemist?" I fancy none!—for him. He lacks faith in himself.

Depend upon it, in the process of "further study," none but enthusiasts would abide. I honestly believe, gentlemen, that the fault is not in the ability of our professors and teachers—think of

their names!—nor in the equipment of our institutions, although much improvement is possible and desirable; nor even in the natural ability of the students (an eminent professor tells me he has ready 18 or 19 good men, 12 of whom certainly are equal to any turned out of continental laboratories, yet no one wants or asks for such men); but in the inability of the capitalist, broadly speaking, to discern aright true fields for enterprise. I refer not of course to the enterprising citizens of Britain who made her early successes in every field of industrial chemistry, and who still hold high and eminent positions, and among whom some of my predecessors in this honourable office stand out boldly, second to none in their special fields of industry. How many of our young men with advantages in the way of leisure, money, and friends are there preparing to continue the good work of their fathers, and retain the prestige of the names so hardly won in the struggle for existence. Nor do I refer to the difficulties which our fiscal system, our patent laws, or railway and dock administration place in the way of British industrial enterprise. But I do think—and I take entire responsibility for the utterance—that the commercial and scientific education of our business men is such that the capitalist does not "know a bad thing when he sees it." Hence the yards of advertisement about "nothing," the flotation of equally "nebulous" ventures, and the consequent disappointment and discouragement to British industrial and especially chemical enterprises. Dr. Duisberg referred in his paper to the fact of an inquiry as to the examination of technical chemists by the State. I have quoted his figures; but Mr. Robert L. Mond reminded me a little while ago of the results of inquiries as to the kind of men who were technical chemists in Germany which had appeared in the "Chemische Industrie" under the title of the "Education of Industrial Chemists." In Vol. 19, No. 1, 1896, pages 1 to 4, appears an article by Drs. Hempel and Otto N. Witt, to which I refer you for details. Replying to a series of questions put to 187 employers, 123 of them referred to 932 chemists. It appeared that 390, or one-third, were purely university men, 532 being wholly or in part trained at technical high schools, 338 among them having been educated solely at these schools. The estimate of the students themselves as to the respective value of a high school diploma and a university degree is shown by the fact that only 125 of the 338 high school students (or 37 per cent.) went in for a diploma examination, whereas 307 (or 80 per cent.) of the university students went in for the "degree" examination. This evidence of the value set upon a degree is further strengthened by the circumstance that 314 of the high school students afterwards proceeded to take up the university degree, that is, 60 per cent. of the total. It would appear that this State examination of chemists had special reference to a State decision to submit to examination chemists taking up foodstuffs for their speciality. Hempel and Witt pertinently ask "whether it would not be advisable to press for a similar examination in order to stamp the acquirements of a chemist with the authority of State recognition." Let the Institute of Chemistry mark, learn, and inwardly digest this matter. Evidence of training is what it demands of its latest Fellows, and it is evidence of scientific training that we "industrials" want, not only for ourselves, but for those who must in any progressive relation be our allies, counsellors, and assistants. In a word, we may afford to rely largely upon our instincts as "Britishers" for public safety and polity, and the management of our

own affairs. But we cannot fail to note that the legal obligation (so intensely specialised in Germany) to avoid offence to neighbours has been productive of enormous direct financial and economic good, and the scientific aid we need here can be had if we only demand the right article and give the right price. I cannot conclude this reference to training without intimating that the conditions of scientific employment in Germany differ from our own. Here usually a man comes and goes. There, he stays—he must; and whatever his industrial success, the improvements belong to his employers, and rightly he, by deliberate agreement, shares in the profits thereof so long as employed. The need exists for sound men and surely can be satisfied. Let citizens, institutions, professors, and students rouse themselves to supply this great demand, and speedily the State and public bodies must listen to the "call," and here, as in Germany, protect our industries, not by tariffs possibly (undoubtedly the glass, sugar, and other industries owe their present position to the protective system prevailing on the Continent), but by a sound system of education—education even in economies for the leaders of our workmen. The two great obstacles to the development of British industries are, the demands for prohibitive scales of wages, especially in "constructional" fuel supply, and the examinational part of our educational system, which is bad, but there is considerable difficulty in eliminating it altogether. There is an art in "examining"; indeed, as Professor P. T. Austen, of Brooklyn, U.S.A., puts it, "it is part of the science of pedagogy, which so few understand." Few really can "examine," as we know, and the often repeated strictures of Professor H. E. Armstrong are deserved. He says, in a recent address:—

"The students who follow such courses become mere prigs—some few, it is found, can retail more or less of the information imparted to them to an examiner—provided always that he lose no time in interrogating them—but they cannot make any effective use of it. Many, doubtless, are entertained, if not interested, at the time; a few, perhaps, are attracted, but if so, they start with entirely false conceptions of the aims and methods of science, and rarely recover their proper mental balance. The injury that is done when those who have been instructed in such a manner themselves seek to teach is incalculable.

"As have many others, I have long protested against the system, and it is fairly generally admitted to be a wrong one. But yet we do little to get 'forrarder,' the fact being that the deadening effect of our methods of training is such that we teachers too often go forth to our work mere machines, with the spirit of inquiry and adventure crushed out of us—slavish imitators of a long series of misguided predecessors, ever taught to follow with unquestioning obedience. And yet we English pride ourselves on our individuality, forsooth!

"What is the result? Our nation is gradually being beaten in every quarter, in every field. When this occurs in athletics, 'Punch' and the public not only note the fact, but the former advises as to the one and only remedy against future failure—for this week, speaking as Brother Jonathan, he remarks, 'Say, John, you'd better go into training again'; and the lesson will be taken to heart. But in the case of the matters which I have been discussing, there is no question of going into training again; we have not yet even begun to train properly. The nation does not know enough to understand how faulty is our system, and how absolutely we court failure by adhering to the old 'classical' methods,

which experience shows to be unfit methods of teaching classics even. And when, half perceiving this, we seek to change, we jump straight from the frying-pan of blank ignorance into the fire of technical education, where, as a rule, we find but our old foe—the dogmatic teacher—in thin disguise, and consequently are no better off."

The two professors are at one in their belief in the value of what they call manual and sense training; the cultivation of the power of correct observation and proper inference therefrom being the great problem of education. An excellent illustration of this is furnished in the paper read by our Honorary Foreign Secretary in New York, in November last, on "The History of an Invention," where is described how a striking discovery was made, merely as a consequence of systematic observation and consequent research (see *Journal*, 1895, 945–946). I commend to you a perusal of Dr. Armstrong's letters in "Nature" and elsewhere; his address at Toynbee Hall, in October 1895, on "The Useful Study of Science," wherein he regards America as a serious rival; and, still more, his contribution to the memorial lectures on Hofmann in the June number of the *Journal of the Chemical Society*. Everyone should read in the same number the contributions of your Past Presidents Abel and Perkin, the latter of whom to-day maintains his active and keen interest in scientific research, and quotes the following from the "North American Review":—

"It is fair to hold that the country that has the best chemists will, in the long run, be the most prosperous and the most powerful. It will have at the lowest cost the best food, the best manufactured materials, the fewest wastes and unutilised forms of matters, the best guns, the strongest explosives, the most resistant armour. Its inhabitants will make the best use of their country's resources; they will be the most healthy, the most free from disease; they will oppose the least resistance to favourable evolution; they will be the most thrifty and the least dependent on other nations. The education of its people in chemistry and the physical sciences is the most paying investment that a country can make. Competition to-day between nations is essentially a competition in the science and applications of chemistry."

Armstrong says: "Hofmann consistently taught this doctrine when he came among us—but to no purpose; his countrymen were wiser and have proved its truth to demonstration, and the victories won in the fields of pure and applied chemistry are rapidly leading them to introduce scientific method into the conduct of their affairs generally. Shall we ever decline to pay heed to one whom we always admired and whom we venerate?"

I suppose it is "rank heresy" to say so, but the Exhibitions of 1851 and 1892 are largely responsible for subsequent competition. We stood admiring ourselves, while our competitors imitated and improved.

Gentlemen, I must conclude some time, and I may as well do so now. An apology for an address so meagre in technical value and on so sorry a subject as our national deficiencies, is perhaps due to you; but as regards any remarks on the newest developments of technical chemistry, is there not some branch or detail that each knows best? I may be excused from telling the alkali maker what he knows already, and better than I can, although I think the figures given in the tabular Appendix to this paper may be of use. You all have access to the 33rd and latest report referred to above, of the Chief Inspector, Mr. R. Forbes Carpenter, late Chairman of the Manchester Section, and nominated again to

your Council, and there can see that in quantity of salt decomposed in Britain in the alkali processes we have not decreased. In superphosphate we are not behind Germany. The increase in national wealth from sulphate of ammonia he estimates at 1½ millions yearly, and mainly from sources hitherto neglected, and all through there is evidence of increased business as a result of increased scientific economy, and this will continue. (See this Journal, p. 541.)

Reference is made in the above report to electrical processes, and our Journal reports sectional papers of great interest and abstracts in the Journal and Patent literature. One paper may be mentioned—that on the Hargreaves-Bird process, the efficiency of which is given from actual observations as greatly increased since the paper was read. An interesting comparison of this, the Richardson-Holland, and Castner-Kellner processes is given in the "Revue Industrielle," 1197, XXVII. year, No. 1, 7th April, 25—96, and references thereto in "L'Electricien," XI., Nos. 276—282, 1896. Great interest attaches to the production of cyanides, electrically and otherwise. Also to the production of metallic carbides. The energy of M. Henri Moissan in this direction is extraordinary. The contributions of Professor Clowes, in the Nottingham Section, on the explosibility of gaseous mixtures, demand more than a passing notice. The Yorkshire and Liverpool Sections have contributed, as heretofore, exceedingly useful and practical papers. I think Mr. Douglas Herman's suggestion to have ready at hand a bottle of compressed oxygen, for use when "gassing," or even presumptive death, in works has occurred, is most important.

Of the developments of electrolytic processes much can be said and doubtless will be said in the near future, and our Sections should not, so far as I can see, be unable to render an excellent account of their proceedings in the session 1896-97. But one ought not to forget that "natural" sources of water power are denied us. We have no Niagara, nor are we in Sweden or Schaffhausen. We therefore can only hope to compete by a careful study of all the conditions—scientific, topographical, mechanical, and commercial.

I may further be excused from referring to current technology, since Dr. Mond, as President of the Chemical Section of the British Association's meeting at Liverpool in September, will doubtless cover the field in his usual able and exhaustive manner.

I might refer to the inquiry into the flash-point of petroleum which has been discussed again in the Scottish Section, and which a Committee of the House of Commons is now examining most exhaustively. I should like to observe that the thoroughness with which the Petroleum Committee is doing its work, makes one regret that the labours of the Education Committee were not equally thorough.

I cannot conclude without a reference to the work of the Council and its Committees. My predecessor, Mr. Stanford, referred gracefully to their labours in his address in Edinburgh. But I, who have been co-worker with the same men for 14 years, regard with surprise and pride the fact that the regular attendance, or postal criticism in lieu thereof by those who cannot attend, and painstaking enthusiasm, characterise their work now as at first. Surely a journal and a society which prompt such service from men whose "time is money" is worthy of support, and I sincerely hope the annual leakage of members will decrease and that the zenith of our attractiveness has not arrived, as postulated by my immediate predecessor. In the condition of our industries there is to-day greater need than ever for such a journal as ours, and the number of our members should rise rapidly to at least 5,000.

Here are some of the proof-sheets of the Collective Index promised for to-day by the indefatigable indexer, Mr. F. W. Renaut. In my opinion he has done his work nobly and well. The annual indexes were wanting in symmetrical arrangement and uniformity of classification, especially the first five years, with which another indexer had to do, so that practically a re-indexing of the whole was necessary. There are 80,000 references, and these require revision three times before the process of "alphabetisation" is completed. The Collective Index will, as soon as possible, be in the hands of those who have paid for it, and I trust very many more will require it; for no chemist, technologist, patent agent, or professor will be able to afford its absence from his reference shelf. I venture to anticipate your opinion, and to express the Society's thanks to Mr. Renaut for the way in which the work has been done. During my Presidency my efforts to justify your election of me a year ago in succession to the great men preceding me have been seconded most heartily and warmly by your Editor, Mr. Watson Smith, and the General Secretary and Sub-Editor, Mr. Cresswell. More loyal servants no society ever had. To my colleagues on the Council and Committees I say, with gratitude for their constant and courteous support, "Thank you."

I have an honour placed upon me as your President to-day, namely, to hand to Mr. John Glover, of Newcastle-on-Tyne, the medal which your Council has awarded to him for conspicuous service to applied chemistry. Being the first medal so awarded, I am in a unique position, and I appreciate the distinguished honour. John Glover's "Tower" is, or should be, known to everyone. Every text-book describes it. Nearly every sulphuric acid works has it and the Gay-Lussac tower as part of the instalment. A historical account of the tower itself, its utility and functions, is given in Lunge's classical work on "Sulphuric Acid and Alkali," Vol. I., page 421 *et seq.*, and is instructive reading to-day. Our illustrious member, Dr. Ferdinand Hurter, kindly writes the following interesting note and apologises for his absence on this occasion:—

"*Concentration.*—Mr. Glover built his first tower in 1859. At that time most of the English alkali works concentrated such of the sulphuric acid as needed concentration in badly built lead pans, the fumes from which added greatly to the discomfort of their neighbours.

"*Denitration.*—Very few works possessed any apparatus for the recovery of the nitrogen compounds. When I came to Lancashire (1867) there were no works in Widnes which recovered any of the nitrogen compounds.

"In 1863, Mr. Gossage stated that for 1½ tons of Irish pyrites, containing about 30 per cent. of sulphur, 1 cwt. of nitrate of soda was required. He estimated the output of soda as about 200,000 tons per year, and these would require 10,000 tons of nitrate of soda, then valued at 12*l.* per ton = 120,000*l.* For the same production we should require to-day only 2,000 tons of nitrate, so that the improvement in the manufacture of sulphuric acid represents, as compared with those days, and on the production of those days, a saving of nearly 90,000*l.* per annum. When we remember that a very large amount of sulphuric acid is consumed in the manufacture of artificial manures, we might almost double the sum of money which might have been saved annually in those days by a rapid introduction of the Glover tower. It is true that not the whole of this saving is directly due to the work of the Glover tower, but indirectly the Glover tower has been the means of that saving, and

JOHN GLOVER,

BORN 1817.

without it the saving would not have been accomplished. In 1867 there existed no Glover towers in Widnes, and the consumption of nitrate of soda per 100 of sulphur burnt was about 14 to 15. I am proud to say that the first Glover tower introduced in Lancashire started work on the 29th December 1863 under my superintendence, the second on the 21st May 1869, and the third in July 1870, in the works of Gaskell, Deacon, and Co., where I was then chemist. The introduction of the Glover tower alone diminished the nitre consumption from 14 per cent. to 10 per cent. on the sulphur burnt. This is about one-third of the total saving finally accomplished. But the one immediate and great advantage was the possibility of concentrating the chamber acid in this tower, so that the costly lead pans could be dispensed with. The last of these pans vanished at Gaskell, Deacon, and Co.'s works in 1871. The power of concentrating sulphuric acid to 140 and 150° Tw. with ease, is in my opinion the great progress which the Glover tower introduced into the alkali trade. Up to that time (1869) there were not only no Glover towers, but there were no Gay-Lussac towers in the Lancashire works. While it was well known that this apparatus could recover nearly the whole of the nitre otherwise lost with the exit gases of the chambers, it was also known that this saving could only be accomplished by means of large quantities of concentrated sulphuric acid, corresponding in amount nearly to the daily production of the works, and that consequently the employment of the Gay-Lussac tower necessitated fully double the concentrating plant, which was very costly for repairs and fuel. The facility with which the Glover tower permitted the concentration of the sulphuric acid for use in the Gay-Lussac, and at the same time the denitration of the Gay-Lussac acid, soon led to the rapid adoption of the Gay-Lussac tower in every works. Thus the Glover tower, being the concentrator and denitrator, enabled manufacturers to avail themselves of the Gay-Lussac tower, and in this sense we may ascribe the whole of the saving of nitrate of soda to the invention of Mr. Glover. In recent years many observations have confirmed the fact that the concentration of the vitriol in the Glover tower is not so much due to evaporation as to actual formation of a large quantity of sulphuric acid within the tower. Isolated instances have come to my notice where nearly 50 per cent. of the sulphurous acid passing into the Glover tower have been converted into sulphuric acid within the tower, and in most towers which I have examined at least 16 per cent. of the sulphurous acid is arrested as sulphuric acid. Thus the Glover tower has given hints as to further improvements in the manufacture of sulphuric acid, the development of which is rapidly pushed forward. Thus the invention of Mr. Glover has marked an epoch in the development of the manufacture of sulphuric acid; and when we remember that the pyrites consumed in this country for the production of sulphuric acid, for alkali, manure, and sulphate of ammonia, may be roughly taken as approaching a million tons per year, and that to-day no sulphuric acid works is without a Glover and Gay-Lussac tower, the national importance of Mr. Glover's invention will be apparent to all, even to those who are accustomed to no other measure of value than £ s. d. The saving that tower has accomplished, if we compared present-day consumption of nitre with the former practice, must be valued to this country alone as at least 300,000*l.* per year. The

nitrate of soda thus saved has benefited our farmers, and, considering not only Great Britain but the world, the Glover tower must, by diminishing the nitre consumption for sulphuric acid by an enormous quantity per year, have contributed towards the reduction of the price of nitre, which has fallen from 12*l.* in 1863 to 8*l.* in 1895. But beside these very palpable and highly important results which have been accomplished by Mr. Glover's invention, there is a smaller but equally lasting result achieved. The noteworthy discussions by our eminent men of the working of that tower have been the means of greatly improving the analytical methods employed in investigations connected with the manufacture of sulphuric acid, and our knowledge of the working of the process has been greatly advanced by these discussions and the investigations to which they led."

In presenting the medal to Mr. Glover, the President said: Honour to whom honour is due; and if it be any satisfaction to Mr. Glover—who took no patent and had no great reward—to receive this medal in recognition by the Society of Chemical Industry of his great and valuable services to a Fundamental Chemical Industry—it is no less a satisfaction to the members of the Society, whose mouthpiece I am to-day, to hand it to him. We wish Mr. Glover continued length of days in happy retirement, with the satisfaction that he has contributed beyond the ordinary to the well-being and prosperity of his fellows.

Mr. JOHN GLOVER, in reply, said it was difficult for him to express his feelings on receiving this tangible proof of the estimation in which the Society held his work. It was, indeed, a red-letter day in his life. He would not describe the principles embodied in his apparatus, for they were well known to the members, and had been amply described in the writings of Lange and Hurter. He would merely say that the discovery or invention of his tower was by no means accidental. In 1847 or 1848, the idea occurred to him that there would be a great saving of expense and material if he could succeed in breaking up the affinity between the sulphurous and nitrous compounds in Gay-Lussac acid without going through the operations of cooling and re-heating which were then performed. His first experiment was simply to heat the compound, and the result was to confer on the sulphuric acid a greater power of holding the nitre, not a particle of which was evolved. Then the idea of a deoxidising atmosphere occurred to him, and that idea was growing in his mind for fully ten years, during which time he was devoting his whole attention to the erection of a vitriol work for the late Mr. Hugh Lee Pattinson and the working out of that gentleman's patented process. Then he returned to his own experiments, and by using a deoxidising atmosphere succeeded in dissociating the sulphurous and nitrous compounds of the Gay-Lussac acid. The experiments were on little more than a laboratory scale, but they proved the practicability of his idea, and the Glover tower was the result. When it came to be worked on a manufacturing scale, his apparatus proved to have the additional power referred to by Dr. Hurter of condensing, not only the Gay-Lussac acid, but the whole of the acid made in the process. That fact greatly enhanced the value of the invention, which was rapidly taken into use by the trade, not only in England, but on the Continent, wherever sulphuric acid was made. He would not detain them by any further references to his work, but would simply say to the Council and to every member of the Society that he thanked them sincerely for their recognition of any services he had rendered to the science of chemistry and to the technical application of that science to the common purposes of life. He derived great pleasure also from the thought that his name should be coupled with that of one so eminent in the science of chemistry as Gay-Lussac.

APPENDICES TO

TABLE I.—UNITED KINGDOM.

	{ Value ... £ 127,186	180,749	196,845	147,042	173,079	
Cochineal, granilla, and dust.....	{ Quantity Cwt. 26,330	21,440	14,766	14,228	11,941	
	{ Value ... £ 255,568	133,254	81,081	85,380	95,688	
Cutch and gambier.....	{ Quantity Tons 30,048	26,827	32,219	26,312	28,352	
	{ Value ... £ 605,003	710,721	821,918	565,565	654,116	
Dyes obtained from coal-tar.....	{ Value ... £ 415,706	386,623	551,880	497,539	509,750	
Indigo.....	{ Quantity Cwt. 95,272	100,243	104,423	94,314	85,308	
	{ Value ... £ 2,605,841	2,455,968	2,483,031	2,119,849	1,907,555	
Madder, madder root, garancine, and murex.....	{ Quantity Cwt. 23,337	21,769	23,208	24,721	21,395	
	{ Value ... £ 33,207	28,420	31,670	36,858	26,812	
Myrobolans.....	{ Quantity Cwt.	
	{ Value ... £	
Safflower.....	{ Quantity Cwt. 1,298	980	1,794	715	1,394	
	{ Value ... £ 4,848	3,511	7,109	2,967	5,334	
Sumach.....	{ Quantity Tons 13,365	14,876	11,704	11,157	13,083	
	{ Value ... £ 195,945	215,268	165,651	162,051	178,464	
Valonia.....	{ Quantity Tons 35,604	30,468	34,447	29,487	34,227	
	{ Value ... £ 525,361	484,228	521,621	465,112	483,941	
Substances and extracts, unenumerated.....	{ Value ... £ 749,027	892,797	791,864	752,259	698,705	
Dye-woods:—						
Logwood.....	{ Quantity Tons 41,262	54,842	68,626	68,549	55,598	
	{ Value ... £ 210,005	292,540	384,950	374,373	290,714	
Unenumerated.....	{ Quantity Tons 26,252	36,630	22,929	26,991	22,446	
	{ Value ... £ 192,213	230,499	147,203	157,153	125,177	
Galls.....	{ Quantity Cwt. 30,066	39,552	37,397	83,268	56,222	
	{ Value ... £ 89,712	108,945	87,413	118,908	98,036	
Gum:—						
Gum, kowrie.....	{ Quantity Cwt. 39,621	70,289	62,378	82,266	44,724	
	{ Value ... £ 116,467	217,521	182,633	258,244	133,056	
„ lac, seed, shell, stick, and dye.....	{ Quantity Cwt. 112,025	115,427	112,479	119,511	107,241	
	{ Value ... £ 598,357	490,428	462,372	383,102	305,856	
„ of other sorts.....	{ Quantity Cwt. 108,289	117,945	108,252	104,880	88,317	
	{ Value ... £ 346,420	346,251	321,508	300,969	311,969	
Gutta-percha.....	{ Quantity Cwt. 72,636	63,809	62,713	53,839	40,697	
	{ Value ... £ 539,814	476,884	462,746	347,133	269,808	
Metals:—						
Copper, ore and regulus.....	{ Quantity Tons 152,068	163,781	186,679	189,373	152,415	
	{ Value ... £ 2,660,836	2,936,208	3,175,066	2,883,368	2,116,615	
„ unwrought, part wrought, and old.....	{ Quantity Tons 37,785	38,097	42,235	43,997	45,185	
	{ Value ... £ 2,522,393	2,413,795	2,329,175	2,093,158	1,884,801	
„ wrought, unenumerated.....	{ Value ... £ 80,138	74,546	39,252	43,224	37,462	
Iron, &c.:—						
Iron, ore.....	{ Quantity Tons 3,284,946	3,491,673	2,730,829	2,822,308	2,878,499	
	{ Value ... £ 3,663,091	2,750,870	2,114,600	1,957,199	1,894,626	
„ bars.....	{ Quantity Tons 139,229	122,895	115,486	122,597	105,466	
	{ Value ... £ 1,306,457	1,236,735	1,166,948	1,220,491	957,057	
„ steel, unwrought.....	{ Quantity Tons 5,935	4,517	6,723	11,208	12,682	
	{ Value ... £ 67,172	60,407	88,052	113,057	112,342	
„ and steel, wrought, unenumerated.....	{ Quantity Cwt. 3,444,316	3,880,676	3,792,440	3,474,395	3,537,652	
	{ Value ... £ 2,474,898	2,870,813	2,693,422	2,361,384	2,200,265	
Silver ore.....	{ Quantity Tons 750,079	1,090,542	1,089,768	1,085,227	1,030,488	
	{ Value ... £ 41,876	60,702	67,658	60,129	54,121	
Zinc, crude, in cakes.....	{ Quantity Tons 708,877	640,292	700,154	848,187	774,938	
	{ Value ... £ 563,478	407,394	601,603	803,282	663,629	
„ manufactures.....	{ Quantity Cwt. 396,466	498,206	390,157	590,885	326,004	
	{ Value ... £	
Oil:—						
Train or blubber, and sperm.....	{ Quantity Tons 15,445	17,156	17,489	18,380	15,384	
	{ Value ... £ 531,663	604,746	550,805	529,412	361,417	
Animal.....	{ Quantity Cwt. 67,877	82,629	95,811	121,498	113,482	
	{ Value ... £ 157,617	193,597	194,636	229,971	188,120	
Coco-nut.....	{ Quantity Cwt. 133,782	210,874	244,399	185,496	156,775	
	{ Value ... £ 210,654	365,716	396,288	276,221	214,346	
Olive.....	{ Quantity Tons 23,450	31,953	17,243	24,227	20,664	
	{ Value ... £ 947,154	1,198,935	715,964	981,348	791,245	
Palm.....	{ Quantity Cwt. 813,870	749,422	841,012	905,139	1,004,419	
	{ Value ... £ 1,249,866	1,315,559	1,408,763	1,217,816	1,050,459	
Seed.....	{ Quantity Tons 14,507	10,524	12,528	12,910	16,315	
	{ Value ... £ 476,807	366,489	388,118	368,130	396,126	
Turpentine.....	{ Quantity Cwt. 358,994	350,138	402,639	398,323	294,451	
	{ Value ... £ 640,939	565,902	590,533	587,927	391,879	
Chemical, essential and perfumed.....	{ Quantity Lb. 695,778	779,844	795,943	805,597	813,405

TABLE III.

GERMAN TRADE. (German figures.)

German Exports (1881-1894), to all Countries, of Dyes, Aniline and Similar; and Spirits of all Kinds.

Year.	Dyes, Aniline and Similar.		Spirits of all Kinds.	
	Kilos.	Marks.	Kilos.	Marks.
1884	1,822,300	34,167,000	75,133,600	32,567,000
1885	1,646,100	31,816,000	89,727,500	28,481,000
1886	5,702,400	38,776,000	76,589,500	23,449,000
1887	6,514,400	42,553,000	58,237,500	18,975,000
1888	6,906,000	49,055,000	35,956,000	12,493,000
1889	6,974,800	38,361,000	32,459,000	13,751,000
1890	7,279,700	37,854,000	37,865,500	14,796,000
1891	8,679,900	44,267,000	21,003,900	10,470,000
1892	10,725,100	52,553,000	16,865,400	4,659,000
1893	11,559,900	53,176,000	16,057,700	4,682,000
1894	12,368,100	53,183,000	16,955,500	4,820,000

German Exports (1885 to 1894) to the United Kingdom.

	Marks.
1885	452,797,000
1886	442,741,000
1887	490,764,000
1888	479,875,000
1889	646,737,000
1890	689,526,000
1891	679,307,000
1892	628,980,000
1893	669,967,000
1894	631,812,000

Note.—Tables I., II., and III. abstracted by T. Burton, of the staff of the London Chamber of Commerce.

PRICE OF PLATE GLASS PER SQUARE FOOT.

Area of Plate in Square Feet.	1802.	1835.	1856.	1862.	1884.	1889.	1895.
10	s. d. 15 3	s. d. 9 5	s. d. 4 6	s. d. 3 7	s. d. 2 8	s. d. 2 3	s. d. 1 8
20	32 0	14 0	5 4	4 0	2 9	2 4	1 9
30	40 11	18 9	6 2	4 7	2 11	2 5	1 10
40	67 10	23 2	6 6	4 10	3 0	2 5	1 10
100	2 8	2 0

Thus, in 10 years our exports have decreased 73 per cent., whilst our imports have increased nearly 100 per cent.

* These figures include only the amounts shown in the school accounts as applied to the maintenance of the schools; not on provision of new schools, or structural alterations or extraordinary repairs.

Free Schools and Scholars.

Year.	Schools.	Scholars.	Not Free.
1893	15,914	4,236,867	889,506
1894	16,289 out of 19,709* inspected	4,377,711	821,000

* This number includes the schools to which the grant was paid without actual inspection.

Refused fee grant: 1893 = 132; 1894 = 117.

Page XII.—Evening Continuation Schools.

Year.	Departments inspected.	Scholars on Register.	No. of Teachers.	Grant.
Before new evening code.	1,977	115,582	3,037 men	£ 45,667
1894.....	3,742 (3,318 schools)	206,683	701 women	(1893) 91,540

The bulk of the students take reading, writing, and arithmetic. Next most popular are geography, needlework, and shorthand; then vocal music, life and duties of the citizen, book-keeping, mensuration, history, and domestic economy; drawing is taught in 1,213 schools, science in 803, and manual or technical instruction in 281. Of subjects for women only, cookery was taught in 468 schools (in 1893 in 243 schools), laundry work in 26, dairy work in 2, and housewifery in 23. *The opening of the classes to persons over 21 years of age has added 37,043 to the registers.* Much assistance, pecuniary and otherwise, has been obtained from county councils and co-operation of universities, &c.

Over 14 years.....	47,329	" average attendance, 125,894....	= 3.07
Present at inspection.....	1,802,269		

Page XX.—Evening Continuation Schools, 1894.

Schools.	Departments.	Principal Teachers.		Scholars.					
		Total.	Certified by Department.	Total.	Pay no Fees.	Under 14 years.	14—18.	18—21.	Over 21 years.
3,318	3,742	3,067 men 791 women	2,822 men 623 women	266,683	103,233	32,342 or 12.13%	155,459 or 58.29%	41,839 or 15.69%	37,043 or 13.89%
		3,738	3,445						

Grants are paid upon the amount of instruction given to each scholar; not, as formerly, upon the average attendance.

Page XX.—2,822 masters and 623 mistresses were certified by Department.

Page XXIV.—Elementary School Accommodation.

Year.	For Scholars.	Per Cent. of Population.	= Increase of.
1870	1,875,584	8.75	In board schools..... 2,199,111
1894	5,832,944	19.44	" voluntary 1,755,249

but, compared with 1893, the number of places in voluntary schools had diminished by 20,465, while places were increased by 90,792 in board schools.

Cost of Schools and Teachers' Residences.

(1.) 1870—1882 (Dec. 31st).—New or improved accommodation for 280,146 scholars (1,572 schools and 933 residences):—

	£
Building grants from Department.....	312,290
Local contributions (voluntary and rates), exclusive of sites given gratuitously.....	1,348,169
Total.....	1,660,369

Page XXV.—(2.) The great majority of the remaining 4,775 voluntary schools (1,475,000) which have come under inspection since 1870, have been erected, enlarged, or improved without Government aid at a cost estimated at least at 7,000,000*l.* up to 1891. Large sums have been spent since, but there are no reliable returns.

(3.) On security of rates, 2,024 school boards have provided 2,211,299 school places, the estimated cost per child being 13*l.* 6*s.* 6*d.* This includes the sites (the cost of which is often very considerable), laboratories, workshops, landdries, cooking kitchens, school board offices, &c.

The amounts of loans for building have increased rapidly:—

	£	s.	d.
1888—1889.....	779,558	13	5
1889—1890.....	818,394	15	8
1890—1891.....	1,033,395	4	8
1891—1892.....	1,343,391	13	2
1892—1893.....	1,315,265	9	1
1893—1894.....	1,939,318	19	10
1894—1895.....	2,590,797	14	8*

Page XXVI.—(Total advances of Public Works Loan Board to March 31st, 1894 = 16,522,393*l.*, of which 1,622,189*l.* have been repaid.)

(4.) 1,297 voluntary schools have transferred to school boards, and a number of schools under private management also, but on this point there is no definite information.

* Nearly double 1891—1892; thrice 1888—1889.

Children of School Age (3—13). Estimated by Registrar-General.

In 1881 = 23.9 per cent. of population. In 1891 = 23.2 per cent.

It is estimated $\frac{1}{4}$ ths might be expected to attend elementary schools.

Making due allowance for sickness, weather, &c., it is estimated that school seats should be provided for $\frac{1}{4}$ th of population = 5,010,127 places. The provision (5,832,944) is in excess, but is not evenly distributed. Generally, however, the seats are in excess of $\frac{1}{4}$ th of the present population.

Of children of class usually found in elementary schools, there were in 1894:—

Page XXVII.

Age.	Estimated Number at Middle of Year.	Number on Registers.	Percentage of Children on Registers.

RETURN made to the DEPARTMENT OF SCIENCE AND ART relating to TECHNICAL EDUCATION IN GREAT BRITAIN AND IRELAND, 1895.

THE following refers to the returns actually made by the different local authorities and only to sums expended specifically on technical education and obtained by special rates raised under the Technical Instruction Acts.

The *actual* expenditure in England, Wales, Scotland, and Ireland for the year 1893-94 was 647,631*l.* 18*s.* 7*d.*, and the estimate for the year 1894-95, 737,420*l.* 15*s.* 1*d.*

41 out of the 19 county councils in England (excepting the county of Monmouth) are applying the whole of the residue received under the Local Taxation (Customs and Excise) Act, 1890, to technical education, and the remaining 8 are devoting part to that purpose. Of the councils of the 61 county boroughs, 55 are devoting the whole of this residue and 5 a part of it to the purpose. In Wales and Monmouth practically the whole is dedicated to technical education.

In Scotland, 21 out of the 33 county councils are using all this residue and 9 part of it for technical education. Only 3 are using none of it for that purpose.

In Ireland, 9 local authorities are making grants for technical education. In the year 1893-94, 4,339*l.* 9*s.* 11*d.* was thus expended. For the year 1894-95, the estimate was 4,748*l.* 16*s.* 6*d.*

(a.) The rough notes attached, where chapter and verse are given for each statement, together with the impressions I have gained from their Reports, show that the impressions of the Royal Commissioners are that the German and other Continental teachers in technical institutions are—(1) more practical than in England; (2) travelled men; (3) linguists; (4) acquainted, by practically working in them, with procedure in foreign manufactories.

(b.) That the training in Continental technical institutions is far more practical than in England, and that the heads of manufactories as a rule insist on or encourage the working of their young workers in evening continuation classes.

(c.) That theoretical teaching, although carried on so far as necessary, is regarded as of less importance than applied science.

(d.) That languages are more largely learned by technical students than in England.

(e.) That drawing, and anything training the use together of the hand and eye, are of great importance. This (in my opinion, G. T. H.) is now pretty thoroughly done in England.

(f.) That modern technical training is not so good as apprenticeship, but as the latter is going out of fashion, the training institutions are now essential.

First Royal Commission on Technical Instruction, 1882.

This is a preliminary report on technical education in France and Italy, by Bernhard Samuelson, Henry E. Roscoe, Philip Magnus, John Slagg, Swire Smith, and William Woodall.

Page 5.—Elementary education much neglected in France until within 15 or 20 years before 1882.

Page 6.—Conscripts who could not read or write equalled 47·8 per cent. in 1833; 23 per cent. in 1866-67; 15 per cent. in 1880.

In the principal industrial centres this was not so bad—6·7 per cent. in 1866 and 5·2 per cent. in 1882.

Pages 7 and 25.—As early as June 1881 primary education was free in Paris and many large provincial towns of France, and in many of the rural communes.

They speak highly of lectures delivered on science, &c. in Paris gratuitously by men of "world-wide reputation"; such were those of the Collège de France and the Conservatoire des Arts et Métiers.

There were in 1882 over 100 art classes for adults in Paris.

There were superior elementary schools (Écoles primaires complémentaires) for literary and technical instruction, either free or very cheap. Here instruction in weaving, dyeing, &c. was given among other subjects.

Page 23.—After passing through elementary schools the children (12 years of age) are examined, and, if they fail to show sufficient knowledge, are not allowed to work full time (12 hours) in workshops and factories until they reach the age of 15.

Second Report of the Royal Commissioners on Technical Instruction, Vol. I., 1884.

Page 148.—Some idea of the thoroughness of the technical instruction on the Continent may be gained from the fact that in the classes in weaving at the weaving school in Vienna, the students, all of whom are said to be practically familiar with the loom, are given pieces of cloth sometimes composed of such mixtures as silk, mohair, wool, and cotton, and are expected to dissect them thread by thread, to determine the "counts" of warp and weft, and to count the length of each required for weaving a yard of the cloth and the cost of the individual constituents and of the finished cloth. All this work is done under the supervision of practical men acquainted with the usage in the foremost manufactories of the principal weaving districts. At this school all the students study theoretical chemistry, but only those going in for dyeing study practical chemistry, and they take a course of one or two years at it, and many students pass out into employment as "qualified dyers" without any apprenticeship.

Page 281.—The Commissioners state that the managers and foremen of Continental dyeing establishments had "high scientific knowledge combined with practical training," and that in France, Italy, Switzerland, Germany, Austria, Belgium, and Holland, "in nearly every factory or industrial establishment of importance, the directing skill was supplied by men who had supplemented a scientific education by foreign travel." They add: "In chemical knowledge, the heads of departments in colour-making and dyeing establishments are almost invariably superior to those of England, where Englishmen educated only in England are employed."

Page 297.—They add on page 297, as regards calico-printing, &c. in Alsace: "It is a noteworthy fact that in nearly every instance the employers and foremen of the establishments we visited were men of high attainments. A great proportion of them speak English, and, from frequent intercourse with English machine makers and printers, they are able to obtain accurate information on all matters relating to the development of their industry."

Page 343 to 346.—In referring to the ironworks of Westphalia, the Commissioners describe their visit to the Union Works, of Dortmund, as typical of the iron and steel industry of Westphalia.

All boys under 18 are *compelled* to attend the Fort-building schools of the town on two or three evenings weekly. An overseer at the works examines the register showing the attendances of the boys.

They state that "the managers have received the usual German technical training, are thoroughly familiar with English works and proficient in the English language."

Page 346.—*Re* the military system on the Continent, one of the managers at the Union Works at Dortmund (Westphalia) considered that it improved the men in most ways, the three years' military service making him superior in many respects. He would personally prefer a man as a workman after he had passed through his military term.

Page 383 to the end (page 540).—The Commissioners describe the various training institutions in the United Kingdom, including King's College, Royal School of Mines, and Royal College of Science, South Kensington, City Guilds Institutions, &c.

Extracts from Return made to the Department of Science and Art, showing the extent, &c. to which Funds are applied to Technical Education (including Science, Art, Technical and Manual Instruction). *Byre and Spottiswoode, 1895.*

RETURN showing the EXTENT to which, and the MANNER in which, LOCAL AUTHORITIES in ENGLAND, WALES, SCOTLAND, and IRELAND are applying Funds to the purposes of TECHNICAL EDUCATION (including SCIENCE, ART, TECHNICAL and MANUAL INSTRUCTION).

Manner in which the Funds have been expended during the Year 1895-6.

	Amount appropriated to Technical Education out of the Residue Grant in the Year 1893-4.	Amount granted to Town Councils and Urban Authorities under Section I. (3) of the Local Taxation Act.	Amount expended.										Estimated or Actual Expenditure on Technical Education for the Year 1894-5, out of (a) Residue Grant, (b) Rates raised under the Technical Instruction Acts, and (c) Rates raised under the Public Libraries Acts.		
			In aiding the Supply of Technical Education.								In Scholarships and Exhibitions.	Expenses of Administration.		Other Purposes to which Funds have been applied.	Subjects taught.
			By Grants to Grammar or other Endowed Schools (governed by Schemes established under the Endowed Schools Acts); and under special Conditions.	By Grants to Schools and Classes (other than those included in Column 6) in receipt of Aid from the Department of Science and Art.	By Grants to other Schools, Institutions, &c. They refer on page 402 to the 34 subjects in which the City Guilds Authorities examine students in technical subjects.

From page 505 to 540 they give their conclusions on their researches. They consider that we still retain the lead in most technical work, but that Continental nations are advancing more rapidly than we are.

They introduce our machinery and methods, and improve upon them in many cases.

Page 508.—The Commissioners point out that the Continental technical schools are almost entirely supported by the State. They say: "Your Commissioners cannot repeat too often that they have been impressed with the general intelligence and technical knowledge of the masters and managers of industrial establishments on the Continent. They have found that these persons as a rule possess a sound knowledge of the sciences upon which their industry depends. They are familiar with every new scientific discovery of importance, and appreciate its applicability to their special industry. They adopt not only the inventions and improvements made in their own country, but also those of the world at large, thanks to their knowledge of foreign languages and of the conditions of manufacture prevalent elsewhere."

Page 507.—The Commissioners point out that the early supremacy of the English was in part due to loss of energy and capital on the Continent during the great wars of the early part of the century, and mention that various Acts of

the last century rendered it penal to enlist English artisans for employment abroad (these Acts were repealed in 1825), and that the exportation of spinning machinery to foreign countries was prohibited until the early years of the present reign. They add that when Continental countries began to construct railways and to erect modern mills, &c., "they found themselves face to face with a full grown industrial organisation in this country, which was almost a sealed book to those who could not obtain access to our factories."

They add that the English are fully alive to the necessity of technical education, and are doing much to forward the object. Their expressions of opinion as to the future of the movement are on pages 514 *et seq.* They are not suitable for abstracting, and are not of much importance, but the conviction is stated that the "workshop is really the best technical school in the world."

Vol. III., pages 643 to 690, contain letters showing the opinions of employers of labour, officers of trade societies, &c. in the United Kingdom. Generally speaking, they refer to the great value of museums, &c., and to the teaching of drawing, but there is a good deal of divergence of opinion on other questions.

Vol. IV. contains evidence given before the Commissioners by various persons, teachers, employers of labour, &c. There is little of interest as regards science, the bulk referring to drawing and ordinary workman's employments.

Vol. V. contains accounts of various colleges, &c., with plans, &c. of their workshops, laboratories, &c.

The PRESIDENT then read the report of the scrutators, from which it appeared that all the members and officers nominated had been duly elected. That gave him the honour of announcing officially that Dr. Schunck would be his successor, and he congratulated the Society on having for its President one who had contributed more to the chemistry of natural colouring matters than perhaps any living chemist, as was shown by researches such as those to be found in the Journal of the Chemical Society (see annexed list). Dr. Schunck's scientific industry was now released from the hindrances of business, and he trusted that

health would be given to him to crown a high scientific career by some further discovery, which perchance he might divulge at our next Annual General Meeting.

A. Abstracts.

M. Memoirs.

T. Transactions.

Dr. E. SCHÜCKER proposed that a cordial vote of thanks be accorded the President for his able and thoughtful address. He did not propose to discuss that address, but he might be allowed to refer to one part of it that greatly interested him, namely, the supposed pre-eminence in technical matters of foreign nations as compared with the English. He could say of his own knowledge, however, that Englishmen had greater natural ability than perhaps any other nation, and therefore any technical shortcomings that might exist could not be attributed to that cause, but must be due to lack of scientific training. In that respect Germany was first in the race. He was not sure that in discussing this question sufficient weight had been given to one point. Much had been said about the work of the great corporations in assisting technical science. But was it not possible that there might exist a great difference of sentiment and opinion on this matter? The greatest importance attached to early education; and when they found parents quite indifferent to their boys acquiring a profound knowledge of science, languages, and everything that constituted modern culture, and attaching far more importance to cricket and other athletic sports, no amount of financial help would have any lasting effect. This could be altered only by influencing public opinion, and could best be done through the instrumentality of societies such as this.

Sir HENRY ROSCOE seconded the motion, and in doing so said he was glad to learn from the address to which he had just listened that Mr. Tyrer did not take a pessimistic view of the industry in which they were concerned. Neither did he. He believed that their Society was doing a great work in bringing scientific and practical men together. He was astonished at the progress which chemistry had made in England during the last 30 years, both scientifically and practically. They must not, however, lose sight of the important fact referred to by the President, namely, the progress of their Continental competitors. He was quite in accord with Mr. Tyrer's views as to the desirability of establishing a teaching university in London, and trusted that before many years had passed it would be an accomplished fact. That the nation was making satisfactory progress in recognising the necessity and importance of scientific research was proved by a fact to which the President had not referred. The Royal Commission for the Exhibition of 1881 was now devoting 5,000*l.* a year to the maintenance of scientific scholarships in various departments of industry. This was only one instance of the general interest now awakened in the subject of scientific education—a subject which their Society had done much and would do still more to encourage. The resolution was then put by the President-Elect, and was carried by acclamation.

The President then briefly thanked the meeting.

The Council for 1896–97 is composed as follows:—

President:

Dr. Edward Schüneck, F.R.S.

Vice-Presidents:

Chas. Dreyfus.	A. Gordon Salomon.
Dr. A. Dupre, F.R.S.	E. C. C. Stanford.
Prof. A. K. Huntington.	G. N. Stoker.
A. H. Mason.	Dr. T. E. Thorpe, F.R.S.
Bovort on Redwood.	Prof. W. A. Tilden, F.R.S.
Sir H. E. Roscoe, F.R.S.	Thomas Tyrer.

Ordinary Members of Council:

George Beilby.	C. C. Hutchinson.
R. Forbes Carpenter.	Ivan Levinstein.
R. Le Neve Foster.	J. S. McArthur.
Oscar Guttman.	B. E. R. Newlands.
Douglas Herman.	Sir Robt. Pullar.
David Howard.	Wm. Thorp, B.Sc.

With the Chairmen and Secretaries of Sections.

Honorary Treasurer:

E. Rider Cook.

Hon. Foreign Secretary:

Ludwig Mond, F.R.S.

Mr. C. C. HUTCHINSON proposed that Messrs. Miall, Wilkins, Randall, and Co., be elected auditors for the ensuing year at a remuneration of 10 guineas. This was seconded by Mr. Thos. Fairley, and carried.

Sir R. PULLAR proposed that Mr. E. Rider Cook be re-elected the representative of the Society on the Council of the Imperial Institute. The proposal was adopted.

Mr. THOS. MACFARLANE, in seconding the motion, said that as a member residing in the Dominion of Canada he would express the hope that Mr. Cook's activity in the position he was to occupy would contribute towards bringing into existence closer trade relations between Great Britain and her colonies and dependencies than existed at present. The motion was carried unanimously.

Mr. GEORGE E. DAVIS said that he was deputed by the Manchester Section to convey a most cordial invitation to the Society to hold its next Annual Meeting in Manchester. It would be, he said, 10 years since the Society visited that town, and though they could not hope to provide a programme equal to that of the present meeting, they would do their best to make the members heartily welcome.

Dr. C. DRYVER, in seconding the motion, hoped Manchester would be able to show their visitors such evidence of progress during the last 10 years as would surprise them. It was unanimously resolved that the invitation of the Manchester Section be accepted.

Mr. DAVID HOWARD moved that the best thanks of the Society be given to the Master and Wardens of the Carpenters' Company for their hospitality that day. They had heard something of what the Company had done for technical education. But their work was not to be measured merely by the amount of the cheques drawn; what was far more important was the wisdom which had guided them in applying their gifts, and the constant thought and care which they had devoted to the cause they wished to help.

Mr. E. K. MESSYATT had much pleasure in seconding the motion. The recital of the long list of City Companies that had aided technical education made him regret that there existed as yet no Worshipful Company of Industrial Chemists, in whose hall they would naturally hold their London meetings. Reference had been made to the greater encouragement given to scientific education and research by foreign Governments as compared with our own, and Dr. Schüneck had remarked on the necessity for educating public opinion. He would suggest that they should commence by educating the opinion of the Chancellor of the Exchequer, who seemed far more alive to the needs of the army and navy than to the importance of national educa-

tion. That was a wrong state of things, and he thought it should be remedied by the foundation of a much larger number of scientific scholarships throughout the country. The vote was then put by the President and carried by acclamation.

Mr. A. PRESTON acknowledged the vote on behalf of the Master and Wardens, who were unavoidably absent at that moment, and in doing so endorsed the remarks that had been made as to the importance of better technical education—which he thought applied to masters as well as to subordinates. He assured the Society that the Carpenters' Company thoroughly sympathised with their views, and were very happy in being of service to them that day.

VISITS TO WORKS AND PLACES OF LOCAL INTEREST.

After the conclusion of the morning's business, luncheon was partaken of at the Cannon Street Hotel by invitation of the London Section. The company numbered about 300. After lunch the following works were visited:—

THE WORKS OF THE COLONIAL CONSIGNMENT AND DISTRIBUTING COMPANY, LTD.

[Small installation of cold storage and refrigerating machinery under Cannon Street Station, and large installation, Nelson's Wharf, Lambeth, S.E.]

Both these installations were visited by parties of members. The following is a description of machinery and process of meat refrigeration and storage at Nelson's Wharf:—

During the year 1895 no fewer than 3,423,347 carcasses of frozen sheep and lambs, and 323,698 quarters and pieces of beef, arrived in England from New Zealand and Australia alone (without counting 1,652,625 sheep and 12,418 quarters of beef from the River Plate, and 19,432 sheep from the Falkland Islands), a total of 5,095,404 frozen sheep and lambs, and 336,116 quarters of beef in the year; and for the first six months of this year a total of 3,214,660 frozen sheep and lambs, and 155,195 quarters of beef, have been received from the same sources of supply.

The extensive buildings at Nelson's Wharf, devoted to cold storage, &c., were erected by Nelson Brothers, Ltd. Instead of entering them from the ground floor they are entered from the sixth storey, to which one is carried by a lift. Of side doors there are none, and the only entrances are just under the roof. The reason for this arrangement is that, as cold air sinks, whilst warm air rises, it is found best to have the freezing chambers as low down as possible, and to enter them from a "shaft" by means of a lift passing through the various "levels" or floors. This arrangement minimises the chance of the cold air escaping into the atmosphere outside. Arriving at the top floor, a series of rooms is found where the work of receiving, weighing, and consigning is carried on. Here there are elevators, or endless chains, with, at fixed distances, projecting irons forming "cradles" where the carcasses of sheep can be placed direct from the barges into which they have been loaded from the ocean-going steamers in the docks. Placed in one of these cradles, the sheep is carried by the elevator to the centre of the room on the sixth storey, and there it falls on to a table where men are at work sorting the carcasses according to the different brands, afterwards pushing them on trucks to the "shafts," down which they are taken to the series of freezing chambers in which they will be stored as long as may be necessary. It is possible to raise as many as 1,500 carcasses per hour in this manner from the river barges; in fact, the elevators will work much faster than the men above can dispose of the carcasses falling on the tables before them. It is no unusual thing for 12,000 sheep to be received here in the course of a day from the eight barges which are kept constantly working, though 10,000 is regarded as an average day's work.

Descending some steps into the cold storage chamber beneath, like the 'tween decks of some gigantic ship, with "bays" about 23 ft. deep on each side, most of the sheep, laid in bags, are seen piled one on top of another. The temperature is 20° F., and the elaborate series of pipes

running the whole length of the chamber and into each bay, are covered with hoar frost, which is, in places, at least an inch thick. It is necessary to have two men constantly employed in keeping the pipes clear, so that the *maximum* of cold which the pipes are capable of conveying may be secured. In the lowest of the cold chambers, however, the pipes give very little trouble, as by the time the air reaches them from the top storey it has so far lost its humidity that the deposit of rime is very slight indeed.

This floor is so extensive that it is divided into three sections, with fire-proof doors between each. There are four other floors beneath, of exactly the same size and description, and, altogether, it is possible to store no fewer than 250,000 sheep in this one building, with an absolute guarantee that they will be as fresh when they are brought out as when they were put in. The average stock in hand is about 150,000.

At the other end of the series of rooms forming the top floor one looks down upon a large covered-in yard, where, by means of lifts and elevators, a number of railway vans are being loaded with sheep, which, sent down from the sixth storey, are going to all parts of the country. This one establishment is now dealing with frozen colonial sheep and lambs at the rate of about 1,500,000 a year, to say nothing of miscellaneous thousands of single joints, and 90,000 or 100,000 quarters of beef from Queensland.

The whole place is illuminated by 1,600 electric lights, gas being only used in the offices.

The cold of the freezing chambers is produced by means of ammonia, which is first compressed, condensed, and liquefied under pressure, and then driven through the pipes until it reaches a point where, passing through an aperture about the size of the point of a needle, it suddenly expands, assumes its natural volume, and, at the same time, produces intense cold.

Defrosting Process.—The Chairman of the Company, Mr. E. Montague Nelson, has devised a process by which the frost is removed from frozen meat, the meat returning to its original state and recovering its pristine flavour and juiciness. Hurried thawing makes the meat flabby and unsightly. Mr. Nelson's system is carried out in chambers in which steam pipes are carried along an open battened floor, the warm air rising from these passes over the meat hanging in the chamber, and, by natural circulation, is attracted to a number of pipes of expanded ammonia attached to the walls, and all moisture is deposited on these pipes as snow. Four days are required to thoroughly remove the frost, which means excess of moisture, from quarters of beef and two days from carcasses of mutton; beginning at 35° F. there is a gradual rise of temperature till 55° is reached, and the meat is restored to its original state, dry and bright looking, without any of the dripping and moisture usually observed on thawed meat. Eighteen chambers are devoted to this work, capable of "defrosting" 2,000 quarters of beef and 5,000 sheep weekly.

Among the machinery, &c. at Nelson's Wharf are:—

Two De la Vergne Sterne ammonia compression machines, used alternately. Vertical compressing cylinders 12 ins. × 24 ins. Horizontal steam cylinders, compound and condensing. Capacity of each machine expressed in terms of ice manufactured per 24 hours = 10 tons.

One small machine on the above system, but with single acting compressor. Ice, tons capacity, 2. Used experimentally, but now disconnected.

One Haslam's cold air machine, compound, duplex, and condensing. Cubic feet of air, at about 80° F. below zero, delivered per hour = 170,000. Two air compressors 2½ ins. diameter, 36-in. stroke, at 80 revolutions = 350 h.p. Ice equivalent, 34 tons.

One (Smith and Vale) hydraulic pump, compound duplex condensing, and accumulator, loaded to 28 tons; pressure water = 750 lb. per square inch. Service constant. (The London Hydraulic Power Company's water is available at need.)

19 hydraulic apparatus for lifting.

One mechanical stoker engine.

Three steam boilers, two usually under steam at 140 lb. per square inch working pressure at one time. Vicar's mechanical stokers.

One general surface condenser and air pump.

THE TOWER BRIDGE.

This beautiful structure was a work undertaken by the Corporation of London for connecting the Middlesex with the Surrey side of the Thames, the original proposal for a bascule opening bridge having been made by the City architect, the late Sir Horace Jones, with whom was associated Mr. J. Wolfe Barry, engineer to the undertaking. The Bridge House Estates Committee directed the undertaking and Mr. G. E. W. Crutwell was resident engineer. The contractors for the steelwork were Messrs. Sir Wm. Arrol and Co., the contract for the work being let in July 1889, for the construction and erection of between 13,000 and 14,000 tons of iron and steel work; Mr. J. E. Tait was engineer in charge. Messrs. Perry and Co. were contractors for the masonry, and Messrs. Sir Wm. Armstrong, Mitchell, and Co. supplied the hydraulic machinery.

The bridge consists of three spans, *viz.*, two approaches on the suspension principle and a central lifting bridge. Subsidiary to the latter there are two foot-bridges at a sufficient height to allow for the masts of vessels requiring to proceed to the wharves higher up the river, to pass underneath. The middle span is 200 ft. in the clear, whilst those on either side are 270 ft. each. The opening bridge is on the bascule system, each leaf extending 100 ft. These leaves are actuated by hydraulic machinery, placed in suitable chambers in the piers. The centre of the pivot is 13 ft. 3 in. inside the face of the pier, so that the total length of each movable part from the centre of the pivot to the end is 113 ft. 3 in. The short end of the lifting part is 49 ft. 3 in. This is loaded at the end with kentledge to balance the longer arm, which projects over the waterway when the bridge is closed. Although the towers forming the principal features in the bridge appear to be of masonry, the main structure is steel; that is to say, there is a steel skeleton clothed with stonework. This method of construction adds not only to the expense, but to the weight to be borne by the foundations; it has, however, been adopted in order that the bridge may harmonise with the Tower of London.

The main piers contain hydraulic machinery for operating the bascule, and the footways above are approached by means of hydraulic lifts in the towers themselves. The length of each of the fixed spans forming the footways is 237 ft., and each consists of two cantilevers and a centre girder. The height of the columns of the towers is 119 ft. 3 in. There are three landings to each tower, the floors being of steel. The approaches to the piers are on the suspension principle, but the chains are of novel design, being formed of two segments of unequal lengths. The central bridge consists, as already stated, of two fixed and one opening span, the two fixed spans forming the high-level footway. The distance between the two piers is a little over 230 ft., and the height in the clear, above Trinity high water, is 140 ft. The waterway between the piers is 200 ft. wide.

Returning to the towers, there are four lifts to the high-level roadways, two in each tower, the cages being each 14 ft. by 6 ft. For those preferring the exercise of walking, staircases are provided.

Permission to inspect the bridge and its machinery was kindly accorded by the Corporation of the City of London (W. H. Liversidge, Esq., Chairman of the Bridge Committee), and the members, by the courtesy of the bridge-master, were conducted in parties of 25 at one time. A full and illustrated description of the Tower bridge, its history, machinery, and construction, will be found in *Engineering*, 1893, Vol. 56, Nos. 1447, 1448, 1449, 1450, and 1451; also illustrations in Vol. 57, No. 1487.

MESSRS. COMBE, DELAFIELD, AND CO.'S BREWERY.

The visitors were met at the entrance to the brewery by Mr. John Combe and Mr. Frank Wilson (President of the

Institute of Brewers), and conducted in parties of about twenty.

This brewery, situated in Castle Street, Long Acre, was started more than 100 years ago by Thomas Shackle, but the present business was virtually founded by Mr. Harvey Christian Combe at the beginning of the century, and was the scene in 1807 of the famous brew-house dinner of rump steaks and porter, given by him to the Royal Family in one of the mash tuns.

Since this time the brewery has been considerably enlarged.

The brewing plant consists of five mash tuns, of a total capacity of about 600 qrs.; from these the wort runs into the underbacks, to be pumped to the coppers, of which there are six, all boiled by Jucke's revolving furnaces; the capacity of the coppers varies from 200—500 barrels. The seven coolers are supplied with seven refrigerators for cooling the wort; from these it runs to the fermenting tuns, which vary from 100—600 barrels capacity. During the summer months the air over these is cooled by a series of brine pipes, worked by a Reece's ammonia absorption machine, capable of absorbing 600,000 thermal units per hour.

The water for refrigerating purposes is cooled by three of Hall's carbonic acid machines, each of 400,000 to 500,000 thermal units per hour capacity.

All the yeast used in this brewery since 1893 has been a single-cell yeast grown according to Prof. Hansen's system of pure yeast culture.

The pure culture is grown in Hansen's pure yeast cultivating apparatus, from which the yeast in the brewery is renewed at frequent intervals. The following is a short description of the preparation of a pure yeast culture:—

Some of the yeast, from which it is desired to prepare the pure culture, is largely diluted with water, well shaken, and a drop of it added to some liquefied wort gelatin; this is again shaken, and a drop of the mixture is withdrawn by a glass rod and spread on the under surface of a thin cover-glass which is cemented on to the ring of a Böttcher moist chamber, the other edge of the ring being made fast to a glass slide by smearing it with vaselin.

When the gelatin has solidified, the position of the cells embedded in it, is marked; it is then left for two or three days at about 50° F.; at the end of this time the specks of yeast may be taken off by a short piece of platinum wire and the wire dropped into wort contained in a Pasteur flask. From this we get a growth of yeast known to proceed from a single cell, which is used to infect other flasks, which in their turn are used to infect the Hansen apparatus. Throughout the whole process all apparatus and nutritive material must be carefully sterilised.

The pure culture once made may be preserved for years in a 10 per cent. solution of cane sugar, from which the fermentations in the Hansen apparatus may be restarted when it has been necessary, for repairs, &c., to clean out the machine.

From the large fermenting vessels, which are mostly wood—and some, wood lined with copper,—the beer is cleanned into the pontos—small wooden vessels of 5- to 10-barrel capacity; here the yeast works off, and is run into shallow iron backs cooled by water from the ice machine.

The cooperage is situated about three minutes' walk from the brewery; as the casks return from customers they are examined as to their soundness and sweetness; after having been cleaned on the rummaging machines, washed with boiling water, and steamed, they are returned clean to the brewery.

MESSRS. REID AND CO.'S BREWERY, CLERKENWELL ROAD.

About 30 members availed themselves of the invitation to visit the brewery of Messrs. Reid and Co., Clerkenwell Road, accompanied by Mr. John Heron. They were received by Mr. Tanqueray and the brewing staff, and were conducted over the brewery in parties, the machinery and various processes being fully explained. After visiting the brewing department and the ice machinery, they were conducted to the stores, where they were invited to test the merit of the "Imperial Stout" for which this brewery is noted.

RECEPTION AND CONVERSAZIONE AT THE MANSION HOUSE.

The Lord Mayor of London, Sir Walter Wilkin, and the Lady Mayoress, had on this occasion a double function to perform, two sets of invitations having been issued—one to meet the President of the Royal Society (Sir Joseph Lister) and the members of the International Conference on the Classification of Scientific Literature; the other to meet members of the Society of Chemical Industry, with their President, Mr. Thomas Tyrer, and the President-Elect, Dr. Ed. Schunck.

Over 800 guests crowded the Saloon, Egyptian Hall, and the adjacent apartments, conversing, admiring the display of civic plate, listening to the music of the band of the Royal Artillery, Woolwich, and the students of the Guildhall School of Music. The Lord Mayor and the Lady Mayoress received their guests with the state usual on such occasions.

SECOND DAY.—THURSDAY, JULY 16.

RIVER THAMES EXCURSION.—CAVERSHAM TO WINDSOR.

About 400 members and friends with their ladies started from Paddington Station for Reading at 9.10 a.m. Embarking in launches at Caversham Lock they proceeded down-stream past Shiplake, Wargrave, and Henley, to Medmenham Abbey, where luncheon was served. Unfortunately the weather was cold and damp, with a lowering sky and north-east wind. There were, however, spacious saloons in the launches, where those more thinly clad could assemble. After luncheon the launches proceeded past Great Marlow, Cliveden, Boulter's Lock, and Bray to Surley Hall, where tea was served in a large tent. After tea, the gentlemen of the Eton College Choir sang a selection of glees which were greatly appreciated. The launches then proceeded to Windsor, and the party returned by special train to Paddington at about 9.29 p.m.

THIRD DAY.—FRIDAY, JULY 17.

THE ROYAL ARSENAL, WOOLWICH, ORDNANCE FACTORIES.

On arrival at the Royal Arsenal, the party was divided into sections, each containing about 30 members. Each section was preceded by a man with a staff, bearing a number, and was accompanied by a guide in uniform to furnish explanations and to give descriptions of all that was to be seen. The whole arrangements were carried out under the supervision of the Director-General of Ordnance Factories. The following operations were seen by the members:—

1. *Royal Laboratory*.—Bullet making. Lead squirting. Manufacture of rifle bullets. Manufacture of lead cores and cupro-nickel envelopes for magazine rifle bullets; assembling and finishing the same.

2. Manufacture of solid drawn brass cartridge cases for quick-firing guns. Drawing. Indenting. Heading and finishing operations.

3. Manufacture of zinc and brass cartridge cylinders and cases.

4. Manufacture of metal time fuzes. Exhibition of specimens showing various operations.

5. Shell forging. Manufacture of quick-firing shell bodies.

6. Cast steel shell making. Sand mixing. Core making. Moulding. Casting. Annealing. Grinding, &c.

7. *Royal Carriage Department*.—Manufacture of siege, field, quick-firing, and machine gun carriages. Various operations. Exhibition and explanation of finished carriages.

8. General machine operations and work on mountings for heavy ordnance.

9. Band saw for metal work.

10. Steam saw mills.

11. Tiring gun-carriage wheels.

12. General woodwork in connection with carriages.

13. Small-arm and quick-firing ammunition box making. Machine planing, dovetailing, nailing, &c.

14. Large band saw for timber.

15. Wheel making. Turning spokes and other copying-lathe work. Making felloes. Pressing wheel together. Saddle-tree making.

16. *Royal Gun Factories*.—Oil-hardening hoop for heavy breech-loading gun.

17. General operations in connection with heavy breech-loading guns. Boring hoops and tubes, rifling, &c.

18. Breech mechanisms. Working models of breech mechanisms of heavy B.L. guns. Examination and explanation of 12-pr. field guns, and of 6-pr. and 4.7" quick-firing guns.

19. Wire winding.

20. Manufacture of field and quick-firing guns.

21. Sighting and completion of B.L. guns.

22. Shrinking hoop on to B.L. gun.

23. *Harness Stores*.—Inspection of.

LUNCHEON.

A Luncheon was provided in the Masonic Temple, Mount Pleasant, the Upper and Lower Halls of which were filled with members. The President took the chair in the Upper Hall, and Mr. B. E. R. Newlands, Chairman of the London Section, presided in the Lower one. Speeches were made by the President and Chairmen of the London and New York Sections.

Professor CHANDLER, Chairman of the New York Section, said that, with regard to the unpleasant feelings sometimes said to exist in America against Great Britain, he could assure them that if ever such feelings did exist they only lasted for a moment, and even then were entertained only by a very limited portion of the population. The majority of Americans regarded themselves almost as Britishers, and in many instances did their best to imitate the British, as was proved by the fact that in establishing the American branch of the Society of Chemical Industry they had taken the English Society as their model. Personally he could assure them that there was not a drop of blood in his veins that was not English, for his ancestors went to Boston in 1664.

After lunch, the members proceeded by tramcars from the Arsenal Gates to Charlton, near to the

WORKS OF MESSRS. SIEMENS BROS. AND CO.

Here again the members were divided into parties, each led by a guide, who described the various operations carried out in the workshops. The arrangements were under the direction of Mr. G. Palgrave Simpson. The following departments and shops were thus visited:—

Milling Shop.—Special cutters for milling small metal pieces. Capstan lathes for screws, nuts, &c. Putting together commutators for dynamos.

Winding Shop.—Winding cotton-covered copper wire on electro-magnet bobbins. Building up dynamo armatures. Winding transformers.

Dynamo Shop 1.—Lathes, drills, and boring machines. Punching machines for iron core discs, and copper end connections.

Dynamo Shop 11.—Large lathes and boring machines for heavy work, such as magnets of dynamos, bed-plates, &c. Longitudinal and circular planing machines. Electrically driven travellers.

Testing Shop for Machines.—All machines are thoroughly tested under conditions similar to those under which they will have to work. Fusing length of iron wire by passage of a powerful current of electricity.

Testing Shop for Lamps and Instruments.—Arc lamps adjusted and regulated. Ammeters and voltmeters tested and calibrated.

Electrical Fire Engine.—Can be got to work at once by attaching its electric motor driving a rotary pump to the electric distributing mains by means of a concentric cable.

Pressure Tank.—All core for deep-sea cable is submitted to hydraulic pressure, so as to search out any little defect.

India-Rubber Shops.—The raw rubber is cut up and washed under rollers, which also tear it up. It is then dried and passed through the mixing rollers, where it may have sulphur incorporated with it if it is to be vulcanised. This is done in large steam-heated vessels.

Covering Shops.—Tinned copper wires, either single or stranded together, are covered with the prepared rubber cut into strips, and with tape or braiding.

Show Room.—A museum of historical and modern apparatus and instruments.

Core Tanks.—The gutta-percha covered core for submarine cables, as well as all india-rubber core, is here tested under water at two different temperatures.

Instrument Shop and Adjusting Room.—Making delicate instruments by skilled mechanics. After being made in the shop, all electrical and telegraph instruments are overhauled and adjusted.

Carpenters' Shop.—For pattern making, and making of cases and stands for instruments.

Switchboard Shop.—Mounting instruments and controlling gear on slate or marble frames for electric light stations.

Insulator and Battery Shop.—Porcelain insulators of all shapes and kinds. Galvanising stalks, brackets, &c. Galvanic batteries, wet and dry.

Cable Shop.—Making submarine cables. The core served with a covering of jute yarn passes from the small tanks into the rear of the sheathing machine, through the hollow axle of a circular frame carrying bobbins filled with steel wire; this frame revolves and lays the wires round the core without any twist; these are covered with alternate layers of compound and jute yarn, and pass finally to the tanks.

Cable Testing Room.—During the whole time of manufacture the cable is kept under electrical test to make sure that all is going right.

Cable Tanks.—In these the completed cable is stored under water until such time as it is delivered on board ship.

Lead Cable Shop.—Stranded copper conductors are covered with yarn, which is then thoroughly dried and soaked in a bituminous insulating compound. The covered wire is then passed up through a hydraulic press, which squeezes out a continuous lead pipe round it. The lead-cased cable is then further protected by iron armouring.

Wire Testing Room.—All wire delivered to the works is tested for strength and homogeneity.

Power Station.—The whole of the machinery throughout the works is driven by electric motors situated in the several shops. Here are collected the engines and dynamos for supplying the electric current, which is used also for lighting the shops and offices, being distributed to all parts by underground cables.

The total force represented in the electric department is estimated as about 1,200 horse-power.

PRESIDENT'S RECEPTION AND ANNUAL DINNER AT THE HOTEL CECIL.

At 7 p.m. the President held a Reception in the Drawing Room, after which, at 7.30 p.m., the members and guests dined in two large rooms, in one of which the chair was occupied by the President, in the other by Mr. B. E. R. Newlands (Chairman of the London Section).

After the usual loyal toasts, the healths of Prof. C. F. Chandler, Chairman-Elect of the New York Section, and Mr. B. E. R. Newlands, Chairman of the London Section, were proposed and drunk.

SMOKING CONCERT.

After dinner, the company adjourned to the Prince's Hall of the Hotel Cecil, where a Smoking Concert was held. An attractive programme of glees, songs, and recitations was provided, the artists being Mr. Edward Walford and the Guildhall Glee Singers (Messrs. Burford, Simmons, Williams, and Hinchliff); accompanist, Mr. R. W. Browne. Recitations were given by Messrs. Chas. Collette and E. J. O'Lea, and humorous speeches by Dr. J. Lewkowitsch and Mr. B. E. R. Newlands.

The toast, "Success to the Society of Chemical Industry," was proposed by the President during an interval, and was received with enthusiasm.

Mr. B. E. R. NEWLANDS proposed the "Health of the President," who, in briefly responding, desired the members, as the best thanks they could render him, to ponder well the grave issues he feared he had put before them in his address only too feebly; and next, to increase the value of the Society's Journal as a medium of technical information and the membership, so that the influence of the Society as a "power in the land" might become a great reality.

I.—PLANT, APPARATUS, AND MACHINERY.**PATENTS.***Evaporating, Condensing, and Cooling Fluids, Improved Method of and Apparatus for.* E. Theisen, Baden-Baden, Germany. Eng. Pat. 10,571, May 28, 1895.

INSTEAD of using a fan or similar device to secure the passage of air currents over the wet surfaces to be heated or cooled, the patentee forces the liquid through jets or nozzles placed centrally in tubes, whereby he claims that a rapid current of air is induced in the tube, "the frictional contact of which with the layer of liquid will produce an intense evaporative and cooling action."—O. H.

Evaporating, Condensing, and Cooling Fluids, Improvements in Apparatus for. E. Theisen, Baden-Baden, Germany. Eng. Pat. 4604, Feb. 29, 1896.

THE patentee describes several arrangements for the purposes set forth, the essential features of which consist in the delivery of the liquor under pressure, through reaction-nozzles on to the surface of a condenser; fan or propeller blades are attached to the nozzle pieces. The reaction causes the revolution of the fan blades with the nozzles, producing at the same time a current of air over the surface of the condenser, as well as spray of the liquid. See preceding patent.—O. H.

Cooling Apparatus for Liquids, Improvements in. H. Krack, Teplitz, Austria. Eng. Pat. 6749, March 27, 1896.

THE principle of the apparatus consists in the use of a series of flat tubes arranged in steps or terraces, and fixed on an adjustable inclined tray or support, at such an angle that the liquid to be cooled flows slowly over the cooling pipes: the upper and under surfaces of the pipes are always surrounded by liquid.—O. H.

Heating, Cooling, or Attenuating Water or Liquids, Improvements in Apparatus for. H. Prince, London. Eng. Pat. 8444, April 29, 1895.

THE apparatus described is practically an injector, fitted to steam and water supplies, so that by manipulating the steam or cold-water valves, steam alone, or water of any desired temperature, may be obtained.—O. H.

* Any of these specifications may be obtained by post by remitting 5s.—the price now fixed for all specifications, postage included—to Sir Henry Reader Lack, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C.

Filtering Material, Construction and Manufacture of; Improvements in. A. Smith, London. Eng. Pat. 11,973, June 5, 1895.

THE improvements consist in making filtering blocks or plates of coarse material and covering them with a thin coating of charcoal or other suitable material sufficiently fine to arrest any pathogenic or other germs that may be in the water filtered, thereby rendering such water sterile.

—O. H.

Basket or Packing Case, Improved, for Carboys of Acid and other Goods. C. Pottier, Paris. Eng. Pat. 11,405, June 11, 1895.

THE patentee claims "an improved basket or packing case for carboys of acid and other goods, consisting of the combination of an upper and lower ring of bent wood, uprights of flat iron or steel, intermediate rings of flat iron or steel, or of wood- or wicker-work, and a bottom of flat metal strips crossing each other, and having a central elastic guard."

—A. S.

Cooling Liquids, Improvements in Means for. H. Bamford, sen., S. B. Bamford, H. Bamford, jun., J. Bamford, Uttoxeter. Eng. Pat. 12,350, June 26, 1895.

THE object of this invention is to prevent the bulging which frequently takes place in the ordinary corrugated-plate refrigerator when any slight choking occurs.

To secure this end, suitable internal stiffening stays or strips of \sim -shape are fixed or soldered to the inside surfaces of the corrugated plates, so that when the plates are brought together and slid into position, the respective edges of the stays become locked together, thus holding the plates firmly.—O. H.

Sugar and like Substances, Melting of; Improvements in and relating to Machinery for. M. Blake, Greenock. Eng. Pat. 12,362, June 26, 1895.

THE apparatus essentially consists of a long cylindrical vessel running on rollers, and which may be either slightly inclined or horizontal. The rollers are connected to suitable gearing, and a slow rotatory motion is imparted to the cylinder. The inside of the vessel is fitted with blades, which may vary in size and disposition. The charging end is fitted with a stuffing box and gland which rotates with the machine, and works into a trunnion piece, bolted on to the bend and bracket forming part of the hopper. At the discharging end, a similar stuffing box and gland with a fixed trunnion siphon pipe is provided, so that in continuous working there is no obstruction to the charging or discharging of the apparatus. The claim is for "rotary acting machines for melting sugar and the like."—J. L. B.

Liquefying Gases or Gaseous Mixtures, and for Producing Cold, more particularly applicable for separating Oxygen from Atmospheric Air; Process and Apparatus for. C. Lände, Munich, Bavaria. Eng. Pat. 12,528, June 28, 1895.

THIS process consists essentially in allowing the gas or gaseous mixture to expand so as to produce a lower temperature, the amount of cooling being in accordance (Centigrade degrees) with the following equation:—

$$\delta = 0.276 (p^2 - p^1) \left(\frac{273}{T} \right)^2,$$

where $p^2 - p^1$ indicates the difference of pressure, and T the absolute temperature of the outflow. The invention is particularly described in connection with separating oxygen from atmospheric air, in which case the air, say at pressure (p^2) and temperature (T^2), is compressed by a pump to $p^1 T^1$, and thence passes to the main compressor, where it is raised to $p^2 T^2$. From here it passes to a cooling apparatus, which it leaves at $p^2 T^3$, and passes to a junction, from which the main current passes to a heat exchanger. This consists of a helical tube arranged within a larger helical tube through which cooled gas passes in the reverse direction. Leaving this at $p^2 T^4$, the air passes through a constricted orifice into a chamber, where it expands to p^1 , and is proportionately reduced in temperature to T^5 . The cooled expanded air passes out to the outer coil of the heat

exchanger above, thus further reducing the temperature of the incoming air, and is led back to the main compressor. After a time, some of the air in the expansion chamber liquefies and collects at the bottom thereof, the uncondensed portion passing back as before. This liquid air is drawn off through a tube having a regulating valve, into a vessel having a lower pressure p^3 , whereby a portion of the liquid, namely, the nitrogen or a part thereof, evaporates. In this vessel is arranged a coiled pipe through which some of the air at $p^2 T^5$ is led from the before-mentioned junction, whereby further nitrogen is evaporated, and practically pure liquid oxygen remains, which may be withdrawn for any desired use. The evaporated nitrogen gas passes through the outer coil of a reversed-flow heat exchanger similar to the one above mentioned, through which the air used in the last vessel passes on its way from the junction. The nitrogen then escapes. If the oxygen be required in the gaseous form, it is allowed to overflow from the vessel wherein it is collected in the pure state to a third heat exchanger, through which a portion of the air at $p^2 T^5$ from the junction may be led, whereby the latter is cooled to T^6 and is then led to the inlet of the expansion vessel, while the oxygen evaporates. Drawings are given of two modified forms of the actual apparatus employed. The whole apparatus must be perfectly enclosed in a good isolating medium, without any parts of it, either fixed or moving, being exposed to atmospheric temperature; while the internal parts which move by friction must not be subject to the low temperatures required for liquefying the air. The heat exchangers may be formed of long metal channels instead of tubes.—R. S.

Filtering Apparatus, Improvements in and relating to. H. J. E. Jensen, Hamburg, Germany. Eng. Pat. 12,597, June 29, 1895.

THIS filtering apparatus, intended for filtering wine, beer, and the like, is constructed with an upper distributing chamber contracted somewhat at its lower part, and carrying therefrom a perforated surface or wire-gauze sieve lined internally with asbestos or similar filtering fibres, and having a solid bottom. The filtered liquid passes into an outer cylindrical receiver provided with a draw-off cock. The upper distributing chamber has a central supply funnel, the tubular lower portion of which is either perforated, whilst its bottom is covered with a metal plate, or the tube is unperforated and the metal plate arranged so as to leave a space all around, between it and the lower end of the tube. The supply of liquid to the funnel is regulated by a ball valve, having a stationary slotted plug and a movable casing, to which is attached the pipe carrying the ball. The pipe is extended downwards by two arms or branches which dip into the liquid in the funnel.—R. S.

Superheated Steam, Improvements in the Method of and Apparatus for the Production of. F. Bornmann-Zix, Zürich, Switzerland. Eng. Pat. 13,896, July 20, 1895.

THIS apparatus consists of a vertical cylindrical casing, in the bottom of which is a reservoir, above that a furnace, and above the latter a central steam producer surrounded by a superheating coil. The reservoir has two charging pipes, for air and water respectively, leading from suitable forcing apparatus, and two discharge tubes, one at the bottom for water and the other at the top for air. These tubes pass, one each side of the apparatus, up to a disperser or spray producer arranged immediately above the top of the apparatus, whereby a fine spray is introduced into the steam producer. By means of the furnace below, steam is produced, and led by a tube from the centre of the bottom of the producer on one side and into the top of the superheating coil outside. From the latter the superheated steam passes up a vertical pipe to the outlet.—R. S.

Soap and other like Plastic Substances, Improvements in the Kneading and Moulding of, and in Apparatus therefor. W. P. Thompson, Liverpool. From A. and E. des Cressonnières, Brussels. Eng. Pat. 19,960, Oct. 23, 1895.

TO obviate irregularity of working and lack of uniformity of composition of the material kneaded or moulded, an ordinary kneading apparatus is connected with one in

which combined feeding and squeezing are effected. The cylinders of the former are arranged in a lateral opening of the drum, parallel to the axis of the screw conveyor, whilst the knives or scrapers are fixed in such a way that the scrapings fall between the blades of the screw conveyor, and are immediately carried forward to the mould. It is claimed that by this process no irregularity in kneading can occur, and that the quantity of material introduced can be exactly regulated.—C. A. M.

Heating or Cooling Agent [Glycerin], New or Improved. A. J. Boulton, London. From M. W. Judell, Petersburg, South Australia. Eng. Pat. 3575, Feb. 17, 1896.

GLYCERIN or its allied products, either alone or mixed with water, is used as a heating or cooling agent in jackets, chambers, pipes, and the like. A number of applications are mentioned, but the invention is generally applicable.—R. S.

Furnaces, Improvements in. W. R. Jones, Rome, Italy. Eng. Pat. 7878, April 14, 1896.

THE invention primarily relates to furnaces for heating gas retorts. The sides and back of the furnace are built with a smooth surface and inclined towards the centre in order that the clinker may slide down easily. Along the centre of the bottom of the furnace the bricks do not meet, leaving a slit. The primary air is drawn through flues situated on either side of this slit, and the secondary air through movable fire-clay or iron tubes, which may be situated in the retort flues or below them, and communicate with flues in the setting, through which the air is delivered into the retort flues. Cold air may be substituted for the heated air supply, in which case it is admitted below the slit, a screen or wind-guard being provided to prevent a too sudden in-rush of air.—A. G. R.

Superheating Steam, Improved Apparatus for. B. Jaßé, Charlottenburg, Germany. Eng. Pat. 8112, April 17, 1896.

THE apparatus consists of one or more tubes, preferably vertical, containing within each of them a helical blade, which forms, together with the inner surface of the tube, a helical passage. Where more than one tube is employed, they are connected together by external bends. The tubes are exposed outside to the action of the flames and combustion gases, whilst the steam passes through them. In consequence of the helical blades, the steam is retained for a very considerable time, in comparison with the length of the tubes, in contact therewith.—R. S.

II.—FUEL, GAS, AND LIGHT.

Mond Producer-Gas applied to the Manufacture of Steel. J. H. Darby, Iron and Steel Inst., Spring Meeting, 1896. The Ironmonger, 282—286.

IN his presidential address to the Society of Chemical Industry in 1889, Ludwig Mond made public his process for the manufacture of producer-gas with the recovery of sulphate of ammonia (this Journal, 1894, 938—939). The present author deals with this process and its improvements, and then gives details and results of the practical application of this gas to the manufacture of steel.

When fuel is gasified in the ordinary producer, the products of distillation, including tar, first leave the fuel, and the fixed carbon is ultimately converted into carbon monoxide. This raises the temperature of the contents of the producer and of the resulting gas to a high degree, and is sufficient to decompose most of the ammonia which was originally present in the fuel as nitrogen, as well as to effect a distillation of the volatile products. The objects which Mond wished to attain in his producer plant, were to utilise the heat developed by the combustion of carbon monoxide, by transferring the sensible heat in the steam and gas leaving the producer, to the air and steam entering the producer. In this way he was enabled to use far more steam than is generally employed, and to work with a low temperature in the producer, thus preventing the decom-

position of the ammonia. This enabled him to obtain the enormous yield of nearly 100 lb. of sulphate per ton of fuel, at the same time producing a much larger volume of gas of about the same calorific value, volume for volume, compared with ordinary producer-gas. When he introduced, together with superheated air required to burn the fuel in the producer, $2\frac{1}{2}$ tons of steam for every ton of fuel consumed, he found that over 70 per cent. of the total nitrogen in the coal could be recovered in the form of sulphate of ammonia from the producer-gases. Only about one-third of the steam introduced into the producer is decomposed in its passage through the fuel, so that two thirds remain in the gases, leaving the producer at a temperature of 450 to 500 °C. The problem was to return this steam, or its equivalent, to the producer, and to transfer the initial heat in the gas and steam leaving, to the air and steam entering the producer for the combustion of the fuel.

The gas leaving the producer from one ton of coal is about 160,000 cu. ft., and mixed with this gas is steam to the amount of 100,000 cu. ft. The difficulty of providing suitable cooling arrangements for this heavy ratio of steam is solved by Mond as follows:—The hot producer-gas is passed through a series of pipes surrounded by an annular space, through which the mixture of air and steam to be introduced into the producer is led in an opposite direction, thus taking up the heat from the hot gas and becoming superheated. Thence the producer-gas is led through a rectangular chamber partly filled with water, which is thrown up in a fine spray by revolving beaters, so as to fill the whole area of the chamber. This water becomes hot, a certain quantity of it evaporates, and the spray produced washes all the dust and soot out of the gases. From this chamber the gas, which is now cooled down to about 100 °C., and is charged with a large amount of water vapour, is passed through a leaden scrubber filled with perforated bricks in which the ammonia contained in the gas is absorbed by dilute sulphuric acid. In this scrubber a fairly concentrated solution of sulphate of ammonia, containing 36 to 38 per cent., is used, to which a small quantity of sulphuric acid is added, so that the liquid leaving the scrubber contains only 2.5 per cent. of free acid. This liquid passes through a separator, in which it is clarified. The greater portion of the clear liquid is, after the addition of a fresh quantity of acid, pumped back to the scrubber. The remaining portion of the liquid is withdrawn and evaporated by steam coils in lead-lined pans, which are kept constantly filled by the addition of fresh liquor until the whole mass is thick. This is run out on a strainer, and yields, after draining, a sulphate of ammonia of very fair quality and up to the market strength of 24 per cent. of ammonia. The mother-liquor is pumped back to the scrubber. The gas, on entering the scrubber, contains only 0.13 volume per cent. of ammonia, and, on leaving, less than one-tenth of this quantity.

The gas next passes through a second scrubber, where it meets with a current of cold water passing over perforated wood blocks, which condenses the water vapour, the water itself being thereby heated. The gas is cooled down from 80 to about 50 °C. in this scrubber, whence it passes to the gas main for consumption. The hot water is pumped through a third scrubber, through which, in an opposite direction, cold air is forced previous to entering the producer. The air thus gets heated to about 74° C. and becomes saturated with moisture at that temperature, whilst the water is rendered cold enough to be pumped back through the second scrubber. The same water is thus constantly used for condensing the water vapour in one scrubber and giving it up to the air in the other. In this way about one-half of the steam required for the producer is recovered, and returned to the producer. The rest of the steam required is in part obtained as exhaust steam from the engines driving the blowers and pumps, and the remainder, wherever possible, from any other available exhaust.

On removing the plugs at the bottom of the tubes leading the gas from the producer to the mechanical washer, nothing but dust issues with the gases, showing that in

this process the gas, although washed, does not lose its tarry products, but retains them as permanent gas. The labour item in connection with this producer is very small. Repairs, owing to the low temperature at which it works, are nominal. The quantity of fuel gasified per producer for 24 hours is 20 to 22 tons. The gas contains on an average by volume, carbon dioxide, 17.1; carbon monoxide, 11.0; olefines, 0.4; methane, 1.8; hydrogen, 27.2; and nitrogen, 42.5 per cent. The total combustible gas equals 49.4 per cent, giving about 1,350 K.C. cals.

The calorific value of this gas per unit of weight of fuel gasified, is higher than that of ordinary producer-gas, and is equal to 80 per cent. of the calorific value of the fuel used, instead of about 60 to 65, as in the ordinary producer. The plant may be worked in two ways—either with recovery of sulphate of ammonia or without.

Owing to the general belief that washed gas was not satisfactory in the manufacture of steel, Mond erected a three-ton furnace to ascertain whether he could obtain the high temperatures required, quickly and efficiently. No trouble whatever was found with using the washed gas, the furnace working three charges in less than 24 hours. The average analysis of nine casts gave the following results:—Carbon, 0.240; silicon, 0.038; sulphur, 0.039; phosphorus, 0.037; and manganese, 0.457 per cent. The mechanical tests of 12 samples containing 0.16 to 0.22 per cent. of carbon showed a tensile strength of from 25.2 to 27.6 tons per square inch, with from 32 to 36 per cent. elongation.

One of the points of difference observed by the author between the Mond gas in the steel furnace and the ordinary producer-gas, was the considerable length of the flame. With a fair-sized furnace the gas was able to thoroughly expend itself and to keep the steel at a satisfactory temperature during the whole operation with apparently a very small consumption of gas.—A. W.

Nitrogen and Nitrogen Compounds from the Distillation of Coal. J. Lundin. Teknisk Forenings Tidskrift, 1892, 22, 21–25.

The author describes experiments made by Knublauch, and others by himself, chiefly on Westphalian coals; other coals show a different behaviour. The following are the conclusions arrived at:—(1.) About 50 per cent. of the nitrogen remains in the coke. (2.) About 30 per cent. of the nitrogen appears in the gas; it is objectionable on account of its deteriorating influence on the light given thereby. (3.) 12–14 per cent. of the nitrogen is converted into ammonia, this quantity corresponding with 10.4 kilos. of ammonia per ton of coal. (4.) Barely 2 per cent. of the nitrogen, *i.e.*, 0.02 per cent. of the weight of the coal, appears as cyanide, corresponding to 1.4 kilo. of potassium ferrocyanide per ton of coal; two-thirds of this quantity is retained by the purifying material. (5.) $\frac{1}{2}$ per cent. of the nitrogen is found as bases in the tar. At the most 0.2–0.25 per cent. of nitrogen in the coal is recovered in a marketable form, the quantity lost representing (at present prices) a loss of 10,000 marks per million cubic metres of gas.—B. B.

Acetylene, Products of Combustion of. N. Gréchant. Comptes rend. 1896, 122, 832.

A "MANCHESTER" burner, with which acetylene was burnt, was placed under a metal cylinder so that the products of combustion could be drawn over into a gas-holder and examined. The ratio between the volume of carbon dioxide formed and of oxygen used was 0.82, that calculated on the supposition that the acetylene underwent complete combustion being 0.8. Further tests, both chemical and physiological, failed to reveal the presence in the products of combustion of the smallest trace of any combustible gases containing carbon.

The author finds that among the various explosive mixtures of air and acetylene, that containing 1 volume of acetylene to 9 of air explodes with the greatest violence.

—T. E.

Acetylene, Action of, upon Iron, Nickel, and Cobalt reduced by Hydrogen. H. Moissan and Ch. Moreau. Comptes rend. 122, 1240–1243.

Iron, nickel, and cobalt which have been reduced by hydrogen at the lowest possible temperatures, reduce acetylene in the cold with incandescence, forming hydrogen and metallic carbides. The decomposition is due to the porosity of the metals, and takes place also with platinum black.—V. C.

Incandescent Alcohol Lamps for Street Lighting. Zeits. f. Spiritusind. 1896, 19, 143.

The question of the employment of alcohol for illuminating purposes is being investigated in Germany, and the owners of a number of distilleries are undertaking the lighting of small towns in their neighbourhood by means of incandescent spirit lamps. In a town in Saxony, a trial is said to have already been made in the market place, whilst a distiller in East Prussia states that he has undertaken to light the neighbouring town at the same cost as the petroleum lighting hitherto in use.—A. PATENTS.

Coke Manufacture, Construction of Coke Ovens, and Recovery of By-Products from same; An Improved System for. J. T. Key, Royston, Yorkshire, and W. S. Key, Winthrop, Mass., U.S.A. Eng. Pat. 10,356, May 27, 1895.

BEEHIVE coke ovens with false bottoms, and with channels down which the by-products can flow into the main. This main opens under the centre of the false bottom, and is furnished with a number of subsidiary mains, radiating from it, so that the products may be drawn off by an exhauster uniformly. Air enters through an annular flue surrounding the top of the oven. Thus, the air drawn in is evenly distributed over the coke, so that it is claimed, a more consolidated product and a higher yield than that got by other systems is obtained. The coke is quenched *in situ* by the admission of steam through pipes opening under the false bottom; this is said to effect desulphurisation.—A. G. B.

Incandescent Gas Burners, Improvements in. J. H. W. Stringfellow, Hackney. Eng. Pat. 16,743, May 30, 1895.

The inventor proposes to utilise a foundation of natural or artificial meerschaum or other similar bodies having the requisite lightness, coherence, and slow conduction, coating this with a material or materials capable of becoming incandescent, such as certain metallic oxides, asbestos, &c., either by cementing or otherwise, the body thus prepared being suspended in a non-luminous flame or in the non-luminous face of an illuminating flame.—C. S.

Gaslight, Improvements in Glowing Nets [Mantles] for. H. Burkert and R. Seemann, Berlin. Eng. Pat. 3262, Feb. 13, 1896.

The improvement claimed is the employment of a mixture of thorium (in the form of nitrate) with an element of the chrome group, preferably uranium—1 per cent. of the oxide

of uranium developing the incandescent power of the thorium—without using magnesia, zirconium, or the cerium group.—C. S.

Incandescent Gas and Oil Lamps, Improvements in Mantles for. J. P. de Liéry, New York, U.S.A. Eng. Pat. 7429, April 8, 1896.

NITROCELLULOSE is dissolved, preferably by glacial acetic acid or other solvent capable of dissolving the salts or oxides suitable for producing incandescence (such as are derived from monazite sands), to a thick paste or jelly, along with the said oxides, &c., and formed into threads, which are washed and de-nitrified in the usual manner, operating preferably by alkalis in a neutral solution. The material is finally manufactured into mantles in the ordinary way. Increased durability and greater capacity to withstand wear and tear is claimed for mantles thus prepared.—C. S.

Acetylene Gas, Improvements in Apparatus for Generating. J. H. Exley, Huddersfield. Eng. Pat. 12,344, June 26, 1895.

THIS consists of a vertical receiver with a cistern on the top, which latter delivers water by a pipe opening near the bottom of the receiver. One or two external cylindrical generators are placed outside and close to the receiver, and are connected with the same by two pipes, one near the top of the generator and receiver, to admit the acetylene gas; the other near the bottom of the receiver and generator, for the passage of the water. The apparatus is intended to work automatically on the principle of the well-known Kipp's generator.—L. T. T.

Acetylene Gas Lamps, An Improved Generator for. R. Campe, Berlin. Eng. Pat. 16,691, Sept. 6, 1895.

THE calcium carbide (in a finely powdered condition) is contained in a funnel-shaped vessel, the small opening at the bottom of which is closed by a milled or grooved cylinder rotated by clockwork. In rotating, this cylinder carries down a little of the carbide into a small chamber below. This second chamber is closed by a slide-valve, actuated by a rod having a handle outside the generator. When this valve is opened, the clockwork is released and the carbide is slowly dropped into water in a vessel situated below the valve. If the carbide be released too rapidly by the grooved cylinder, the small chamber below becomes filled, and so retards the action of the cylinder. In closing the valve, this stops the clockwork by coming against a stop-pin in the cylinder shaft. The speed of generation can be regulated by the degree to which the slide-valve is opened.—L. T. T.

Acetylene Gas, An Improved Apparatus for Generating, Storing, and Purifying. J. C. Bayley, Bournemouth. Eng. Pat. 322, Jan. 6, 1896.

A VESSEL containing water is provided, inside which a float is inserted through an opening in the top, which can be closed so as to be air-tight. This float has its sides perforated, and serves as a receptacle for the carbide. The float is free to rise and fall in the water between vertical guides. Water rises in an annular space in this float, which is packed with porous material, percolates the material, and then comes in contact with the carbide. If the generation of gas be more rapid than its consumption, the pressure of the gas presses down the water in the annular space, and so removes it from contact with the carbide. An automatically regulated supply of gas is thus obtained.—L. T. T.

Acetylene Gas, Improvements in the Production and Utilisation for Lighting. G. Ragot, Forest-lez-Bruxelles, Belgium. Eng. Pat. 5279, March 9, 1896.

THIS is an automatic apparatus, the admission of water from a reservoir to the generator filled with calcium carbide—or, conversely, of carbide to the generator filled with water—being regulated by the descent of the gasometer, which causes the flexible outflow pipe to deflect and deliver into

the supply pipe leading to the generator. A mercury seal in this supply pipe prevents the access of moisture to the carbide except when the water is turned on. The generator consists of two cylinders, and, when the carbide in one is exhausted, the descent of the gasometer causes an affixed tappet to engage with a pawl attached to a tap on the supply pipe, thereby opening a branch pipe and delivering water to the second cylinder. A reducer, similar to that employed for utilising rich gases in railway carriages, is attached, for regulating the pressure to the burners. These latter consist of a couple of converging jets about an inch apart, thus allowing a suitable commingling of air with the two jets of gas on the way to the (vertical) flame, and utilising the illuminating power of the gas to its fullest extent.—C. S.

Acetylene, Method of and Apparatus for Generating. W. C. Clarke, New York, U.S.A. Eng. Pat. 7242, April 2, 1896.

THIS apparatus consists of a holder connected with two or more generators of such a size as each to contain a charge of calcium carbide less than sufficient to fill the holder. Each generator has a tank of a size to hold the requisite quantity of water for a charge, and the pipe leading from the tank to the generator is controlled by a valve, the arm of which is so weighted and arranged that on being slightly depressed by a projecting arm on the descending holder, it is at once fully opened, and discharges the full quantity of water requisite for the charge. By multiplying the number of generators and arranging the actuating arms at slightly different heights on the holder, the different generators can be successively brought into operation and a continuous supply of gas automatically maintained for any desired time.—L. T. T.

Illuminating Gas [Acetylene], Method of Generating. W. C. Clarke, New York, U.S.A. Eng. Pat. 7243, April 2, 1896.

THIS apparatus is similar in construction to that of the preceding patent, except that in this case larger generators are used, and the water-supply valve on each is so weighted that when depressed by one of the arms projecting from the holder, a little water only is admitted to the generator. On the pressure being removed by the rise of the holder, the weighted valve shuts off the water supply, only to be opened again on the next fall of the holder. In this way an intermittent supply of water is fed into the generator till all the carbide is used up, when the next generator is brought into action.—L. T. T.

[Acetylene] Gas, Improvements relating to the Generation of, and to Apparatus therefor. E. T. Turney, Chicago, U.S. Eng. Pat. 5375 (under Internat. Convention), March 10, 1896.

THE essential part of this generator consists of a small cylinder containing a rod of solid or compressed calcium carbide (or other similar material), moving easily therein. One end of the cylinder is closed by a screw cap (for introducing the rod of carbide), and to this is attached a coiled spring to push forward the carbide rod. Surrounding the other end of the tube is an elastic ring or collar, the diameter of which, when not stretched, is less than that of the tube, so that when arranged thereon with a portion projecting beyond the end of the tube, this projecting portion will form an elastic lip which has a constant tendency to contract. When the carbide rod (which must be of greater diameter than the elastic lip) is pushed through the elastic ring, the latter forms a liquid-tight joint around the rod. The cylinder projects into a closed generating vessel containing, preferably, very dilute methyl alcohol to moderate the violence of the action. In this vessel a stop is arranged to prevent the carbide rod being pushed through the elastic ring beyond a suitable and very short distance. In this way a constant and definite surface of carbide is exposed to the active liquid, and thus a constant and regular generation of gas is maintained.—L. T. T.

[Acetylene] Gas, Improvements in Apparatus for the Manufacture of. E. Farnsworth, Minneapolis, U.S. Eng. Pat. 5624 (under Internat. Convention). March 12, 1896.

In this apparatus the essential novelty consists in attaching the calcium carbide receptacle to the top of the movable or telescoping gas-holder, so that the filling of the holder, automatically and bodily lifts the carbide receptacle out of the water. Through the centre of the top of the holder passes a tube (fitted with an air-tight screw cover) projecting about half the depth of the well. Inside this is a closely fitting hollow piston, fitted with an air-tight screwed cover, and packed so as to make an air tight but movable joint. From the bottom of this piston hangs the perforated receptacle filled with carbide. Generation of gas immediately commences when the holder is low in the water, and consequently little gas is present, and continues till, on rising, it lifts the carbide receptacle out of the water.

—L. T. T.

Gas, Freezing of, in Gas Mains, Improvements in Preventing the, and Apparatus therefor and for Carburetted Gas The Whessoe Foundry Company, Limited, Darlington, Durham. From The Berlin Anhaltische Maschinenbau-Aktiengesellschaft, Martinikendorf, Berlin, Germany. Eng. Pat. 882, Jan. 13, 1896.

By mixing vapour of alcohol with gas, the "freezing point" of the gas (temperature at which it deposits naphthalene) is so lowered that even in the coldest weather stoppage of the pipes will be prevented. The apparatus designed for the application of this discovery consists of a receiver for holding the spirit, into which the latter is advantageously introduced by hydraulic pressure; by dividing this receiver into an upper and a lower chamber connected by a suitable arrangement of pipes, regularity of flow of the spirit from the receiver to the vaporiser, described hereinafter, is secured; and by admitting gas instead of air to take the place of the spirit withdrawn, loss by evaporation is avoided. The receiver is connected, by means of a regulating valve, with a vaporiser, in which the spirit flows down inclined floors provided with corrugations to increase the surface; steam or hot water is admitted beneath these floors and is caused to travel in the same direction as that of the spirit. When it is merely desired to prevent the "freezing" of gas, the spirit may be allowed to flow directly into the main, when it will mix with the gas by its own tension. The whole apparatus, however, is also designed for carburetting gas with benzene, petroleum spirit, or other light hydrocarbon, in which case the vaporiser is brought into play in the manner described.—A. G. B.

Gas Generator, A Self-regulating. S. S. Bromhead, London. From A. Niel, Evreux, France. Eng. Pat. 4574, March 2, 1896.

THE claim is for a generator for the manufacture of water-gas. It consists of a double cylindrical casing V, of which the interior cylindrical space is the furnace of the gas generator for containing the burning coal. In passing through this, the mixture of steam and air is decomposed, thereby forming the combustible gas. The furnace is lined with fire bricks *i*, and at its upper end is placed the vaporising chamber Y, arranged so that its lower side is heated by the gases leaving the furnace through the pipes H. A feed-tunnel R, furnished with a cover T, is arranged above the central part of the boiler, which forms the upper part of the furnace, and communication is effected between the two by means of the cone S, which is operated from the outside by means of a lever. The feed-funnel may be moved as indicated by the dotted lines, by means of the lever U.

The water enters the boiler through the pipe P, and its height is kept constant, automatically, by means of the float *j*, acting in conjunction with a cock in the pipe P. The flow of water is regulated so as to obtain only a thin layer upon the highest part of the lower side of the boiler. Air is supplied by a pump, and is conducted through the pipe A into the space formed by the double casing of the furnace, where it is heated by contact with the sides of the furnace and the pipes I J. It then passes through the pipe B,

through the self-regulating valve C, and through the pipe D, into the boiler Y, where it passes over the surface of the hot water and helps to vaporise it. The air thus saturated, with steam descends through the pipes E F into the closed

furnace, and is converted into the water-gas by passing through the mass of burning fuel G. The gas leaves the furnace through the pipes H, and, descending through the pipes I J into the space X, passes through the pipe K on to the washer.

The washer, wherein the gases are washed by means of a column of coke kept moist by water, and also, if necessary, by a stratum of sawdust, the self-regulating valve, and the feed pump which supplies the air, are described and illustrated.—A. S.

Regenerative Furnaces, Improvements in, and in the Method of Operating the same. S. Pitt, Sutton, Surrey. From H. L. Gantt, Norristown, Montgomery, Pennsylvania, U.S.A. Eng. Pat. 8065, April 16, 1896.

THE figure represents a vertical section of the furnace.

A is the hearth, access to which is obtained through the opening A¹ when the slide B is withdrawn. The material to be heated is charged through the chamber C, covered by the cap C¹, and is removed through an opening situated at A². D and D¹ are fuel chambers communicating with the hearth by the flues D², D³, and with the regenerators E and E¹, by the flues E² and E³. The chequer-work E⁴ is of the usual material.

Behind the regenerators E and E¹ are two other chequer chambers, communicating with E and E¹ by the flues G² and G³. At the upper ends of these rear chambers are flues communicating with the outer air and furnished with fans for causing a draught. In working the furnace, chamber D¹ is filled with incandescent fuel, and air is forced by the fan down the chamber in the rear of regenerator E¹, up this regenerator, and through the fuel in D¹, which burns to carbon monoxide. The products of combustion pass through the fuel in D, which is thus heated up, and down regenerator E; here

the carbon monoxide burns in that portion of the air which finds its way through the flue F from E' to E. This combustion heats the regenerator as well as the rear chamber

up which the products of combustion must pass, by way of G², into the outer air. A reversal of the fan will obviously reverse the course of the air and products of combustion. Since hot carbon monoxide and nitrogen alone pass into the hearth, the action on the material to be heated, is a highly reducing one.—A. G. B.

Burners and Vaporisers for Liquid Combustibles, Improvements in. L. Runge, Berlin. Eng. Pat. 8151, April 17, 1896.

In this burner the liquid is introduced into a vaporising cylinder, the vapour being conveyed down to the burner-foot, where it issues from a central jet and re-ascends within a cylindrical mixing chamber to the incandescent body. The latter is held in position by uprights attached to a ring encircling the vaporising cylinder and forming part of a cap which surrounds the upper extremity of the mixing cylinder and carries the burner gallery, the head of the cap being perforated to allow the mixed vapour to rise to the flame.—C. S.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

Petroleum Industry of the District of Ter. K. J. Tumsky. Trudy bak. otd. imp. russk. tehn. obschtsch. 1896, 11, 80.

This district was the first to be worked for petroleum in Russia, refineries being erected at Mosdok. Oil was discovered in the Grosney field in 1833, but was only obtained in small quantities and from a few shallow wells. On boring deeper the yield was, however, increased, the most productive well being that bored by the Stuart Company in 1895, which spouted to a height of 100 metres, and yielded during the first few days about 800,000 poods per diem.

The Grosney oil contains about 15 per cent. of petroleum spirit, but comparatively little burning oil. The residue, amounting to about 55 per cent., has a specific gravity of about 0.960 and flashes at 120 to 130° C. As a lubricating oil it was preferred to Baku residuum, but is too thick to spray for fuel, and the crude oil is too inflammable,

so that the refiners simply distil off the spirit and sell the remainder for heating purposes, now that petroleum is cheap and the demand for lubricating oils insufficient.—C. S.

Petroleum Naphtha, The Production of Bitumen and Tar from. Kouindjy. Bull. de la Soc. d'encouragement pour l'industrie nationale, 94, 1116—1119.

With the object of producing from the petroleum residues certain substances hitherto largely obtained from coal—*viz.*, bitumen, tar, and hydrocarbons of the aromatic series without the production of coke—M. Adiassewitch has devised a process in which the residues are distilled at a temperature of 150°—200° C. Meanwhile hot air is blown into the heated mass, and an electric current caused to pass through it. After four hours' heating, the residue consists of a bitumen of density 1, the yield being 95 per cent. of the original weight, and after eight hours a solid bitumen is obtained of density 1.04, with a yield of 85 per cent. This product contains no coke, and is perfectly soluble in petroleum spirit.

A similar bitumen results from suitable treatment of the "mineral naphtha" found as a deposit in the district of Harie, in the Caucasus. This mineral contains 5 to 35 per cent. of bitumen, soluble in CS₂, which Adiassewitch separates from the mineral by disintegrating the latter in a vessel of special construction, furnished with revolving knives and screws, and filled with boiling water. The bitumen floats on the surface, whence it is drawn off into settling tanks to free it from sand and water, and is subsequently concentrated to a density slightly above 1.

This bitumen may be fractionated by distillation by means of superheated steam, or may be subjected to the treatment already described for acid residues. By the former process 50 per cent. of oils of sp. gr. 0.926—0.972 are obtained, and a tarry residue remains, containing 10 per cent. of coke. If, however, the method of Adiassewitch be employed, a series of tars, it is said, from the condition of liquid to that of solid, result (sp. gr. 1.005—1.06). All these products are soluble in petroleum spirit, CS₂, &c. Their chief uses are in the manufacture of asphalt, for railway sleepers, &c.—R. B. B.

American Petroleum, Investigations on. Chemistry of the Berea Grit Petroleum. C. F. Mabery and O. C. Dunn. Amer. Chem. J. 18, 215—236.

THE composition of the oil from the Berea grit of Ohio and the adjoining States has not hitherto been investigated. As a result of their examination of a number of oils from various depths of strata, the authors find that Engler's conclusion that the specific gravity of petroleum varies inversely with the depth of the well, is not supported in the case of the sand-stone oils of Southern Ohio, the oil from the 500-ft. sand being nearly as light (sp. gr. 0.7971) as that from the 1,500-ft. sand of the Berea grit (0.7939). The latter sand also contains the heaviest oil of all (0.8274). The proportion of nitrogen appears in most instances to increase with the depth of the well.

In consequence of the difficulty in the way of procuring a sufficient quantity of the lighter fractions of distillate, attention was concentrated on the less volatile portions. The lowest fraction examined was that boiling at 159°—160° C., and this yielded, after repeated re-distillations, a hydrocarbon of sp. gr. 0.7629, boiling constantly at 162°—163°, and containing 85.25 per cent. of carbon and 14.53 of hydrogen (the "decane" of Pelouze and Cahours boiled at 161°—162°). After purification, the distillate had a sp. gr. of 0.7475.

The next distillate of importance came over between 168° and 173°, the boiling point on re-distillation being finally 174°—175°.—C. S.

PATENT.

Oils [Petroleum], Improvement in Refining. J. Y. Johnson, London. From The Ohio Oil Improvement Company, Cleveland, Ohio, U.S.A. Eng. Pat. 8348, April 21, 1896.

THE process is designed principally for removing the sulphur from "sulphur petroleum," and consists in

allowing the crude petroleum distillate to flow slowly between, or remain in contact with, plates or sheets of lead and carbon, placed in close proximity to one another, but not touching. The nature of the reaction that occurs is not yet definitely ascertained, but the result produced is that the clear oil turns dark red, becoming nearly opaque, and when subsequently refined by the ordinary acid treatment, deposits a whitish powder, difficult to analyse, but apparently containing the sulphur impurities. The lead appears to be the active agent, although it is not corroded, but the carbon seems to be essential to the completeness of the reaction. The carbon plates must be clean. At the outset, longer contact is necessary to effect the reaction than is subsequently required. The time of exposure varies with the oil, half an hour being usually sufficient for Lima oil. By discharging the oil into a vessel containing water, some of the impurities may be removed before applying the "acid treatment."—C. S.

IV.—COLOURING MATTERS AND DYES.

Dinitronaphthalene-1:8. C. Gassmann. *Comptes rend.* 1896, **122**, 937—939.

The author finds that the proportion of the 1:8 product is increased by using strong acids in nitrating, and by not cooling. The best results were obtained as follows:—A mixture was made of 260 grms. of 61·7 per cent. nitric acid, 200 grms. of 92 per cent. sulphuric acid, and 200 grms. of 60 per cent. sulphuric anhydride. 128 grms. of naphthalene were then gradually added without cooling, and when all the naphthalene had been added, the whole was heated for 10 hours on the water-bath, allowed to cool, and poured into 5 litres of cold water. 215 grms. of crude product (98·6 per cent. of theory) were obtained, which yielded 148 grms. of 1:8-dinitronaphthalene and 52 grms. of the 1:5 isomeride.—L. T. T.

Anisol, Iodo Derivatives of. F. Reverdin. *Ber.* 1896, **29**, 997—1005.

o-Iodo-anisol, $C_6H_4(OCH_3)I$, prepared by the action of potassium iodide on diazotised *o*-anisidine. Best isolated by steam distillation in presence of SO_2 . *o*-Iodo-anisol is a heavy oil, sp. gr. 1·8, boiling at 239° — $240^{\circ}C$, under 730 mm. pressure.

o-Iodo-p-nitro-anisol, $C_6H_3(OCH_3)I.NO_2$ [1:2:4], obtained by nitration, at a low temperature, of the preceding compound.

o-Iodo-p-anisidine, $C_6H_3(OCH_3)I.NH_2$ [1:2:4], obtained by reducing the above nitro body with stannous chloride and hydrochloric acid, is soluble in much boiling water, from which it separates, on cooling, in fine, white needles, melting at 74° — $75^{\circ}C$. It is volatile with steam. Its diazo derivative yields with naphthol sulphonic acid ($OH:HSO_3 = 1:1$), a red dye resembling that obtained similarly from *p*-anisidine.

Di-iodo-anisol, $C_6H_3(OCH_3)I_2$ [1:2:4].—The above iodo-anisidine is diazotised in presence of potassium iodide. The new compound separates in the shape of a brown oil, which solidifies on cooling, and is best purified by steam distillation in presence of SO_2 .

p-Iodo-anisol, $C_6H_4(OCH_3)I$ [1:4], is prepared in the same way as the ortho compound. It is a solid body, and crystallises in white leaflets. It melts at 51 — $52^{\circ}C$, and boils at $237^{\circ}C$. (725 mm.).—H. T. P.

Dimethylaniline, Derivatives of. [Direct Cotton Dye.] A. Schuster and J. Pinnow. *Ber.* 1896, 1053.

DIMETHYLANILINE dissolved in dilute sulphuric acid and treated with dilute nitric acid, forms α -dinitrodimethylaniline. By reduction, this forms α -diamidodimethylaniline, which is partially decomposed by distilling at the ordinary pressure, but distils at $178^{\circ}C$. under 22 mm. pressure.

Methylethylacetamidophenylene-amidine.—The diamido compound is added to 4—5 times its weight of boiling acetic anhydride, well shaken, and kept boiling for four hours. Then half is distilled off. The remainder is treated with water, boiled down, and then precipitated with

soda. The precipitate, after being washed and dried, is dissolved in luke-warm methyl alcohol (2 c.c. for 1 gm. of substance), reprecipitated with five or six times its volume of ether, and lastly crystallised from water. The substance which separates out from the methyl alcohol and ether solution after standing a few days, is, according to Warster and Seldtner (*Ber.* 12, 1806), the *mono*-acetyl derivative, and should therefore contain a free amido group capable of being diazotised.

No diazo compound could be formed, and the substance was shown to be diacetyldiamidodimethylaniline.

By boiling with hydrochloric acid, methylethylacetamidophenylene-amidine loses its acetyl group; the base separates out with potash, is extracted with chloroform, and, after evaporation of the latter, is re-crystallised from water. The diazo compound of this base is very stable; the *azo*-colour made from methylethylacetamidodiphenylene-amidine and β -naphthylamine, viz.:—

dyes unmordanted cotton direct, like the *azo* colours prepared by Lellmann and Heiler (*Ber.* 26, 2759) from amido-benzylphenylenediamine. These authors showed that the imido group may be substituted for sulphur in the group—

characteristic for primuline *azo* colours. The methylethylacetamidophenylene-amidine contains a group which is not exactly like, but to some extent resembles, the group in Lellmann and Heiler's compound.

Methylethylacetamidophenylene-amidine hydrochloride, $C_{11}H_{11}N_3.2HCl$, crystallises from methyl alcohol in needles melting at 260° .—H. M.

Naphthalene Derivatives, Isomeric. III. P. Friedländer and H. Rüdrt. *Ber.* 29, 1609—1613.

THE authors describe the preparation of naphthoresorcinol according to the method already described (this Journal, 1896, 110), and they have also obtained naphthofluorescein. They describe some further reactions of 1,3-dihydroxynaphthalene, which melts at $124^{\circ}C$, and gives an acetyl derivative melting at $56^{\circ}C$. Nitrosodimethylaniline acts on the compound in acetic acid solution, forming a reddish-violet colouring matter which turns green with hydrochloric acid, thus differing from the 2,3-derivative, which forms an iodo-blue oxazine, which is unaltered by hydrochloric acid. The *azo* compounds of 1,3-dihydroxynaphthalene differ from their isomerides both as regards shade and behaviour on reduction. They are all coloured yellow, and on reduction yield presumably 2,1,3-amidodihydroxynaphthalene, which in presence of alkali oxidises very rapidly in the air, turning dark green and then dirty brown when spotted on filter paper. The sulphonic acids of the naphthoresorcinol show a similar reaction. When 1,3-dihydroxynaphthalene is heated for several hours to about $190^{\circ}C$. with 60 per cent. caustic soda, it takes up water, yielding acetic acid and *o*-toluic acid melting at $105^{\circ}C$. On heating with ammonia to $140^{\circ}C$, the β -hydroxyl is first substituted, 3,1-amidonaphthol being obtained together with some 1,3-naphthylendiamine. The former gives a sparingly soluble hydrochloride, and oxidises very easily in presence of alkalis. When 1,3-dihydroxynaphthalene is boiled with an excess of aniline, there remains, after distilling off the excess, a white precipitate of phenylamidonaphthol, which behaves in an alkaline solution in a characteristic manner on exposure to air. The solution, which rapidly turns brownish, deposits small violet-red crystals consisting of naphthoquinone-anil. The paper concludes with a description of two naphthoresorcinol sulphonic acids.

—T. A. L.

Thiodiphenylamine [Chloro Derivatives]. O. Unger and K. A. Hofmann. *Ber.* 29, 1362—1368.

When thiodiphenylamine is heated with aniline and aniline hydrochloride, it yields a blue colouring matter (*Ber.* 27,

3324). The yield can be improved by shortening the duration of the melt and adding certain oxidising agents, or else by using instead of thioldiphenylamine the violet-black product obtained by the action of nitrous acid gas on the ethereal solution of thioldiphenylamine. In the present communication the authors describe the action of hydrochloric acid on this substance, forming mono-, di-, and tetrachlorothioldiphenylamine. The last-named product is best obtained by passing nitrous acid gas (from nitric acid sp. gr. 1.3 and arsenious acid) through a solution of thioldiphenylamine in ether, warming the precipitate with alcoholic hydrochloric acid, and extracting with alcohol, when the tetrachloro derivative remains undissolved. The direct action of nitric acid on warming gives rise to the formation of a nitro compound with elimination of chlorine, but nitration in acetic acid does not take place, for a sulfoxide is formed. Hence the chlorine atoms appear to occupy both the *o*- and *p*-positions. Dichlorothioldiphenylamine is contained in the alcoholic extract mentioned above, and can be purified by repeated crystallisation from benzene and alcohol. It crystallises from alcohol in small shining plates, which gradually turn green on exposure to air. On nitration, it forms dinitrodichlorodiphenylamine sulfoxide, which crystallises from nitric acid in yellow needles. This product, on reduction, forms leuco-isothionine. An isomeric dichloro derivative which appears to have both chlorines in the *p*-position, since on nitration and reduction it does not give any colouring matter, is obtained together with tetrachlorothioldiphenylamine, by the direct chlorination of thioldiphenylamine. The product of the action of nitrous acid gas on thioldiphenylamine has a quinonoid structure, and this is borne out by the fact that on heating with aniline and aniline hydrochloride, blue colouring matters are obtained which have been identified as phenylated and anilido-phenylated thionines.—T. A. L.

Products obtained in the Chlorination of Benzaldehyde and their Derivatives. R. Gnehm and E. Bänziger. Ber. 29, 875—878.

By the action of iodine and antimony pentachloride on benzaldehyde, a number of compounds are produced, the principal product, however, being 2,5-dichlorobenzaldehyde. The authors have separated the various products, and identified them, and have investigated the colouring matters derived from 2,5-dichlorobenzaldehyde, or from the above mixture. For instance: *New Solid Green 3B* is a mixture of the nitric and hydrochloric acid salts of tetramethyldiamidodichlorotriphenylcarbinol. *New Solid Green 2B* consists of the hydrochlorides of the same carbinol, together with tetramethyldiamidochlorotriphenyl carbinol, and also contains sodium and zinc sulphate. *Glacier Blue*, obtained by condensing methyl-*o*-toluidine with 2,5-dichlorobenzaldehyde, is the hydrochloride of dimethyldiamido-di-*o*-tolyl-dichlorophenyl carbinol.—T. A. L.

Triphenylmethane Colouring Matters. Constitution of. Hugo Weil. Ber. 29, [10], 1541—1542.

G. VON GEORGEVICH has stated (this Journal, 1895, 150) that when a cold dilute solution of pure rosaniline hydrochloride is treated with a very slight excess of cold dilute caustic soda, a precipitate of a coloured base is obtained. This was considered by him to be the true base of the rosaniline colouring matters.

The author has been unable to confirm these results, and finds that under the above conditions no precipitate is formed until the solution is "salted out," when the unchanged hydrochloride is recovered. More concentrated solutions yield, it is true, a coloured precipitate, but that always contains chlorine.

On treating a rosaniline hydrochloride solution with moist silver oxide, gradual precipitation of the ordinary colourless base takes place, the solution retaining its colour as long as any chlorine is present.

The colouring matters of the rosaniline series behave as true quaternary ammonium salts.—H. I.

Fuchsines, Properties of and Oxidation by Lead Peroxide. M. Prud'homme. Bull. Soc. Chim. 1896, 780—783.

In pointing out that Patent blue is not an ether (Bull. Soc. Chim. 1895, 907), the author is at variance with Rosenstiehl,

who considers that this constitution explains its behaviour with caustic alkalis. The former states, moreover, that in the reaction he has described, more particularly the transformation of blue decolorised by soda into tetra-ethylbenzidine, he never stated that this was characteristic of fuchsine colouring matters fast to alkalis. In fact, blue decolorised by soda is easily transformed into tetra-ethylbenzidine on oxidation with lead peroxide and acetic acid, whilst Patent blue under the same conditions does not give an alkylated benzidine. According to Rosenstiehl, the precipitate obtained by the action of ammonia on alkylated fuchsine contains a mixture of the carbinol with the fuchsine, and is coloured. As a matter of fact, the addition of ammonia to solutions of Fuchsine, Hexamethyl violet, and Malachite green, gives colourless solutions after a short time, and the bases also are colourless. On the other hand, *m*-hydroxylated Malachite green gives a dark green base with ammonia, and the author is of opinion that this colour is a property of the base—

In oxidising dimethylaniline or tetramethyldiamidodiphenyl carbinol, dissolved in the theoretical amount of hydrochloric acid, with lead peroxide and acetic acid, the liquid turns yellowish-orange and then green on adding sodium acetate, and dyes silk a fugitive grass-green. On heating the liquor, it becomes decolorised and alkylated benzidine is precipitated. The oxidation of the fuchsines proceeds in an analogous manner, except that of course a much larger quantity of lead peroxide must be employed. The following colouring matters have been investigated:—

Malachite green.—This is converted into bluish-green colouring matters dyeing silk blue, maximum blueness being obtained with four molecules of lead peroxide. With eight molecules, the green entirely disappears and the filtered liquid is yellowish-orange, which becomes green on adding sodium acetate, and dyes silk grass-green. The ultimate product is alkylated benzidine. *Helectia green*, which is Malachite green sulphonated in the para-position, behaves in an exactly similar manner. *m-Hydroxylated Malachite green* dyes silk a very yellowish-green, the shade becoming darker after oxidation with 4 molecules of lead peroxide, and the transformation into alkylated benzidine being complete with eight molecules. *Patent blue* is the disulphonic acid of the foregoing, and gives a dark blue with 4 molecules of lead peroxide, whilst with 6 the transformation is complete. The resultant compound is not a blue colouring matter, nor is it an alkylated benzidine. In the case of Patent blue decolorised with soda, the addition of an equimolecular proportion of lead peroxide gives directly alkylated benzidine. *Hexamethyl-p-fuchsine* gives a violet with 4 molecules of lead peroxide, the complete transformation requiring eight. *Fuchsine* gives with 3 molecules of the oxidiser a colouring matter dyeing silk garnet, whilst with 6 molecules benzidine is formed. Hence, of the substances studied, only Patent blue and its derivative decolorised by soda behave in a special manner. Under no circumstances does the former yield an alkylated benzidine, whilst the latter gives it with a single molecule of the oxidiser directly, without the formation of an intermediate compound. The fuchsines are transformed into new colouring matters on oxidation by the removal of hydrogen from the benzene nucleus adjacent to the methane carbon. This requires generally about 4 molecules of lead peroxide, and the further oxidation, which usually requires about twice this amount, probably acts in splitting up that benzene nucleus which took part in the first phase of the reaction.—T. A. L.

Fuchsines and Amido-carbinols, Certain Reactions of. A. Rosenstiehl. Bull. Soc. Chim. 1896, 15, 327—330.

AN extended criticism of Prud'homme's views as to the constitution of Patent blue (this Journal, 1895, 27; 1896, 267, 268).

The author, in collaboration with Smis, has discovered that alkyl-benzidines are amongst the products of oxidation of the leuco bases of various colouring matters which contain

the group $C_6H_4NR_2$ (R being an alkyl group), such as Malachite green and the Acid greens, the latter of which are sensitive to alkalis. They are contained in the deposits of (lead sulphate or chloride, formed from the lead dioxide employed for oxidising, and their formation partially accounts for the loss of colouring matter which is experienced in the manufacture of the colouring matters in question.

With respect to the green precipitate (this Journal, 1896, 268) obtained by the action of ammonia on the unsulphonated Patent blue, the author remarks that (1) ammonia is incapable of completely saponifying the alkyl-rosaniline compounds which exhibit even a feeble resistance to alkalis, the carbinols of such compounds being able to decompose ammoniacal salts, even in the presence of ammonia, so that the precipitates, formed by means of ammonia, contain the undecomposed colouring matters along with the colour-bases; (2) the carbinols, even when pure (*i.e.*, colourless), give with pure alcohol coloured solutions, at all events in the absence of an excess of alkali; (3) the amido-carbinols known (*e.g.*, the colour-bases of Malachite green, Crystal violet, &c.), derived from rosanilines, whether fast to alkalis or not, dye wool and silk, and cotton mordanted with tannic acid; the only logical conclusion, however, which can be drawn from this is that wool and silk, like tannic acid, furnish the acid requisite for the formation of coloured salts.

The author does not maintain that coloured amido-carbinols cannot exist. His position is that no such compounds have yet been discovered.—E. B.

Fluorindines, Constitution of the. III. F. Kehrman and H. Bürgin. Ber. 29, 1246—1254.

THE authors have further investigated Fischer and Hepp's phenylfluorindine formula—

according to which mono- and dialkylated or acetyl derivatives should be obtainable, the substitution taking place at the nitrogens. Employing the method already given (Ger. Pat. 78,601; Ber. 28, 1543; this Journal, 1895, 859), several substituted fluorindines have been obtained. It appears to be a general characteristic of the mono-alkylated fluorindines, owing to their tolerably strong basic nature, that on boiling with benzoic ethyl ether they are more or less rapidly converted into benzoyl derivatives, whilst the diphenyl fluorindines can be crystallised unchanged from the same medium. *Phenylphenylfluorindine* has been obtained either by condensing 2-hydroxyphenylphenazone (Annalen, 290, 301) and *o*-phenylenediamine hydrochloride, or else by condensing the latter product with the hydrochloride of the oxidation product of *o*-amidodiphenylamine; and Fischer and Hepp's statement (Ber. 28, 295; this Journal, 1895, 565) that the latter process gives diphenylfluorindine, is incorrect. The product is identical with that obtained by Fischer and Hepp from aposafranine and *o*-phenylenediamine (Ber. 29, 367; See next abstract but one), and gives a benzoyl derivative when boiled with benzoic ether. Its hydrochloride is sparingly soluble in alcohol. *Diphenylfluorindine* is obtained by condensing *o*-amidodiphenylamine with the hydrochloride of its oxidation product by means of benzoic acid. The same substance is produced by oxidising azophenine with yellow mercuric oxide. It has the formula given at the commencement of the paper, the two imide hydrogens being replaced by phenyl groups. *Methylphenylfluorindine* is formed by condensing the hydrochloride of the oxidation product of methyl-*o*-phenylenediamine with *o*-phenylenediamine hydrochloride in presence of benzoic acid. The base has the formula—

Ortho-amidodiphenylamine, Oxidation Products of.
O. Fischer and A. Dischinger. Ber. 29, 1602—1608.

In criticising Kehrman's proof (Ber. 29, 1249; see Kehrman and Bürgin, previous abstract) of the constitution of

the oxidation product of *o*-amidodiphenylamine, the authors point out that three years ago Heiler and Fischer (Ber. 26, 378; this Journal, 1893, 751) had already recognised the product as anilido-aposafranine. The reason for the higher melting point found, was the presence of another substance very similar to anilido-aposafranine, which Kehrman and Messinger had also overlooked. It has not been possible to obtain an oxidation product in which a free amido group could be detected, which should be the case if Kehrman's formula were correct. Fischer and Heiler's results as regards the decomposition of the oxidation product are confirmed, 11-anilidobenzene indone and 11-*o*-oxybenzene indone being obtained, the former being insoluble and the latter soluble in dilute caustic soda. Hence the chief oxidation product of *o*-amidodiphenylamine by means of ferric chloride is identical with anilido-aposafranine. As regards the second substance formed, it melts at 259° C., and is characterised by the bronzy-yellow colour of its hydrochloride. The base has the formula $C_{26}H_{22}N_2$, and on decomposition with dilute sulphuric acid at 170° C. gives two products, one insoluble and the other soluble in alkalis, and identical with oxyaposafranone. Furthermore, on heating with *o*-phenylenediamine and its hydrochloride to 210° C., a fluorindine is obtained. At the conclusion of the paper, Fischer and Hepp, replying to Kehrman's last paper, point out that the conclusion of the latter that the formation of phenylfluorindine from *o*-phenylenediamine and the oxidation product of *o*-amidodiphenylamine, is a proof that the latter has the constitution given, must be incorrect.

Finally, the authors do not confirm Kehrman and Bürgin's statement that phenylfluorindine cannot be recrystallised unchanged from benzoic ether.—T. A. L.

Relation of the Indulines to the Safranines. F. Kehrman, Annalen, 290, 247—306.

THE author concludes from the experimental evidence brought forward in the paper that the question as to the difference between the indulines and safranines reduces itself to the position and nature of the substituting amido groups. Both series of compounds belong to one large class—the azonium bases and their amido or hydroxy substitution products. The non-substituted azonium bases only exist in the hydrate form, and this also is the case with those substituted azonium bases, which, owing to the position of the substituting groups, are incapable of undergoing the *p*-quinoid anhydride formation (induline or indone formation), whereas those substituted azonium bases which contain amido or hydroxy groups in a suitable position can sometimes exist as hydrates, but lose water very easily. This is the case with rosinduline, aposafranine, and phenosafranine. The indulines and indones thus formed do not give different salts from the corresponding azonium hydrates. The salts of both forms of the bases are identical, since simultaneously with the formation of the salt, molecular transformation into the *o*-quinonoid azonium form takes place. In a preliminary notice (Ber. 27, 3349), the formation of rosinduline chloride by means of the azonium reaction and the behaviour of acetyl rosinduline chloride showed definitely the relationship between the safranines and indulines, and further experimental evidence is brought forward in the present paper in support of this view.

In conclusion, a number of new condensation products are described, obtained by the action of benzyl-*o*-phenylenediamine on 4.1.2-acetamidonaphthoquinone and on 2.1.4-hydroxynaphthoquinone. The former compound, when condensed, gives benzyl chloride, acetamidonaphthophenazine and acetylbenzyl rosinduline chloride. From 2.1.4-hydroxynaphthoquinone, benzylrosindone, hydroxynaphthophenazine, and benzyl chloride or benzyl alcohol are obtained. Similar condensation products resulting in the formation of phenazone derivatives are obtained from alkylated or phenylated *o*-phenylenediamines and dihydroxyquinone, dihydroxytolquinone, and chlorodihydroxyquinone.—T. A. L.

Indulines and Safranines. O. Fischer and E. Hepp. Ber. 29, 361—371.

THE mauves, indazines, rosindulines, Naphthyl red and blue, and Magdala red all belong to the class of the

p-quinones, and this is also true of the safranines—a fact which has been recently demonstrated (this Journal, 1896, 192). All these compounds react with bases to form indulines, the formula of the simplest induline being—

in which R can be either methyl, ethyl, or phenyl, &c. The safranines are distinguished from the indulines by their characteristic behaviour in sulphuric acid. The simple safranines, aposafranine, phenosafranine, mauveine, indazine, and rosinduline dissolve in concentrated sulphuric acid with a green colour, whilst the anilides dissolve to violet or blue solutions. Recognising the relationship between the safranines and indulines, it is no longer necessary to insist on the old ammonium formula for the safranine salts, and Kehlmann's view (Ber. 28, 1710; this Journal, 1895, 858) that the salts of the induline bases and indones (rosinduline, &c.) are derived from an *o*-quinonoid azonium formula whilst the oxygen free induline bases and the indones are only *p*-quinonoid anhydrides of amido or of hydroxy-azonium bases, is untenable. It is more probable that the strong basicity of many of these colour bases is due to the imido group, and not to the azine nitrogen. Hence aposafranine hydrochloride has probably the formula—

By the action of aniline on aposafranine salts, two compounds are obtained, the one being anilido-aposafranine, $\text{C}_{22}\text{H}_{18}\text{N}_4$, the other phenylanilido aposafranine, $\text{C}_{30}\text{H}_{24}\text{N}_4$ —

This constitution is proved by splitting off successively the two phenyl groups, leaving finally hydroxyaposafuranone, which was characterised by conversion into its methyl ether (red needles or prisms melting at 248°C). In a similar manner two products are obtained by the action of *p*-toluidine on aposafranine. With *p*-phenylenediamine, *p*-amido-anilido-aposafuranine is obtained, which crystallises from benzene in bluish-green prisms, melting at 227°C . On heating with dilute sulphuric acid to 170°C , *p*-phenylenediamine and hydroxyaposafuranone are produced. By reacting with *o*-phenylene diamine on aposafranine chloride, phenylfluorindine—

is produced, which bears out the authors' formula for the fluorindines. As already observed, anilidophenylaposafuranine (formerly known as phenylinduline) is obtained from aposafranine or from anilido-aposafuranine by the action of aniline. It can further be obtained by removing the amido group from amidophenyl induline, which is an important induline of the amido-azobenzene melt. This compound has the constitution—

and it can be converted by heating with dilute sulphuric acid first into amidohydroxyaposafuranone, and subsequently into dihydroxyaposafuranone. Decomposition with an alkali yields safranin and anilidosafuranol. Its relationship to phenosafranine, mauveine, and phenylmauveine is shown by the fact that the same induline is obtained from it as

from these compounds, when heated with aniline. This product is formed in the induline melt, and is the greenish-blue induline remaining behind when the induline melt is extracted with alcohol. It forms a characteristic acetate, which crystallises from acetic acid in flat bronzy prisms. It has most probably the formula $\text{C}_{20}\text{H}_{16}\text{N}_6$, since in its production from phenylmauveine an intermediate product can be isolated, which melts at 215°C , and has the formula $\text{C}_{20}\text{H}_{16}\text{N}_6$.—T. A. L.

Safranines, Constitution of. R. Nietzki. Ber. 29, 1442—1446.

The author points out that in almost all the previous work (see preceding abstract) on the safranines the symmetrical formula has been adopted, although their constitution, according to the methods of preparation, could be equally well expressed by the unsymmetrical formula. Hitherto the isomerism of aposafranine and the simplest induline has been taken as evidence of the correctness of the latter formula, but since Kehlmann has shown that the simplest induline does not exist, there is no longer a necessity for expressing a distinction. Experimental evidence is now brought forward, at any rate for mauveine, in support of the symmetrical formula, and the author adopts it also for all the safranine colouring matters. The joint oxidation of *m*-amidodiphenylamine and *p*-amido-diphenylamine, or of diphenyl-*m*-phenylenediamine and *p*-phenylenediamine, could take place in either case in two ways. Since, however, the same colouring matter is obtained by either method, the product must be formed according to the following scheme—

and hence mauveine is expressed by a symmetrical formula. This, then, follows for all the allied colouring matters. The substance, in view of its strongly basic character, has an azonium rather than a quinone-imide formula, and this view obtains especial support in the strong basicity of diacetyl-safranine. In a similar manner the reddish-violet base acetylposafuranine, gives yellow salts which are not decomposed by dilute alkaline carbonates. Fischer and Hepp's statement that aposafranine cannot be diazotised is not confirmed by the author. At any rate, if just sufficient acid be added to an aqueous aposafranine solution until it just begins to turn green, on adding sodium nitrite it turns yellow. No colouring matter is formed with alkaline β -naphthol solution, but the addition of cuprous chloride causes a violent evolution of nitrogen, and the colour of the solution changes. With respect to Kehlmann's view that the anhydrous bases are expressed by quinone-imide formulae, it would appear more probable (since such a transformation would certainly be evidenced by a change of colour, and the safranines are distinguished from the eorhodines and true indulines by their stability to alkalis) that an inner anhydride formation takes place between the ammonium hydroxide and the amido or hydroxyl group. That the rosindulines and rosindones have an analogous constitution is sufficiently evident from their properties.—T. A. L.

Phenazine Colouring Matters, Nomenclature of. IV. G. P. Jaubert. Ber. 29, 414—418.

The author suggests a scheme for the nomenclature of the various phenazine derivatives (this Journal, 1895, 858), to which belong the eorhodines, safranines, indulines, and mauveines, &c. It is proposed to number the parent substance, phenazine, as follows:—

It will be seen subsequently that in the induline colouring matters the α -nitrogen plays the same part as the methane carbon in triphenylmethane derivatives. The

phenazine derivatives can be divided into two classes—the eorhodines and the indulines. The former have an o-quinonoid structure—

whilst the indulines are *p*-quinonoid derivatives—

As already mentioned (Ber. 28, 1585; this Journal, 1895, 858), the simplest representatives of the eorhodines and indulines are isomeric. The above formulae will explain the stronger basicity of the eorhodines and their diazotizability in contrast to the indulines, which are weaker bases and non-diazotizable. The simplest eorhodine is 3-amidophenazine, which yields 3-hydroxyphenazine or eorhodol, when the amido group is replaced by hydroxyl. The introduction of an amido group para to the α -nitrogen yields amido-eorhodine or Phenylene red (3,3'-diamidophenazine). The dimethyl derivative of this substance is Neutral violet. If one amido group be replaced by hydroxyl, amido-eorhodol is obtained, whilst the replacement of both amido groups yields hydroxyeorhodol. With regard to the *p*-quinonoid derivatives, the simplest induline—

has not yet been prepared. Replacement of the amido group by oxygen yields indulone (Fischer and Hepp, indone). In order to designate substitution in the azine ring, the author adopts Witt's suggestion, making use of the prefixes, metho-, etho-, pheno-, α - and β -naphtho-, &c., whilst the usual prefixes methyl, ethyl, phenyl, &c., are employed to denote substitution in the amido or imido groups. Hence aposafranine is pheno-induline and safranine is pheno-indulone. The introduction of an amido group into the simplest induline para to the α -nitrogen gives the simplest safranine, whilst if the imido group be replaced by oxygen there results amido-indulone, from which hydroxyindulone or safranil can be obtained by substituting the hydroxyl for the amido group. Several compounds belonging to this class have already been described (Comptes rend. 121, 947; this Journal, 1896, 108). In conclusion, the author points out some analogies between Malachite green and *p*-rosaniline, induline, and safranine. The introduction of an amido group into the benzene ring of diamidotriphenylmethane (unmethylated Malachite green) para to the methane carbon, yields *p*-rosaniline. Substitution in any other position ortho or meta gives colouring matters which have little in common with *p*-rosaniline. This is also true as regards the formation of safranine from induline. A safranine is only formed when the amido group enters the molecule para to the α -nitrogen. The function of the β -nitrogen appears to be that of strengthening the molecule, like the sulphur in Methylene blue or the oxygen in Nile blue, preventing its decomposition by acids like the indamines.—T. A. L.

Dibromo-Gallic Acid and its Derivatives, Action of Nitrosodimethylaniline on. [Gallocyanine.] A. Biétrex. Bull. Soc. Chim. 1896, 15, 104—408.

A monobromo-derivative of Gallo-cyanine is obtained by heating dibromo-gallic acid (1 mol.) with nitrosodimethylaniline hydrochloride (1 mol.) in methyl alcoholic solution.

It differs from Gallocyanine in its reactions mainly in not being affected by the addition of acid to its aqueous solution, Gallocyanine changing in colour from blue to violet-red when its aqueous solution is so treated.

The monobromo-derivatives of Prune and Gallanilic violet are similarly obtained from nitrosodimethylaniline and the methyl ether of dibromo-gallic acid and dibromogallanilide, respectively.—E. B.

Casein, Colour-Lakes prepared from. C. Dreher. Färb. Zeit. 1896, 7, 164—165.

COLOUR-lakes, which possess the advantages of being very pure in shade, fast to water, relatively inexpensive, and innocuous, are produced by precipitating casein, from an ammoniacal solution, in the presence of the (basic or acidic) colouring matter of the shade desired, by means of stannic chloride, basic stannic acetate, aluminium acetate, or aluminium chloride.

An Auramine (yellow) lake is, for instance, prepared from the following solutions:—

Casein Solution.—10 parts of powdered casein are made into a paste with 20 parts of water, and then 80 parts of water and 1—2 parts of ammonia solution are added. The whole is heated at about 40° for two hours. The liquid is then strained through fine cloth to remove undissolved matters.

Dyestuff Solution.—5 parts of Auramine are dissolved in 1,000 of water at 60°.

Stannic Chloride Solution.—10 parts of the crystallised salt in 1,000 of water.

The lake is obtained by mixing 30 parts of kaolin with 20 of warm water and 80 of casein solution, adding 100 of the dyestuff solution and, lastly, while stirring, the stannic chloride solution (about 2 parts are required) until the colouring matter is completely precipitated. The precipitate is collected, pressed, and dried at 60°.—E. B.

Magenta and Acid Magenta, Distinction between; Schiff's Reaction. P. Cazeneuve. J. Pharm. Chim. 1896, 3, [11], 595.

See under XXIII., page 560.

PATENTS.

Colouring Matters [Cotton Bluish-Blacks], The Manufacture or Production of. H. E. Newton, London. From "The Farbenfabriken vormals F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 13,626, July 16, 1895.

ACCORDING to Eng. Pat. 7337 of 1892 (this Journal, 1893, 350), of which this is an extension, colouring matters are obtained by combining diazotised amido-azo compounds with phenyl- or tolylnaphthylamine sulphonic acids. In the present specification these latter compounds are replaced by alkylated naphthylamine sulphonic acids, such as methyl-, ethyl-, or benzyl- α - or β naphthylamine sulphonic acids, or by alkylated naphthylamine disulphonic acids. The alkylated naphthylamine sulphonic acids are produced in the usual manner by the action of an alkyl haloid on the particular naphthylamine sulphonic acid in the form of its sodium salt, under pressure, and with or without the presence of an alkali. Thus an aqueous solution of one molecular proportion of 1.1'-naphthylamine sodium sulphate is heated with one molecular proportion of ethyl bromide in an autoclave to 90°—100° C. with constant agitation until the pressure disappears. The melt is then allowed to cool, and the ethylated naphthylamine sulphonic acid is separated in the usual manner. The following example illustrates the formation of a colouring matter:—The diazo solution from 17.3 kilos. of *m*-sulphanilic acid, 7 kilos. of sodium nitrite, and sufficient hydrochloric acid, is run into 800 litres of water containing 18 kilos. of α -naphthylamine hydrochloride. The formation of the amido-azo compound is assisted by the addition of sodium acetate and by slightly warming the liquid. When cold, 30 kilos. of hydrochloric acid (30° B.) and 7 kilos. of sodium nitrite are added. The formation of the diazo-azo compound is complete in about 12 hours, when it is filtered off and stirred into a solution of 25 kilos. of 1.1'-ethylnaphthylamine sulphonic acid, together with 5.3 kilos. of sodium carbonate. The formation of the dyestuff is completed by adding 7 kilos. of sodium acetate, and by gently warming the mixture. The colouring matter is separated in the usual manner, and the acid has the following formula:—

It dyes unmordanted cotton fast bluish-black shades. Other variations are described.—T. A. L.

Meta-nitraniline-sulpho Acid and its Analogues. Manufacture of. O. Imray, London. From "The Farbwerke vormals Meister, Lucius, and Brüning," Hoechst a. M., Germany. Eng. Pat. 14,382, July 29, 1895.

By the action of neutral sulphites on *m*-dinitro compounds of the benzene series, a reaction takes place according to the following equation:—

A solution of 5 kilos. of neutral sodium sulphite in 20–25 litres of water is heated to boiling, and 1.68 kilos. of *m*-dinitro benzene are added in small quantities with constant agitation. When the dinitrobenzol melts, a vigorous reaction ensues, and the mixture forms a clear yellowish-brown solution, from which small brownish-black needles of the new nitro-amido sulphonic acid may be separated by the addition of 2.5–3 kilos. of crude hydrochloric acid. The new acid, when pure, forms almost colourless needles, very sparingly soluble in cold water and fusible without decomposition. It dissolves easily in alkaline carbonates and in sodium acetate, and gives with nitrous acid a sparingly soluble diazo compound. The acid, from the above properties, appears to be different from the *m*-nitraniline sulphonic acid of Post and Hartung (Annalen, 205, 102). In a similar manner to the above, a corresponding acid may be obtained from dinitrotoluene [$CH_3 : (NO_2)_2 = 1 : 2 : 1$], although the reaction does not take place so smoothly. The resulting nitrotoluidine sulphonic acid is somewhat more readily soluble in water than the corresponding *m*-nitraniline derivative.—T. A. L.

V.—TEXTILES: COTTON, WOOL, SILK, Etc.

Sansevieria Zeylanica Fibre. Report on. Imp. Instit. Journal, Scient. Investig. Dept., July 1896, 264.

The fibre of this plant, which belongs to the natural order Liliaceæ, is of a beautiful light colour and fine gloss. The staple is about 4 ft. in length, of smooth well-formed threads.

The sample was obtained from Angoorie, in Assam, where Dr. Watt observed that it was being grown upon waste land by a tea-planter. Dr. Watt states that the plant can be grown without cultivation; if fragments of the leaves are scattered over the soil, each fragment takes root rapidly, and a good crop is yielded in a very short time.

Chemical examination shows this fibre to be of high quality. C. F. Cross examined a sample of "Sansevieria," which was included in the collection at the Indian and Colonial Exhibition, and also tested its paper-making qualities; the chemical results obtained by him showed that the specimen he examined was inferior in quality to the present sample. (Report on Indian Fibres, 1886.)

The following are the results furnished by the two samples:—

Sansevieria Zeylanica,	Assam.	From Colonial* and Indian Exhibition.
	Per Cent.	Per Cent.
Moisture	3.4	2.7
Ash	0.7	..
Loss by A. hydrolysis	11.8	12.0
" B.	14.9	16.5
" mercerising	11.6	..
" acid purification	1.4	2.5
Gain by nitration	33.5	6.0
Cellulose	75.6	64.6
Length of ultimate fibre in mm. ...	1.5–3.5	1.5–2.5

* Report on Indian Fibres.

With the exception of the results of chemical examination obtained in the Scientific Department of the Imperial Institute, there are very few available for purposes of general comparison of monocotyledonous fibres. Many of the fibres dealt with in these reports were obtained, it is true, from plants which were not indigenous to the locality

they were grown in. Special care, however, had been taken in the cultivation and treatment, so that the fibre which they furnished was probably little inferior to the same kind of fibre derived from the wild plants grown in their natural habitat. Accepting the results which they furnished as suitable for purposes of general comparison, it appears that the "cellulose" numbers furnished by fibres of monocotyledonous origin range from about 61 to 77, the average number being about 70. The "nitration" numbers range from 9 to 34, with an average of about 20.

Sansevieria, which furnishes the numbers 75 and 33 respectively, therefore ranks high among these fibres. Again, the A. and B. "hydrolysis" numbers, and especially the difference between them, are of special significance. The Victorian monocotyledonous fibres may, indeed, be classified from this point of view. Thus, the approximate hydrolysis numbers and the differences are, respectively, for the Cordylines, 15, 19, and 4; for the Agaves, 16, 21, and 5; for the Kniphopas, 17½, 23, and 6.

Sansevieria gives the numbers 12, 15, and 3. These would indicate that it should possess special powers of resistance to weathering and the accompanying hydrolytic effects. The general results of chemical examination of this fibre may be considered as very satisfactory. A comparative statement of the results furnished by the monocotyledonous fibres, showing the relation of *Sansevieria* thereto, is appended:—

	A. Hydro-lysis.	B. Hydro-lysis.	Difference.	Cellulose.	Nitration.
	No.	No.		No.	No.
Cordylines	15	19	4	68½	18
Agaves	16	21	5	75½	19
Kniphopas	17½	23	6	71	29
General range	10–18	20–30	10	61–77	9–34
Sansevieria Zeylanica	12	15	3	75½	33

The reports of experts on this sample of *Sansevieria* were favourable, although it exhibited some trifling defects, due, probably, to the degree of maturity of the plant from which it was prepared.

Silk, Weighting Materials in: The Quantitative Estimation of. H. Silbermann. Chem. Zeit. 20, 472.

See under XXIII., page 563.

PATENTS.

Wools, Woollen Rugs, or Tissues [Carbonisation] intended to be Carbonised or Bleached, A Process for the Acidulation of. G. Philips, Stolberg, Germany. Eng. Pat. 12,857, July 3, 1895.

In order to effect a complete and rapid saturation of the matters which are to be destroyed, the woollen materials are treated with a dilute solution of the acid to be applied, in a vessel from which the air is exhausted.—E. B.

Treatment of Vegetable Fibres [Preparing for Spinning]. Improvements in the. C. Etros, New York, U.S.A. Eng. Pat. 7405, April 7, 1896.

VEGETABLE fibres in general, but, more particularly, those which are used in the manufacture of ropes and cordage, as hemp, linen, and jute, are improved in appearance and better adapted for spinning "or otherwise working," by impregnating them with a solution of sodium phosphate, "or of a caustic alkali," or of a mixture of some or all of the following substances:—Magnesium silicate (this may be replaced by kaolin, steatite, potassium or sodium silicate, or other substances), glucose, wheaten flour, paraffin wax (for which may be substituted stearin, bees-wax, mineral wax, or vegetable wax), "alkali soap," neutral soap, creasote, sodium phosphate, paraffin oil, tallow, and water. The solution or mixture may be applied in various ways, one of which is to spray it, heated at about "60° R." upon the fibres previously spread out and heated at about the same temperature.—E. B.

VI.—DYEING, CALICO PRINTING, PAPER-STAINING, AND BLEACHING.

Textile Fibres, Animal, Bleaching of, by Hydrogen Peroxide. G. Dommergue. *Rev. de Chim. Ind.* 1896, 7, 75, 73—74.

THE apparatus employed for bleaching tissues consists of two eubical tanks: one for the treatment with hydrogen dioxide, the other for rinsing. The first of these is provided with a cover, winches, and squeezing rollers. It is filled with hydrogen dioxide solution (12—14 vols.), diluted with 20 times its volume of water, and rendered slightly alkaline with either sodium or potassium hydroxide, or ammonia. The pieces, previously thoroughly scoured, are introduced into the bath, and worked therein for 6 to 10 hours, according to the degree of bleaching to be attained. They are then squeezed and withdrawn, and are afterwards washed, hydro-extracted, and dried.

"Market whites" are produced by faintly tinting the tissues thus bleached, with blue-violet dyestuffs, such as "Methyl violet, 350 N." or "Crystal violet."

Pelgrain's method for applying the hydrogen dioxide is more laborious and costly than the above. It consists in passing the tissues through an alkaline solution of hydrogen dioxide, contained in a mangle or dye-jigger, and receiving them on a wooden roller, leaving them on this for 12 hours, and then unrolling and washing.

Sodium silicate, which has been suggested as a suitable addition to the hydrogen dioxide bath, imparts a harsh feel to the tissues, and is not, therefore, to be recommended.

—E. B.

Lactic Acid as an Assistant in Mordanting Wool. E. Hoffmann. *Färber Zeit.* 7, 217—218. (See also this Journal, 1896, 196.)

FURTHER experiments have convinced the author of the superiority of lactic acid to other assistants when mordanting wool with chromium. The difference is most marked when pieces of wool mordanted respectively with "chrome" and tartar, chrome and oxalic acid, and chrome and lactic acid are all dyed in the same bath. Besides yielding fuller shades, lactic acid is cheaper than tartar. The present price in Germany is 60—65 M. per 100 kilos. The German commercial product contains 50 per cent. of lactic acid, that of American manufacture about 27 per cent. The shades produced are equal in fastness to those obtained with other assistants.—R. B. B.

Indigo Vat, The Stannous Chloride. F. Reisz. *Färber Zeit.* 7, 221—222.

THE author states that this vat, described by Dreher in *Färber Zeit.* 7, 115—117 (this Journal, 1896, 354), was referred to by Bancroft in 1826. Its great defect is that it undergoes rapid changes and can only be used for a short time, in this respect being inferior to the ferrous sulphate and zinc-powder vats. Owing to its strong alkalinity it is not suitable for wool dyeing. The ideal indigo vat is one in which some neutral organic substance yet to be discovered, acts as solvent for the indigo white.

—R. B. B.

Indigo Vat, The Stannous Chloride. A Reply to F. Reisz. (See preceding abstract.) *Färber Zeit.* 7, 222—224.

THE stannous chloride vat was not proposed as a substitute for the ferrous sulphate or zinc-powder vats, but for the hydrosulphite vat, over which it possesses the advantages of greater stability and less cost. It is especially suitable where dyeing is carried on in a closed vessel, e.g., in cop dyeing. The indigo vat of the future will more probably be one in which reduction is brought about by electrolytic action, unless, as is most likely, natural indigo is replaced within a few years by the artificially prepared product.—R. B. B.

Furs, The Use of "Ursol" in the Dyeing of. E. Gruene. *Färber Zeit.* 7, 197—200.

WITH the dyestuffs Ursol D, P, and C [the "Ursols" are para-amidophenol and *p*-phenylenediamine and their

derivatives] of the Berlin Actien Gesellschaft, it is possible to dye skins and furs in all shades, from the lightest brown to black. Two methods of application are recommended: either the wool is first mordanted with chrome and tartar, or it is dyed directly with Ursol. In both cases, towards the end of the dyeing operation an oxidising agent is added to the bath, and for this purpose hydrogen peroxide should be employed. Before dyeing the furs, &c., are cleansed from fatty matters by brushing with a solution containing lime. Dyeing is carried on at a temperature of 15—20° C. As an example, a dark brown may be thus dyed:—Mordant for three hours at 20° C. with 200 grms. of $K_2Cr_2O_7$ and 100 grms. of cream of tartar, dissolved in 100 litres of water. Dye with 200 grms. of Ursol D, dissolved in 100 litres of water. After dyeing at 20° C. for two hours, add 5 litres of H_2O_2 (3 per cent.), and continue steeping for four hours. To soften the leather after dyeing, it is brushed over with a solution of salt, and the fur is then revolved in a drum, in which it is closely packed with sawdust and sand.—R. B. B.

Wool- and Cotton-Dyestuffs, The "Overboiling" of.

M. Kitchelt. *Färber Zeit.* 7, 181—183 and 218—221.

ON long boiling with certain dyestuffs, the colour of the dyed wool is changed or destroyed. Complaints of this nature made with regard to sulphone-cyanine, that instead of blue, black or brown shades were obtained, led to the investigation of the causes of this defect. It was found only to exist in the case of wool containing a little alkali from the scouring process, and must be attributed to the reducing action of sodium sulphide. This is formed by a partial decomposition of the wool substance in alkaline solution, whereby sulphur is set free and enabled to combine with the alkali. This view is borne out by the fact that wool dyed with sulphone-cyanine and "overboiled" has the same colour as if "stoved" after dyeing. The remedy consists in making the bath faintly acid, and in adding a small percentage of $K_2Cr_2O_7$ towards the end of the operation to counteract reducing influences. The same change is noticed in goods which are steamed after printing or dyeing with sulphone-cyanine, and in this case $CuSO_4$ is employed as the oxidising agent.

Similar phenomena have been observed in cotton dyeing, but here the causes are different. Benzo fast grey is a dyestuff readily affected. In one case investigated, the defect was found to be due to the water used for dyeing, which was rich in organic impurities. The reducing action of these impurities can be prevented by boiling the water with $K_2Cr_2O_7 + H_2SO_4$ before dyeing. In other cases the reduction was due to the cotton having become mouldy, and here again preliminary treatment with $K_2Cr_2O_7$ and H_2SO_4 sufficed to prevent decomposition.—R. B. B.

PATENT.

Printing Inlaid Patterns upon Linoleum and like Fabrics, A Process for. J. E. and C. S. Belford, Leeds. Eng. Pat. 11,716, June 17, 1895.

THE object is to produce in an improved manner printed linoleum fabrics, with coloured designs penetrating to a greater or less extent the substance of the fabrics.

This is accomplished by printing (preferably by means of a block-printing machine) the pattern to be produced on the linoleum, upon a sheet of cartridge paper or calico, which has been previously sized to render it non-porous, and transferring by pressure to the porous linoleum, evenly spread upon a cloth backing.

The colours employed, consist either of pigments, ground to a stiff paste with boiled linseed oil, and mixed with a "volatile pigment vehicle" in the following proportions:—for example:—Pigment paste (5 parts), semi-solid, oxidised linseed oil (2), petroleum of sp. gr. 0.812 (3), turpentine (2), benzene (2), and resin ($\frac{1}{2}$), or of solutions of appropriate colouring matters, such as, for instance, rosaniline combined with linoleic acid in an oil-mixture similar to the above.

The object may also be attained by directly printing the colours upon the lightly-pressed surface of the porous linoleum composition.—E. B.

VII.—ACIDS, ALKALIS, AND SALTS.

Thirty-Second Annual Report on Alkali, &c. Works, by the Chief Inspector. May 12, 1896.

Mr. R. FORBES CARPENTER, who succeeded Mr. Fletcher in the office of Chief Inspector under the Alkali Works Act in June 1895, gives this year his first report, following the lines laid down by the first inspector, Dr. R. Angus Smith, and his successor. Of the present report, 97 pages are devoted to England, Ireland, and Wales, treated as seven districts, and the remaining nine pages are given to Scotland in a separate communication.

There has been a steady, though small, diminution in the average amount of acid gases escaping in alkali and in sulphuric acid works for the years 1893-95, the escape for all these years being greatly below the legal limit. The acid gas escaping by chimneys, including that produced from the sulphur contained in the coal used, is higher, but for this no standard is prescribed by the Act, though it is watched by the inspectors, especially in wet copper works and in sulphur recovery works.

The following table is given of the—

SALT DECOMPOSED IN THE LEBLANC AND AMMONIA-SODA PROCESSES (INCLUDING SCOTLAND).

	1895.	1894.	1893.
	Tons.	Tons.	Tons.
Leblanc process.....	408,173	434,298	467,562
Ammonia-soda	428,614	361,603	319,609
Total	836,787	795,901	817,171

Here the steady gain of the new process upon the old is clearly shown, and soon, it would appear, both processes are likely to have a new competitor in the electrical process, preparations for working which are being made by the Electro-Chemical Co., at St. Helens, using Holland and Richardson's process; by the Castner-Kellner Alkali Co.; and by Hargreaves and Bird's process for the production of alkali and chlorine, already worked out on the experimental scale at Farnworth. In obtaining alkali carbonate by this process, the voltage was so low as 3·2 to 3·5; but on working for alkali as caustic, the voltage rises, and Mr. Hargreaves claims "that from a given amount of electrical energy a greater aggregate market value is produced when working for carbonate of soda and injecting carbonic acid into the empty cathode compartments, than when working for caustic." The carbonic acid required, is obtainable from the exhaust of the gas-engine employed to run the dynamo.

The treatment of alkali waste does not appear to have made progress in the year past, and it is stated that "the problem of how to turn to account the 10 to 15 per cent. still lost as sulphur and escaping from the Chance-Claus process in gaseous forms and in the finely divided state of flowers of sulphur, is no step nearer solution," notwithstanding the ingenuity of many practical minds turned to the subject.

At Middlesbrough, a large plant is nearly completed for working Col. Sadler and Mr. Wilson's nitric acid chlorine process. In Scotland, the use of the oxidising action of nitric acid upon hydrochloric acid, has made no practical advance, and is not yet in operation in the manufacture of bleaching powder on a commercial scale.

Mr. Kessler's process for rectifying sulphuric acid at a temperature far below that attained by other apparatus, has been introduced in Scotland, and its illustrated description forms a feature in the report. Attention is directed to Dr. Valentiner's process of distilling weak nitric acid with sulphuric acid of sp. gr. 1·40 in a partial vacuum, at a temperature not above 100° C., monohydrate of 94 to 95 per cent. being obtained; but the process has not been actually introduced. Professor Hart's novel form of combined glass and earthenware condenser (this Journal, 1895, 967) has been introduced here, and should, it is stated, be of service in diminishing local escape from joints, as these are reduced in number, and the condenser is water-cooled instead of air-cooled.

In sulphate of ammonia works, the sulphuretted hydrogen evolved in the distillation of gas liquor is either, in large works having vitriol plant, converted first into sulphurous acid and then into sulphuric acid; or sulphur is obtained in the Claus kiln. In smaller works, the method of absorption in oxide of iron is generally used. The practice sometimes adopted of burning the gas and allowing the products to pollute the atmosphere, is strongly deprecated. The continuous distillation of gas-liquor is found to be not only economical, but to simplify the problem of dealing with the foul gases. It is stated that the use of valves of ordinary construction for shutting off access of foul gas to disused purifiers is attended with great risk, and description and drawings are given of a change water lute that has been advantageously used for many years in several sulphate works. The necessity, in designing sulphate of ammonia plant, to provide for the drawing off of the water condensed from the vapours leaving the saturator at the hottest possible point in this portion of the plant, is insisted on. The amount of sulphate of ammonia produced in the United Kingdom is shown in the following table:—

	1895.	1894.	1893.
	Tons.	Tons.	Tons.
Gasworks	119,645	113,634	112,179
Ironworks	14,588	16,075	8,833
Shale works	38,335	32,891	28,185
Product-gas, coke, and carbonising works.	7,083	3,448	3,265
Total	179,651	166,048	152,762

Considerable progress has been made in the recovery of ammonia from blast furnaces where coal is used, costly and extensive plant being erected for the purpose. It is estimated that the tar, ammonia, and light oils (including benzol) recoverable from the consumption of 14,300,000 tons of coal used in the annual make of pig iron in coke-fired blast furnaces, would be worth three and a half millions sterling. Proposals for the extended use of sulphate of ammonia in agricultural industries are referred to, the introduction of beet-root cultivation in this country being recommended, as well as the home manufacture of glucose from potatoes.

The production of superphosphates in this country is nearly a million tons; the same in the United States; in Germany, 800,000 tons; in France, 750,000; in Belgium, 300,000; in Denmark and Holland, 200,000; and in Italy, 50,000 tons, worth altogether, ten millions sterling, in addition to which nitrates to the value of eight millions, ammonia to the value of two and a half millions, and other fertilisers to the value of two millions; in all, between twenty-two and twenty-three millions are used.

The number of works registered under the Act in England, Ireland, and Wales, is 1,065, besides 126 works registered in Scotland. The number of processes exceeds the number of the works. Many details are given respecting the processes used in minor works for the condensation of acid gases. Such condensation is especially difficult in Venetian-rod works, and experiments have been conducted as to the amount of acidity removed by scrap-iron towers.—E. S.

Sulphuric Acid, Use of Lunge-Rohrman Towers in Manufacture of. H. H. Niefenführ. Chem. Zeit. 20, (1896), 31—33.

The object of the Lunge-Rohrman tower in the sulphuric acid manufacture is, in the first place, to diminish the chamber space necessary for any given output, and, finally, to replace the lead chamber altogether. The author gives his experience with towers built for the first of these purposes.

Sometimes the tower is placed immediately behind the Glover tower, usually between the chambers, and less frequently in the latter half of the plant. It is not advisable to place the Lunge tower in front of the chambers, since, at this point, a small amount of chamber space does relatively a large amount of work; and further, in this position, there is danger of accompanying arsenious and arsenic acids, and even flue dust, blocking the holes in the plates. The

appreciable rise in temperature which must necessarily result, further destroys the lead portions of the apparatus and causes loss of nitre; the author states that a works arranged in this manner has derived no advantage from the tower.

On the other hand, manufacturers who have used a tower in the middle or last portion of the chamber space have obtained increased outputs ranging from 10—45 per cent., the use of nitre remaining as before, or in some cases being greater or less. The author draws attention to the great differences existing in works, in the amount of chamber space per 1 kilo. of sulphur burnt, the size of the chambers and their number, the distance traversed by the gases and the rate at which these are drawn through the apparatus. On account of these differences he finds it impossible to give absolute values for the work of each plate or plate-layer, in a Lunge tower. His experience, however, shows that in badly constructed works the full value of a tower is not obtained, since part of its performance is absorbed in correcting mistakes in the other portions of the plant. He gives the following details obtained from works in which

the towers were placed in the middle of the respective systems:—

(1.) The arrangement consisted of two equal chambers of 2,680 cb. m. total capacity, the ratio between cross-section and length being good (length approx. 59 m.). Under ordinary conditions the daily consumption of Sicilian sulphur was 1,500 kilos., and the kilns burnt this with their normal draught. On placing a Lunge tower between the chambers, the daily conversion rose to 2,300 kilos. of sulphur, i.e., the chamber space per kilo. of sulphur burnt in 24 hours fell from 1.8 to 1.16 cb. m. The increased distance travelled by the gases allowed of increased draught, and this again enabled the kilns to burn the greater quantity of sulphur necessary.

(2.) The capacity here reached 1,080 cb. m., which was divided between four chambers; the total length of these, however, was only 24 m. A daily consumption of 750 kilos. of sulphur was increased to 900 kilos. by the introduction of a tower. The construction of the system rendered normal working difficult; the use of the tower made the working more regular, at the same time increasing the

output; it did not, however, compensate for lack of chamber length.

(3.) Here again the capacity was 1,080 cb. m., but the plant was better constructed, its length being 39 m. As in 2, difficulty arose at the Gay-Lussac tower. 800 kilos. of sulphur, as pyrites, were burnt daily, and this rose, with the use of the tower, to 960 kilos.

The chamber space in this case is therefore 1.12 per kilo. of sulphur. Increase in the number of the pyrites burners would have given a still better result. A diminution in the nitre required, was proved to have occurred in this factory with the introduction of the tower.

These examples give no absolute figures for the value of the towers, but they show that one use of these is to correct errors in the construction of existing plant, and the author has found that any grave mistakes may be rectified when a suitable tower is introduced in the proper position. He also points out that in nearly all cases, the maximum yield is not obtained from the system, the cool chamber space at the back of the tower doing but little work. This might be altered, it is thought, by increasing the pyrites kilns or condut pipes, or by other known means.

An early objection to the use of the towers was that the vitriol obtained from them contained nitric acid. This fault does not occur if the feed acid be of proper strength, 30—42 B $\frac{e}{\circ}$; in this case, the outflowing acid is no richer in nitrogen acids than that obtained from a chamber in a similar position in the ordinary system.

Experience has shown that a plate tower cannot replace the Glover tower; the flue dust from the pyrites kilns blocks the holes in the plates, and the frequent cleansing of these, even if possible without breakage, would interfere too much with the working of the process. One or two layers of plates with larger holes might, however, prove of advantage if fixed on the top of an ordinary tower.

On the other hand, the Lunge-Rohrmann apparatus has given splendid results when used as a Gay-Lussac tower. In two instances the author has replaced the first of a series of two Gay-Lussac towers, in a system of about 2,800 cb. m. capacity, by a plate apparatus 1.6 m. in height, and with this has done exactly the same work as when previously a coke column of 8 m. had been employed; that is, a saving of four-fifths of the absorption height has been effected.

The Lunge towers give a nitrous vitriol of more constant strength, and cause a steadier draught through the whole system. They are specially valuable in districts subject to sudden storms.

The towers have been found useful as denitrating apparatus for the preparation of sulphuric acid free from nitrogen products, such as is used in refining stearin, petroleum, &c. It is here only necessary to conduct a part of the kiln gases through a tower fed with chamber acid of the desired strength.

The author recommends the following combination of the old system with Lunge towers for a new works, from which an output equivalent to a normal chamber system of 3,000 cb. m. is desired:—

The gases proceed from the Glover, through a tube 90 cm. wide, to chamber I, which is 7 m. wide, 6 m. high, and 12 m. long, and allows space for a good initial reaction. Chamber I is connected with the first tower, P 1 , by a 78-cm. pipe. The tower consists of 10—12 plate-layers and each layer contains 12 plates, i.e., here (and in the succeeding towers) the free cross-section is $1\frac{1}{2}$ times that of the entrance tube. From P 1 the gases travel through a 76-cm. tube, to chamber II. (5 m. wide, 6 m. high, and 7 m. long), and from here, by means of a 72-cm. conducting pipe, to the second tower, P 2 . This tower is formed by 16 layers, each of 9—10 plates, and is connected with chamber III, by a 70-cm. pipe, and from chamber III, there runs a 65-cm.

pipe 24 m. in length. This serves to cool the gases before they enter the tower P^6 (18—20 layers of 8—9 plates), which serves as the first Gay-Lussac tower. Behind this is an ordinary Gay-Lussac 8 m. high, filled with coke in the usual manner.

The dimensions have been calculated so as to ensure a uniform flow of gas in the connecting parts whilst diminishing the rate of flow in the towers, thus increasing the duration of reaction here. It is advisable to connect the free end of the Gay-Lussac with a Kötting's hard lead ventilator.

In conclusion the author confirms Lasehe's statement regarding the value of these towers for condensing hydrochloric acid, he himself having obtained good results with hydrochloric acid gas containing admixed sulphurous acid and organic impurities.—J. T. C.

Fatty Acids, Distillation of. E. Sorel. Comptes rend. 1896, 946—948.

FOLLOWING up his work on the distillation of alcohol (this Journal, 1893, 782), the author has examined formic, acetic, propionic, and butyric acids to discover the relationships of distillate to acid distilled, when partial cooling of the vapours before passing out of the retort is prevented. The upper part of the retort was jacketed, so that all the vapour passed over into the neck before condensation, and thus partial condensation (and consequent partial fractionation) on the upper walls of the retort was prevented.

The following abstract table gives the relationship between the distillate and the acid distilled:—

Strength of Original Acid.	Strength of Distillates.			
	Formic Acid.	Acetic Acid.	Propionic Acid.	Butyric Acid.
Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.
1.0	6.7	0.75	1.3	1.5
2.0	1.4	1.5	2.6	3.0
5.0	3.8	4.8	6.4	8.5
10.0	5.0	7.7	12.0	13.6
15.0	7.5	11.5	16.2	16.5
17.2	17.2
18.4	18.4	..
20.0	10.5	15.3	19.6	17.9
25.0	14.9	18.7	20.8	18.5
30.0	17.3	22.1	21.0	18.5
40.0	25.0	29.3	..	18.6
50.0	35.1	37.6	..	21.0
60.0	46.7	46.8	..	23.6
70.0	60.4	57.8

Thus, for acids of low strength, the water in the retort retains a greater proportion of acid the lower the molecular weight of that acid is, but above a certain strength, this state of things is reversed. Propionic and butyric acids of certain strengths (18.4 and 17.2 per cent. respectively) distil over as a whole, without change of strength. Butyric acid between 24 and 34 per cent. strength gives a distillate of constant strength (18.5 per cent.), thus being intermediate between liquids entirely soluble in water and those entirely insoluble therein.—L. T. T.

Cyanogen from Ammonia. Eng. and Mining J. 1896, 61, 449.

EXPERIMENTS have been made by Bergmann on the action of ammonia diluted or not with coal-gas or Dowson gas, on glowing charcoal. At 800° C. only 4 per cent. of the nitrogen supplied as ammonia was converted into cyanogen; at 1,000° C. 24 per cent. was converted. Using a mixture of ammonia and coal-gas, 60 per cent. of the nitrogen of the former appeared as cyanogen at a temperature of 1,180° C. Of the balance (40 per cent.), 29 per cent. was recovered as NH_3 and the remainder was split up into N and H. It is not certain whether the coal-gas acts simply as a diluent or whether its carbon takes part in the reactions. Using Dowson gas rich in CO, to take advantage of the equation $\text{CO} + \text{NH}_3 = \text{CNH} + \text{H}_2\text{O}$ (should it occur), very little cyanide was formed. The results of the experiments are summarised thus:—HCN, and not NH_2CN , is formed when ammonia is passed over red-hot charcoal; the by-products are N and H, and not

CH_4 . The addition of coal-gas increases the yield of cyanogen and decreases the decomposition of the ammonia. "Hydrocarbons of higher molecular weight seem to prevent the decomposition of the ammonia, becoming themselves decomposed, and their admixture is hence not advisable." Carbon monoxide and Dowson gas behave like coal-gas, but favour the decomposition of the ammonia. On the whole, the best yields were obtained with a temperature of about 1,100° C.—B. B.

PATENTS.

Cyanides and Ferrocyanides, Improvements in the Manufacture of, from Sulphocyanides, and the Recovery of By-Products. J. Raschen and J. Brock, Liverpool. Eng. Pat. 10,476, May 27, 1895.

A SULPHOCYANIDE, such as sodium or calcium sulphocyanide, is mixed with or dissolved in four to five parts of water, and the mixture is allowed to flow gradually into a closed vessel containing some water maintained at or near its boiling point. Nitric acid is simultaneously admitted in excess. The vessel is provided with a stirrer and an exit pipe leading the gases evolved to a suitable absorber. The sulphur of the sulphocyanide is oxidised to sulphuric acid, and hydrocyanic acid with nitric oxide and steam pass to the absorber, charged with a solution of a caustic alkali or alkaline earth. A cyanide is thus formed, and air being carefully excluded, the nitric oxide is not absorbed, and is passed on to a suitable apparatus for regeneration as nitric acid, by treatment with air and steam. It is advisable to maintain "a slight vacuum" in the apparatus, to prevent leakage. The solution of the cyanide formed, may be evaporated in a vacuum pan, but, as it is liable to contain a little of the higher nitrogen oxides, it should not be fused, unless such oxides have been removed before the gases reached the absorber. If a ferrocyanide be required, the cyanide solution may be treated with a salt or oxide of iron.—E. S.

Cyanides and Ferrocyanides, Improvements in the Manufacture of, from Sulphocyanides, and the Recovery of By-Products. J. Raschen and J. Brock, Liverpool. Eng. Pat. 10,956, June 1, 1895.

THE process employed differs from that described in the preceding abstract (Eng. Pat. 10,476) in the use of an oxidising agent—such as a nitrate, chromate, lead peroxide, manganese peroxide, or the like, with sulphuric acid—instead of nitric acid, to oxidise the sulphur in the sulphocyanide to be decomposed. As the reaction is rather violent, the oxidising mixture is heated by itself, and the sulphocyanide, in solution or suspension in water, is gradually added. The hydrocyanic acid and other gases and steam evolved, are passed into a solution of an alkali or alkaline earth to form a cyanide, from which, if desired, a ferrocyanide may be obtained. In case a nitrate is used as the oxidiser, nitric oxide will be present in the evolved gases, and the treatment will be the same as that described in the abstract to the previous patent.—E. S.

Concentrating Sulphuric and other Acids, Improvements in Apparatus [Vessels] employed for. R. Wilson, London. Eng. Pat. 14,221, July 26, 1895.

BREAKER-shaped vessels are used, constructed of porcelain, glass, or glazed earthenware, in each of which, behind the lip, a vertical passage or conduit is formed by bending a strip of porcelain or glazed earthenware, while plastic, in the shape of a channel or groove, to the inside, reaching to within about an inch of the bottom. In the system adopted for a plant, the vessels are arranged in steps, so that the acid in each must pass up the channel formed as described, and flow over the depressed lip into the vessel next below, thus ensuring a perfect circulation, the lighter or weaker acid being always at the top.—E. S.

Nitrides and Ammonia, Improved Method for Producing. H. Mehnert, Charlottenburg, Germany. Eng. Pat. 12,471, June 27, 1895.

OXYGEN compounds of such elements as boron, silicon, magnesium, titanium, and vanadium, capable of combining with nitrogen at a high temperature, are exposed to the heat of an electric furnace in the presence of free nitrogen and carbon. A high-tension current must be employed, unless the furnace be fed with coarse pieces of coke and a jet of sand be blown in whilst generator gas is introduced; on entering the hot zone of the electric furnace, "the sand evaporates and then acts as desired." Nitrides thus manufactured may be treated with steam to obtain ammonia, and an oxide from which a nitride may be re-formed as before.—E. S.

Cyanogen Compounds, Improvements relating to the Production of, and to the Preparation of Materials for Use therein. Dr. A. Frank, Charlottenburg, and Dr. N. Caro, Berlin, Germany. Eng. Pat. 15,066, Aug. 10, 1895.

BARIUM carbide, or a mixture of calcium and barium carbide, or of calcium and sodium carbide, is heated to a "dark red" in a retort through which a current of nitrogen saturated with moisture is passed. The resulting mass is lixiviated, any acetylene gas given off is collected, and the cyanide solution obtained may be treated in any well-known manner. Preferably carbonic acid gas is passed into the solution to expel hydrocyanic acid, which is collected and converted into any desired cyanide. If a caustic alkali or alkaline carbonate be added to the carbide treated, nitrogen, free or combined, may be used dry. When it is desired to obtain ferrocyanogen compounds, iron is added to the carbide treated.

In preparing carbides from free metal and carbon, if a volatile metal, as potassium, sodium, or magnesium, be used, the metal is heated with carbon to the necessary high temperature in closed vessels, so that the vapour of the metal may be converted into carbide.—E. S.

Acid Pumps, Improvements in. E. P. Peyton, Birmingham. Eng. Pat. 15,425, Aug. 16, 1895.

THE pistons of acid pumps, under this invention, are made of glass, china, or other material impervious to acids, instead of earthenware, which latter in time admits passage of the acid, whereby the iron rod cemented in the piston and by which it is worked, becomes corroded. Earthenware pistons may, however, be rendered impervious by means of paraffin, wax or resin, applied either in a melted state, or repeatedly, after successive dryings, in solution in a volatile solvent. Or such pistons may be enamelled.—E. S.

Aluminous Ores and Silicious Matters, A New or Improved Process for the Treatment of. W. T. Whiteman, London. From The Compagnie Générale d'Alumine Exploitation des Brevets F. Raynaud (Société Anonyme), Brussels, Belgium. Eng. Pat. 8072, April 16, 1896.

WHEN a mixture of bauxite and sodium sulphide is heated in the presence of steam, sodium aluminate is formed and hydrogen sulphide evolved, thus:—

If sodium sulphate be added to the mixture, sulphur is set free—

Replacement of the alumina by silica in the mixtures, gives soluble silicates, the other products being the same. It is preferred in the first-described process to form briquettes of a mixture of aluminous ore, carbon, and alkali sulphate; after drying, the briquettes are heated in cylinders through which steam is passed, and the H_2S evolved is collected. The fixed product is lixiviated to obtain the alkali aluminate, from which alumina may be precipitated by carbonic acid.

To obtain aluminium sulphide, as a source of aluminium, a mixture of alumina and crushed coke is heated in a current of hydrogen sulphide. The addition of 3—4 per cent. of an alkaline or alkaline-earthly oxide to the mixture facilitates the reaction. Or aluminium sulphate is reduced by hydrogen sulphide "in presence of carbon, oxides, sulphates, or sulphides." The aluminium sulphide, obtained by either process, is mixed with 5 per cent. of lead sulphide, and with lead sulphate equivalent to the sulphur in the aluminium sulphide. On heating the mixture to bright redness, "the sulphide of lead reacts on the sulphate of lead and forms sulphurous acid, which is set free in a pure state, and metallic lead which, acting on the sulphide of aluminium, seizes upon its sulphur and oxidises it by means of the sulphate of lead, thus re-forming a fresh quantity of sulphurous acid and metallic lead, which continues to absorb the sulphur of the aluminium, while the latter is not in the metallic state. A small amount of sulphide of lead is, therefore, sufficient to reduce large quantities of sulphide of aluminium, and thus the use of metallic lead is avoided." This process is claimed as yielding simultaneously, aluminium and sulphurous acid.—E. S.

VIII.—GLASS, POTTERY, ENAMELS.

Aventurin Glass. H. Mäckler. Thonind. Zeit. 1896, 20, 220.

THE author finds that normal glass of the composition 3SiO_2 , 0.25 K_2O , 0.25 Na_2O , 0.50 CaO when treated with varying proportions of Cu_2O and FeO at a temperature above the fusing point of felspar (cones 10—12 of Seger's series) yields aventurin. For lower temperatures, 0.75 SiO_2 can be replaced by 0.75 B_2O_3 and 5 per cent. Cu_2O and 5 per cent. FeO may be added. The glass cannot be successfully used as a glaze even when heated on the ware together with reducing agents, such as graphite and powdered iron, zinc and tin, in a reducing atmosphere. The production of iron oxide aventurin is easier than that of the material obtained with chromium or copper. By the use of about 20 per cent. of iron with the boric acid glass already mentioned, the author obtained at about the melting point of silver (Seger's cone, No. 09), a transparent yellow glaze containing many golden flakes. The rationale of the separation is to be found in the work of Ebell, who ascertained that in a glass supersaturated with Fe_2O_3 , the greater part of the iron oxide became converted into the more stable compound Fe_3O_4 . Thus, 100 grms. of this glass, treated with 12.9 grms. of FeO and 14.3 grms. of Fe_2O_3 (each corresponding to 10 grms. of iron) gave a fine aventurin glaze. The glaze showed hair-cracks on white ware and a red ware was therefore used, containing 50 per cent. of true clay substance, 45 per cent. of quartz and 5 per cent. of felspar. The ware was fired at the temperature indicated by Seger's cone No. 7, and glazed at that corresponding with No. 09.—B. B.

Enamels. O. Emmerling. Ber. 29, 1549.

THE author, on examining a French enamel, characterised by its extreme whiteness, found, in addition to silica and potash, quantities of lead oxide (52.51 per cent.) and of arsenic acid (3.74 per cent.) but no oxide of tin, the usual colouring matter, or boric acid. The enamel was easily attacked by dilute acids and was therefore, in the author's opinion, unsuitable for use.—H. I.

Ceramic Stone obtained by Devitrification of Glass. Garchey. Comptes rend. 122, 1277.

See under IX., page 545.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Porous Bricks from Bituminous Coal Shale. Dingler's Polyt. J. 1896, 300, 168.

THE bricks are made from the refuse of the coal washers at the "Libuschin" pit, near Kladno, in Bohemia, mixed with an appropriate quantity of clay. They are burnt in ring ovens, and are clinkered throughout, showing small blue fused particles, which seem to impart to the brick resistance to pressure and weather. Both these qualities are reported to be very good.—A. G. B.

Ceramic Stone obtained by Devitrification of Glass. Garehey. Comptes rend. 122, 1277—1278.

GLASSES containing an excess of lime, alumina, or magnesia are the most easily devitrified. The inventor uses bottle glass, which is reduced to powder, placed in a mould, and heated, first to a moderate temperature until pasty, and then for a few minutes in another furnace to a high temperature. The completely devitrified material is then stamped and pressed. The product has the appearance of a building stone.—V. C.

See under XXIII., page 559.

PATENTS.

Slurry, Improvements in Arrangements for Drying by the waste Heat from Cement Kilns. W. Joy, Snodland. Eng. Pat. 12,391, June 26, 1895.

THE cement kiln, the waste heat of which is to be utilised, communicates with a drying chamber, above which is a second chamber in connection with the first, and with the chimney. The roof of the second and upper chamber is formed of metal plates, constituting an open slurry-drying floor. A third super-imposed chamber may be used, and the drying flues may be rectangular or arched in section.—B. B.

Wood and the Like, An Improved Substitute for. C. A. Allison, London. From the Marquette Mosaic Co. (Incorporated). Montclair, New Jersey, U.S.A. Eng. Pat. 13,073, July 6, 1895.

WOOD pulp is mixed with asbestos or "steel wool," and a colouring matter such as Venetian red, and the mixture is made into a stiff paste with a solution consisting of bi-chromated gelatin, 20 parts, silicate of soda, 70 parts, "soda tungstate," 10 parts. The surplus moisture is drained off in a perforated mould, and the finished product is sprinkled with calcined carbonate of magnesia. The goods are ultimately pressed hydraulically, dried, grained and varnished (if for outdoor work). The material is said to be fireproof.—B. B.

Cement, the Manufacture of an Improved Waterproof Elastic. W. W. Cabena, London. Eng. Pat. 13,648, July 16, 1895.

100 lb. of old paint skins are boiled at a moderate temperature with 1 gall. of raw linseed oil, and after cooling, the mixture is coloured and bodied up with yellow ochre and lamp black. If lumpy, it may be ground. It is claimed that the cement is elastic and waterproof, and that as it will neither shrink nor crack, it is specially suited for flashings, and for repairing gutters, &c.—F. H. L.

Artificial Stone, Vitreous; Manufacture of. A. Hirsch, Paris, France. Eng. Pat. 14,187, July 25, 1895.

FRAGMENTS of glass, porcelain, igneous rocks, &c. are packed in moulds lined with some refractory substance, e.g., talc, and heated until adherence by partial fusion has occurred. The mould with its contents is annealed, and its surface smoothed or roughened as may be required. Tesserae may be produced by the use of metal partitions.

A smooth under surface for the block or plate may be obtained by placing fragments of some fluxing material, e.g., "fluorspar or fluosilicates," at the corresponding portion of the mould.—B. B.

Artificial Stone, Improvements in the Manufacture of and Apparatus therefor. W. P. Thompson, London. From La Société Anonyme la Néo-Litho, Moll, Belgium. Eng. Pat. 3799, Feb. 19, 1896.

A MIXTURE of lime and sand, containing about 10 per cent. of the former, is filled into moulds and subjected to the action of steam under a pressure of 2—3 atmospheres, afterwards increased to at least 5 atmospheres. The apparatus used consists of a frame, constituting the mould, and a high-pressure cylindrical boiler with interior perforated tubes for the supply of steam, and of rails whereon the mould is run into the steam space.—B. B.

X.—METALLURGY.

Phosphoric Iron Ores in the Blast Furnace, Effect of Additions of Titaniferous Ores to. A. J. Rossi. Eng. and Min. J. 61, 1896, 516.

THE author has endeavoured by a few experiments, with from 200 to 500 grms. of ore, to ascertain whether by mixing titanite and phosphoric iron ores together previous to smelting, the weakening influences of the phosphorus on the metal, when obtained from the latter ore alone, might in any way be counteracted. With phosphoric ore a grey metal was obtained containing 2.862 per cent. of phosphorus and which broke easily, whereas with the mixed ores a grey large-grained metal containing 3.98 per cent. of carbon, nearly all graphitic, 3.229 per cent. of phosphorus, and 0.4 per cent. of titanium, was produced, which withstood several blows before breakage.

It would also appear from these experiments that whilst titanium in an iron ore has a tendency to throw the carbon in the metal produced therefrom into the combined state, the united effect of phosphorus and titanium is to produce a metal in which nearly all the carbon is in the graphitic state, this effect being the greater as the quantities of phosphorus and titanium in the mixtures increase.—A. W.

Fusion Process, The Morosco [with Molten Lead]. Eng. and Min. J. 61, 1896, 495.

THIS process for the extraction of precious metals from calcined ores by bringing them into contact with molten lead is now said to be practicable, the engineering difficulties having been overcome. A plant has been set up at Amador City capable of working 10 tons per day, and giving yields of over 90 per cent. extraction with gold-bearing sulphides and base ores.

THE fine ore, after roasting to get rid of sulphur, arsenic, antimony, &c., whilst at a temperature above the melting point of lead, is automatically fed in a steady stream to the bottom of the bath well. It at once attempts to rise through the bath of molten lead, of over 5 tons, but is met in its upward course by circular perforated plates with arms between, by which it is caught and thrown on to another set of stirrers and so on five times. When it reaches the surface it is discharged automatically by a rapidly revolving disc and passed into a trap box of running water, by which it is cooled before passing to the concentrator. The gold and silver will have alloyed with the lead in the well, and the freed ore, which carries about 44 per cent. of lead with it, is treated for the recovery of the lead in the concentrators.

—A. W.

Silver, Volatilisation of, in Chloridising Roasting.

L. D. Godshall. Eng. and Min. J. 1896, 61, 469—470.

THIS is a reply to criticisms made by Stetefeldt, of a former paper of the author's. In this paper it was asserted that siliceous ores containing more than 6 per cent. of silver can be better chloridised in some furnace other than the Stetefeldt; and that ores containing much lime (15 to 20 per cent.) are also with difficulty roasted in this furnace unless sufficient sulphur be present to convert the whole of the lime into CaSO_4 , and even then the chloridisation

rarely exceeds 60 per cent. Often only 15 to 20 per cent. of the silver is chloridised in the body of the furnace, although about 65 per cent. of the ore may have been roasted; yet, after lying upon the cooling floor of the furnace for three days, the silver in the ore may become chloridised up to 90 per cent.—W. G. M.

PATENTS.

Metallic Alloys, Improvements in the Manufacture of. J. C. Bull and E. M. Lagerwall, Southwark. Eng. Pat. 10,671, May 29, 1895.

The alloys referred to are those known as "white metals," which are composed of lead as a base, combined with tin, antimony, and the like.

A small proportion of an alloy of mercury with tin or lead is added to the molten "white metal" for the purpose of improving its grain, texture or hardness.—J. H. C.

Lead, Silver, Gold, and other Metals, Improvements in the Extraction of from Galena or Sulphides of Lead and Zinc, and from Mattes and Refractory Ores. H. E. Fry, London; J. David, Swansea; and C. Le Doux, Morriston. Eng. Pat. 12,452, June 27, 1895.

The sulphides, mattes, or ores after agglomeration, if necessary, are smelted in a cupola furnace with a flux composed of nitre-cake or other form of bisulphate or sulphate of soda and burnt pyrites, or other form of iron oxide, by which means metallic lead containing the gold and silver, is obtained. Any matte which separates from the liquid slag is collected for subsequent treatment, by roasting and re-smelting or otherwise.—J. H. C.

Iron and Steel, Improvements in the Hearths or Bottoms of Mill and other Furnaces for Heating. A. E. Tucker, Birmingham, and F. W. Harbord, Egham. Eng. Pat. 13,050, July 6, 1895.

The hearths or bottoms are made of a mixture of basic slag and blast furnace slag with, sometimes, an addition of limestone or dolomite.—J. H. C.

Slimes from Ores of Precious Metals, Improvements in Treating. M. Crawford. From R. Keck, Colorado Springs. Eng. Pat. 13,536, July 13, 1895.

Chloride of sodium is added to the cyanide or other solvent employed to facilitate the subsequent filtration and precipitation.—J. H. C.

Gold and other Precious Metals, A Process for Precipitating from Solutions used for Extracting such Metals from their Ores. M. Crawford, Colorado Springs. Eng. Pat. 13,537, July 13, 1895.

The solutions are filtered through granulated charcoal, prepared by saturating it with solutions of alumina, iron, copper, or zinc, with the addition of silicate of soda. The charcoal is subsequently dried, heated to redness, and when cool is ready for use.—J. H. C.

Metals having Different Melting Points, An Improved Method of Separating. H. Lange, Duisburg. Eng. Pat. 23,114, Dec. 6, 1895.

The claim is for "the separation of the different metals forming metallic mixtures, by melting one or all of such metals in fractions or successive stages in a heated fluid [such as melted paraffin] with or without the employment of pressure, or by means of a superheated gas."—J. H. C.

Heating Metal [Iron]. Improvements in and relating to Furnaces for. W. H. Bailey, Piqua, Ohio, U.S.A. Eng. Pat. 4776, March 3, 1896.

This specification describes a double furnace intended for the heating of bars or billets and of sheets, in separate chambers. The flame from the grate plays over a low fire-bridge into a somewhat lofty heating chamber for the reception of the bars, thence over a second high fire-bridge it has access to a larger chamber used for reheating the sheets. The chimney is placed at the far end of the second chamber, and is connected by separate flues with the top of the first chamber and with the bottom of the second. When in full operation, the former flue is closed by a damper, so that the heated gases after passing obliquely upwards across the first chamber, pass diagonally downwards through the second.—W. G. M.

Gold, Apparatus for Separating and Saving. J. Mait, Oakland, California. Eng. Pat. 6242, March 20, 1896.

AURIFEROUS ore, wet or dry, is passed over a sloping metal table, which is kept in constant motion by a lateral oscillation, combined with a vertical "bumping" action. In traversing this table the material passes over a number of transverse troughs in each of which is supported a rake-like row of spoons. The gold thus has the opportunity of separating by gravity in the bottoms of the grooves.

—W. G. M.

Steel, Improvements in the Manufacture of. F. B. East, Landore, and J. R. Wright, Gowerton. Eng. Pat. 7272, April 4, 1896.

AIR or steam, or a mixture of the two, is blown through the bath of metal in an open hearth furnace, by means of cast-iron pipes attached to a swivel joint, and with flexible connections outside the furnace. The pipes are protected by a refractory coating, and deliver the blast at suitable pressure through wide orifices.—W. G. M.

Iron, Improvements relating to the Purifying and Refining of, and Apparatus therefor. H. H. Lake, London. From The Hawkins Steel Co., Detroit, U.S.A. Eng. Pat. 8946, April 28, 1896.

IRON containing a low percentage of carbon is melted in a cupola and allowed to fall in a gentle stream, or in a thin sheet, upon the hearth of a reverberatory furnace through a vertical chamber, of which the fire-bridge forms one wall. Here it passes through the flame playing from the grate to the hearth, and is subjected to the action of blasts of air and superheated steam delivered through different tuyères. The metal thus nearly decarburised, is collected on the hearth of the puddling chamber, and is worked (preferably with oak saplings) to remove all slag, and to ensure thorough puddling to a point short of balling.—W. G. M.

Tin and Terne Plates, Improvements in the Method of, and Apparatus for Preparing. J. D. Grey, Tondou, Glamorganshire. Eng. Pat. 8959, April 28, 1896.

IN lieu of black-annealing, the pickled and washed plates, contained in the washing rack, are transferred to a truck, which is drawn slowly through a drying furnace by means of an endless chain driven by a sprocket wheel. After this treatment, the plates are cold-rolled singly, white-annealed, and finished in the usual way.—W. G. M.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A.)—ELECTRO-CHEMISTRY.

PATENTS.

Acids and other Corrosive Liquids, Process for Preventing the Chemical Action of on Metal Containers, Conduits, and the Like. C. A. Jensen, London. From A. Sinding-Larsen, Christiania, Norway. Eng. Pat. 12,320, June 25, 1895.

THE object is to dispense with protective linings, and yet to prevent corrosive action. This is done by making the vessel a cathode, supplied with current from without, the anode being immersed in the liquid, and made of a material chemically indifferent.—J. C. R.

Electrical Batteries, Secondary; Improvements in the Manufacture of Positive Plates for. C. H. Weise, Poessneck, Germany. Eng. Pat. 12,417, June 27, 1895.

THE plates, coated with the lead oxide, are immersed in a bath of glycerin, where they harden, with the development of considerable heat and gas. If the hot plates after this are placed in a solution of sulphuric acid of sp. gr. 1.15, the hardness further increases as long as gas is developed. Plates thus treated are easily formed, and have a high capacity, in spite of their hardness. Plates which are practically worn out and have porous surfaces may be similarly treated and hardened.—J. C. R.

Electric Arc Lamps [Retarding Oxidation of Carbons], Improvements connected with. A. C. Seibold, Mount Vernon, E. O. Clark, and W. Sowdon, New York, U.S.A. Eng. Pat. 13,207, July 9, 1895.

It is proposed to diminish the combustion of carbon electrodes by excluding oxygen from the arc by means of a close-fitting translucent globe or shell surrounding the contiguous ends of the electrodes. To prevent the obstruction of the light by the particles of carbon thrown off, and which settle upon the inner wall of the surrounding or enclosing shell or globe, a cylindrical guard (wire gauze) is introduced within the enclosing globe.—J. C. R.

Secondary Batteries [Electrodes], Improvements in or connected with. F. King, London. Eng. Pat. 17,821, Sept. 24, 1895.

TO avoid the rapid formation of sulphate on the surface of the plates when enclosed in porous or perforated diaphragms (consequent on the rapid lowering of the specific gravity of the electrolyte immediately underneath such diaphragms or envelopes), the inventor makes a number of perforations, passages, or pipes extending through the grid or support and finished plate, preferably conical in shape. These perforations or passages are unoccupied by active material or material to be rendered or become active. Eng. Pats. 1731 and 2816 of 1895 are referred to (this Journal, 1896; 121).—J. C. R.

Electrode, A New or Improved Porous Plate, Body, or. W. H. Beck, London. From J. Johnson and J. H. Robertson, Brooklyn, New York, U.S.A. Eng. Pat. 17,825, Sept. 24, 1895.

THE improved electrode is made by mixing an inert, porous, non-conducting substance, preferably pumice stone, with about an equal bulk of molten lead, so that the air contained in the porous substance expands and forms air spaces in the metal. The pasty mass is moulded to the required shape, and the plates are formed in the usual way. A small quantity of either tin or bismuth may be added to the lead in order to lower its melting point.—G. H. R.

Filling Paste of Accumulator Batteries [Aloine Paste], Improvements relating to the Composition of. R. Linde, Berlin, Germany. Eng. Pat. 3091, Feb. 11, 1896.

THE improved filling is made by kneading a solution of aloine or its homologues, in water, alcohol or ether, into a

paste with the lead oxides. It is claimed that aloine forms with lead oxide an almost insoluble salt, which is not decomposed by oxidation during charging, but gives rise to an oxy-acid which binds the active material together, and is also electrically conductive.—G. H. R.

Metallic Sulphides, Process for Working. A. von Siemens, Berlin, Germany. Eng. Pat. 7123, April 1, 1896.

THE fact that the sulphides and sulph-hydrates of the alkaline earth metals form soluble double salts with the sulphides of antimony, arsenic, and mercury, is taken advantage of to employ their lyes for the extraction of these metals from their ores, and the solution so formed can be electrolysed without the use of a diaphragm. The sulphuretted hydrogen, which is given off during the extraction, corresponding to a portion of the sulphur contained in the ore, and that which is given off during electrolysis, corresponding to the remainder of the sulphur, is collected. After all the metal has been deposited, the bath, which contains calcium sulphide, is treated with carbonic anhydride, and the calcium is precipitated as carbonate together with half the sulphur, whilst the remainder escapes as sulphuretted hydrogen and is collected. The calcium carbonate is converted into caustic lime by heating to redness in the absence of air, whilst the sulphur is distilled off, and the carbonic anhydride is ready for use again. The caustic lime and the collected sulphuretted hydrogen are used for the production of fresh calcium sulph-hydrate, thus not only is the whole of the extraction lye regenerated, but the whole of the sulphur in the ore is converted into a useful form. The process is described with reference to the sulphide of antimony, but is also applicable to the sulphides of arsenic and mercury; care being taken in the latter case that the alkaline sulph-hydrate is in excess.—G. H. R.

Electrodes for Accumulators, Improvements in. W. Majent, Berlin, Germany. Eng. Pat. 8695, April 24, 1896.

ROOM for the expansion of the active mass is provided by leaving a hollow space between it and its enclosing frame. This space is formed by placing within the metallic frame a sufficiently thick layer of sugar, salt, sulphate of soda, or other substance soluble in water, and then filling in the active material, and, after the latter has hardened, the soluble substance is dissolved out.—G. H. R.

(B.)—ELECTRO-METALLURGY.

Nickel Plating, Exciting Salts for. G. A. Le Roy. Rev. de Chim. Ind. 1896, 7, [75], 70—71.

THE author has examined four samples of "exciting salts" used for increasing the conductivity of the nickel sulphate solution and obtaining a bright adhesive deposit of the metal. They consisted of:—Ammonium sulphate; ammonium sulphate (98 per cent.) and citric acid (2 per cent.); common salt (85 per cent.) and water (15 per cent.); and, common salt (75 per cent.), boric acid (5 per cent.), citric acid (5 per cent.) and water (15 per cent.).—E. B.

Mercury, Electrolytic Estimation of. E. F. Smith and D. L. Wallace. J. Amer. Chem. Soc. 1896, 18, 169.

See under XXIII., page 569.

PATENTS.

Electro-Plating Ships, Vats, and other Articles; Improvements in and relating to. J. H. Cox, Greenock. Eng. Pat. 10,696, May 30, 1895.

THE object is to coat vessels and other articles which are too large for immersion in an electrolytic bath. The main feature is employing a "belly-band" form of electro-plating bath rendered electrolyte tight by external pressure derived from marginal iron straps fixed temporarily to the vessel. The joint is made with india-rubber cords.—J. C. R.

Metallic Oxides, A Process [Electrolytic] for Reducing certain, by Means of Amalgams of Alkaline Metals. L. Mond, London. Eng. Pat. 12,018, June 20, 1895.

SODIUM or potassium amalgam is employed as a reducing agent for oxides soluble in caustic alkali. Oxide of zinc

in caustic soda is cited. The amalgam is made to form a couple with a cathode of iron or zinc, by being joined up therewith in the electrolyte directly or by a conductor external to the solution. The sodium is oxidised and the zinc is deposited on the cathode, which, to obtain sound and pure deposits, is preferably kept in motion during the action. Part of the caustic soda obtained may be concentrated to solid caustic soda or otherwise utilised, whilst the rest may be used for solution of zinc oxide. A motor or amalgam-producing electrolytic cells may be placed in circuit with the amalgam-decomposing cells. These may be reinforced by current derived from an external source. "In operating, as described, for the oxidation of the sodium and the reduction of the zinc, there is no evolution of hydrogen, and consequently there is no loss of mercury, nor any noxious effects, such as occur where vapour of mercury is carried off with hydrogen."—J. C. R.

Electro-Deposition on Strips, Wire, and like Metal Articles; Improvements in and connected with. Cowper-Coles Galvanising Syndicate, S. O. Cowper-Coles, London, and W. P. Routh, Sutton, Surrey. Eng. Pat. 11,547, April 13, 1896.

This apparatus consists of a number of tanks connected together by tubes which enable the electrolyte to pass from one to the other, and also serve as anodes. The wires or strips to be plated are led from the reels or swifts on which they are wound, and are guided to or from the vessels and through the intervening tubes and passages by rollers, and are kept out of contact with the tubes by perforated supports. As the wires leave the tank they are furnished by passing them between rollers, and are then wound on to another reel. The swifts consist of drums mounted on a spindle, the lower drum having a flange to support the lower coil of wire, and there being between the drums, and secured to the spindle, a piece carrying pins to support the upper coils. When the lower coil is exhausted, these pins can be removed, allowing the upper coil to take its place, and when a fresh upper coil is mounted they are replaced to support it. The brushes by which the electric circuit is completed are made of any conductive material, such as the metal to be deposited, and are arranged to clip the wire and press on it. They are covered with rubber where not in contact with the wire.—G. H. R.

XII.—FATS, OILS, AND SOAP.

Wool Grease, On the Composition of. L. Darmstaedter and J. Lifschutz. Ber. 29, 1174.

This substance $C_{10}H_{20}O$, formerly described as an alcohol, on fuller investigation (this Journal, 1895, 14) turns out to be the lactic decomposition product, $C_{30}H_{50}O_8$, of a new acid $C_{30}H_{50}O_9$, lanocerinic acid. The alcoholic nature of the compound $C_{10}H_{20}O$ appears likewise doubtful. The lanocerinic acid is obtained by saponifying wool-wax, extracting the saponified substance first with petroleum spirit and then with alcohol. The residual soap obtained, is dissolved in dilute alcohol and carefully decomposed with dilute hydrochloric acid. The lanocerinic acid thus obtained is almost insoluble in water and cold alcohol, but is easily soluble in hot alcohol, from which it crystallises in very small plates; m. pt. 104°—105° C. The fused acid contains the elements of 1 molecule of water less than the original substance, and on boiling with dilute inorganic acid, forms an oil which solidifies on cooling, and no longer possesses acid properties. This substance is the above-mentioned lactone. It no longer combines with alkalis; m. pt. 86° C. The extract from the above-mentioned soap, contained in the petroleum ether, seems to consist of alcohols chiefly, three of which have so far been isolated, and one of which is cholesterol (cholesterol).—C. O. W.

Glyceric Acid, New Method of Preparation of. P. Cazeneuve, Bull. Soc. Chim. 1896, 763—764.

This reaction depends upon the fact that glycerin in presence of caustic soda and silver chloride gives glyceric acid, silver, and sodium chloride. The following proportions are employed:—A solution containing 46 grms. of pure glycerin

and 80 grms. of caustic soda (from alcohol) in 500 c.c. of distilled water has added to it 143.5 grms. of silver chloride. The reaction commences in the cold, but is only complete on boiling. The silver chloride turns black and then grey, due to the formation of finely-divided metallic silver. The filtered liquid contains sodium glycerate, sodium chloride, and excess of glycerin, and is evaporated on the water-bath to a syrupy consistency. It is then mixed with 120 grms. of potassium bisulphate, and extracted with acetone free from water. The acetone is distilled in a vacuum to avoid decomposition of the chlorides by the glyceric acid. The residue is treated a second time with pure acetone, and again evaporated in a vacuum, and on the third extraction pure glyceric acid is obtained, only slightly yellowish in colour, and containing a trace of chloride from which it can be freed by means of the lead or calcium salt. The use of pure acetone effects a complete separation from the glycerin, which is quite insoluble in this solvent.—T. A. L.

PATENTS.

Oils and like Liquids, Process and Apparatus for Separating [Impurities] and otherwise Treating. G. Mitchell, London. Eng. Pat. 17,239. Sept. 16, 1895.

This apparatus consists essentially of a siphon, the ascending leg of which is surrounded by a heating chamber. The impure oil is fed into the lower part of this leg, and is raised by means of a vacuum pump placed at such a height above the oil chamber that not even with a perfect vacuum could the oil reach its level. The heat causes a difference between the specific gravity of the oil and of the impurities, such that the latter separate, the oil passing over into the other limb of the siphon, which is continued to a lower level than that at which the oil enters. The impurities, if heavier than the oil, are left at the bottom of the containing vessel, or, if lighter, are drawn up above the oil into a tube forming an extension of the ascending leg of the siphon.—C. A. M.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(A.)—PIGMENTS, PAINTS.

Alizarin Oil, Influence of Composition on the Shade of the Lake Pigments. A. P. Lidow. Zap. imp. russk. techn. obschtsch. 1896, 30, 53.

It is found that the introduction of halogens or a nitro-nitroso group into the alizarin oil exerts no advantageous effect on the resulting colour, but is sometimes positively injurious. The changes of colour resulting when the composition of the oil is modified, tend to show that alizarin oil exerts a chemical action in dyeing, and forms lakes with the dyes and oxides. The fulness of the colour in textiles, when iodised alizarin oil is used, is believed to be due to the low degree of solubility of the fixed oil. On the other hand the introduction of chlorine, or a nitro-nitroso group, renders the oil and lake more soluble.—C. S.

PATENT.

Cement, The Manufacture of an Improved Waterproof Elastic. W. W. Cabena, London. Eng. Pat. 13,618, July 16, 1895.

See under IX., page 545.

(B.)—RESINS, VARNISHES.

Turpentine, Deodorising Oil of. H. Schiff. Chem. Zeit. 20, 361.

The odorous principle is an aldehyde oxidation product of the turpentine, probably represented by the formula $C_{10}H_{16}O_3$. It is formed when the turpentine is stored in an insufficiently closed vessel in a faintly lighted spot, but in

amount does not attain to 1 per cent., on account of its disposition to resinify and cause the oil to dry into a condition in which no reaction occurs on the addition of rosaniline sulphite. The presence of an aldehyde body can be detected by this reagent in the soft resins from various woods. On removing the aldehyde by sodium bisulphite, the oil of turpentine becomes inodorous save for a slight ethereal aroma, but the characteristic smell soon returns when the oil is exposed to air.—C. S.

Varnish [Oil], Improvements in, and in the Mode of Manufacturing the same. E. W. Barnsley, Birmingham. Eng. Pat. 8267, April 20, 1896.

300 GALLS. of old "Baltic" linseed oil are boiled in a copper pan provided with a wire basket containing 60 lb. of pale Turkey umber, the temperature being kept at 230° C. After cooling, 200 galls. are removed and set aside, while the remainder is again heated to 290°–300° C. 84 lb. of gum anime are then melted, mixed with 15 galls. of the thinner oil, the whole diluted with 18 galls. of turpentine, and when cold agitated with 12 lb. of magnesia to every 100 galls. of varnish. After six months, 50 galls. are mixed with five of the thicker boiled oil, and 6 lb. of powdered litharge are sprinkled in and well stirred together. The varnish should be kept another six months at 35° C. before being used.

—F. H. L.

XIV.—TANNING, LEATHER, GLUE, SIZE.

Depilatories, Chemistry of. J. von Schroeder and W. Schmitz-Dumont. Dingler's Polyt. J. 1896, 300, 161–168.

A SAMPLE of liquor from an old, well-plunged lime-pit in a tan-yard was found after filtration through sand, to have a specific gravity of 1.0046 at 17.5° C., and showed a feeble reaction for albumin. The total nitrogen was determined in 100 c.c. by the Kjeldahl method, and the difference between this value and the nitrogen found in the total solid residue was regarded as the nitrogen in the volatile bases; to avoid destruction of nitrogenous matter during evaporation, sodium bicarbonate was added in quantity sufficient to carbonate the lime in the liquor. The albuminoids were precipitated by feebly acidifying with acetic acid and warming. Volatile acids were distilled in steam after acidifying the liquor with sulphuric acid. Estimation of caustic lime proved difficult on account of the organic matter present. Analysis of the sediment which settled from the liquor before it was filtered gave the following figures:—CaCO₃, 8.22; CaO, 43.99; CaO combined with organic matter, 8.82; and organic matter, 38.97 per cent.

Since this contains so much free lime it was concluded that the liquor was saturated with free lime, in which case it would contain 1.299 grms. per litre at 15° C. When shaken with lime, however, the filtered liquor dissolved a considerable quantity showing that lime had been lost during the filtration through sand.

The following table gives the results of the analysis:—

	Grms. per Litre.
Organic solid matter	11.856
Inorganic " "	3.158
Containing CaO*	2.010
" MgO	0.013
" alkali sulphates and chlorides	1.130
Total nitrogen	1.619
Comprising N in solid residue	1.527
" N in volatile bases	0.122

* After having been shaken with lime the liquor contained—

	Grms. per Litre.
Free CaO	1.290
Combined CaO	1.678
Total	2.977

	Grms. per Litre.
Total precipitate by acetic acid	2.022
Comprising fatty acids	0.044
" ash	0.002
" albuminoids (14.21 per cent. N)	1.976
Nitrogen in filtrate from acetic acid precipitate	1.376
Volatile acids (as acetic acid)	0.480
Organic matter not precipitated by acetic acid (containing 13.41 per cent. N)	9.354

The volatile bases present had the odour of trimethylamine and the volatile acids that of caproic acid. The authors do not think that they have sufficient evidence to enable them to pronounce upon the nature of the albuminous organic matter.

Experiments here described in which lime and sodium sulphide were together dissolved in water, led to the conclusion that each of these two compounds retains its individuality when in solution in the presence of the other; hence it may be deduced that the simultaneous application of lime and sodium sulphide for unhairing, whether in form of a solution or of a paste, is beneficial because each exerts its specific action on hide and hair, not because there is a formation of caustic soda by double decomposition as has been supposed. The lime probably also serves to protect the sodium sulphide from decomposition by any carbon dioxide which may be absorbed.

For the proximate analysis of red arsenic, the authors recommend that the arsenious oxide should be extracted from 20 grms. of the sample by digestion at a gentle heat with 200 c.c. of hydrochloric acid (5 per cent.) for 5 hours; the solution may then be oxidised by nitric acid and evaporated to dryness, the residue being heated at 400° C. for 45 minutes and weighed as arsenic anhydride. To separate As₂S₃ from As₂S₅, 10 grms. of the portion from which the As₂O₃ has been extracted may be shaken at the ordinary temperature with 200 c.c. of ammonia (2 per cent.) until no more arsenic is dissolved; an aliquot portion of the solution is evaporated to dryness and the As₂S₃ weighed. A sample of red arsenic thus examined gave:—As₂S₃, 73.56 per cent.; As₂S₅, 26.11 per cent.; As₂O₃, 0.37 per cent.

To investigate the part played by red arsenic in the mixture of it with lime which is commonly used as a depilatory, 40 grms. of lime and 8 grms. of red arsenic were made into a thin magma with 160 c.c. of water, this magma was heated on the water-bath for one hour, then made up to a volume of 3150 c.c. with water, filtered, and the solution analysed. It was found that 4.13 per cent. of the arsenic, 93.50 per cent. of the sulphur, and 15.25 per cent. of the lime remained in solution. The undissolved residue was brown from the presence of uncombined arsenic, so that the chief reactions may be represented by the equations:—

There is, however, the dissolved arsenic to be accounted for, since calcium arsenite was found to be quite insoluble even in presence of excess of lime. Experiments showed that calcium arsenite reacts with a solution of calcium hydrosulphide, with formation of calcium thioarsenite which passes into solution. Supposing the arsenic to exist in this form in the unhairing liquor, it may be calculated from the foregoing figures that 1 litre of the liquor contains 4.355 grms. of Ca₃(AsS₃)₂, 27.780 grms. of Ca(SH)₂ and 1.299 grms. of CaO. It appears then that the sole constituents of the lime and red arsenic depilatory, which can be considered as active, are the calcium hydrosulphide and the small proportion of calcium thioarsenite, unless, indeed, ammonia and amines developed during the sojourn of the hide in the mixture can dissolve any of the calcium arsenite. This point was settled in the negative by the analysis of a liquor which had been used for three weeks for treating kips, when it was found to contain somewhat less arsenic than it did originally, showing that the amines and ammonia which were undoubtedly present had not rendered the arsenic compounds more soluble. The putrid odour of this arsenical lime liquor seems to contradict the common statement that the function of the arsenic is that of an antiseptic.

It remained to ascertain whether the calcium thioarsenite possesses any depilatory properties. For this purpose arsenious sulphide was dissolved in calcium hydrosulphide solution. In this solution, containing $\text{CaS} \cdot \text{As}_2\text{S}_3$, pieces of raw hide were immersed and kept in stoppered vessels for about a month; none of the pieces were materially altered except that each was coloured yellow throughout; the hair was as firm as before immersion, and the hide as soft and elastic. When exposed to the air the pieces lost their yellow colour, consequent on the decomposition of the thioarsenite, and at the same time the hair was loosened. The same effect was observed in the case of pieces of hide left in the thioarsenite solution in open vessels. There was depilatory action, but it was found to be due to calcium hydrosulphide, for the arsenic had all separated as sulphide and the solution contained $\text{Ca}(\text{SH})_2$.

The authors conclude that the activity of arsenical lines is due to calcium hydrosulphide and calcium hydroxide alone.—A. G. B.

XV.—MANURES, Etc.

Slags, Phosphoric, from the Basic Process. F. Jean. Rev. de Chim. Ind. 1896, 7, [75], 80.

THESE have the percentage composition:—Phosphoric anhydride, 8—23; silica, 7—15; calcium oxide, 34—55; magnesium oxide, 3—20; iron oxide, 12—20; manganese oxide, 4—10.

As their employment for enriching land is increasing, L. Grandean proposes that their sale should be made subject to the following conditions:—First, the amount of phosphoric anhydride present, should be guaranteed within limits of 2 per cent., thus, 18—20 per cent., for instance; secondly, the fineness of the grinding should be 75—80 per cent., as ascertained by testing with a sieve, of mesh 100; thirdly, the price should be based upon the content in phosphoric anhydride.—E. B.

Manganous Ammonium Phosphate, A New Manure. Rev. de Chim. Ind. 1896, 7, [75], 80—81.

THIS compound is, it is said, more useful to plant-life than manganous ammonium phosphate. It consists of ammonia (32 per cent.), manganese (25 per cent.), and phosphoric acid (43 per cent.). It is very sparingly soluble in water (1 part, according to Dummer, dissolves in 31,092 parts of cold water).

To prepare it, a solution of acid calcium phosphate is mixed with one of manganese chloride, and the precipitate, after washing, is heated with a solution of ammonium chloride or carbonate.—E. B.

Bone Meal, Phosphoric Acid in; Relation between the Citrate Solubility and Fineness. Braun. Chem. Ind. 1896, 19, 219—221.

THE phosphates soluble in citrate solution, were determined by the method used by Wagner for basic slags, in a number of samples of bone meal. The total phosphoric acid and the fineness of the samples, were also determined. The results show that the citrate solubility increases with the fineness of the meal, varying from 30 per cent. with 0.2 per cent. of fine meal, to 90 per cent. with 99 per cent. of fine meal. The coarsest samples thus contain a moderate amount of soluble phosphoric acid, whilst with a medium fineness of about 50 per cent., the solubility is 60—70 per cent., an amount reached in basic slag only when the fineness is about 80 per cent.—N. H. J. M.

XVI.—SUGAR, STARCH, GUM, Etc.

Beetroots, Loss of Sugar during the Preservation of. Strohmmer, Sucr. Belge 24, 76.

(SEE also this Journal, 1895, 589.) In order to verify the statement of Heintz that beetroots give off carbon dioxide, the author enclosed some in a glass vessel through which he passed a slow current of air previously freed from carbon dioxide. After contact with the beetroot, the air was passed through weighed potash tubes. The increase in the weight of the latter does not, however, represent the

whole of the loss of sugar, part of which appears to be converted into other carbohydrates. When beetroot was kept for a fortnight in a current of hydrogen, it was found to contain 3.3 per cent. of pentoses whilst ordinary beetroot only contains 2.1 per cent., and according to the author pentoses constitute the first product of the transformation of saccharose. The amount of carbon dioxide disengaged depends partly upon the nitrogenous matters present and is greater in proportion to the quantity of albuminoids. The only condition of preservation is cold, at a temperature of 4.5°, beetroot giving off less than half as much carbon dioxide as it does at 17°.—A. K. M.

Sugar, Inversion of, by Salts. J. H. Long. J. Amer. Chem. Soc. 1896, 18, 120—130.

A NUMBER of experiments are described in which the inversion of cane-sugar is brought about by various ferrous, manganous, zinc, aluminium, lead, cadmium, and mercury salts. Thus, in the case of the syrup of ferrous iodide of the pharmacopœia, inversion takes place slowly, even when the preparation is kept in the dark, and at the ordinary temperature. When exposed to the light, the cane-sugar underwent complete inversion in about 2½ months. The rate of inversion is also increased by exposure to air and to increased temperature. At a temperature of 100°, inversion was complete in less than two hours. A number of the results described by the author appear to indicate that the inversion follows the general law shown by Wilhelmy to hold for the action of weak acids on sugar solutions, and in fact the inversion is attributed to the partial hydrolysis of the salts employed.—A. K. M.

Rhamnose, Anhydrous, Crystallised. E. Fischer. Ber. 1896, 29, 324—325.

THE author points out that the constants, $(\alpha)_D$ and melting point of anhydrous rhamnose, as determined by himself, differ widely from the values which Tanret (Comptes rend. 1896, 26) has more recently communicated.—H. T. P.

Lead Bisaccharate [Biplumbic Saccharate], Preparation of, by the Kassner-Wohl Method and its Practical Use in Industry. C. W., Dingler's Polyt. J. 1896, 300, 94—95.

THE author points out that factories employing this process (compare this Journal, 1895, 978; 1896, 125, 287) for the desaccharification of molasses must work at a loss owing to the present prices, and further that the strontium process can only prosper when the price of molasses is low. There is also the unfavourable relation existing between lead and sugar to be taken into account. Thus 800 parts of lead bisaccharate are formed from 342 parts of sugar, so that 1,000 cwt. of sugar would yield 2,320 cwt. of saccharate. Since the latter contains at least 25 per cent. of water, 3,000 cwt. of saccharate require handling. Furthermore there is a considerable amount of wash-water which Kassner states amounts to seven times the weight of the molasses; of this 1.5 parts of the last washings can be used for washing new saccharate, the remaining 5.5 parts have to be evaporated, and this operation represents a cost of 0.5 mark more per 2 cwt. of molasses than with the strontium process.

The following figures show that the precipitation of lead by hydrogen sulphide approaches completion when the juice has a concentration of 13° to 15° Brix. Juice of:—

	Per Cent.	Per Cent.
40° Brix contains 0.01 PbO; by H_2S 0.01 is precipitated.		
30° "	0.04 "	0.01 "
25° "	0.03 "	0.015 "
15° "	0.027 "	0.018 "
13° "	0.027 "	0.022 "

It follows, therefore, that definite concentrations must be adhered to, which is not the case with the strontium process.

The author does not agree with Kassner that loss of lead is impossible with this process. A factory has to employ 2,400 cwt. of lead oxide to separate 1,000 cwt. of sugar from 2,000 cwt. of molasses, and in this quantity of molasses there are at least 20 cwt. each of potassium chloride and sulphate. It is incorrect to state that the

whole of the potassium sulphate passes away in the lye, as half the quantity combines with the oxide of lead. The equivalent ($\text{KCl} + \text{K}_2\text{SO}_4$): PbO represents a loss of 42 cwt. of oxide of lead on 2,000 cwt. of molasses, equal to 600 marks; the lead chloride and sulphate can only be regenerated at a considerable cost.

Since in this process the lead disaccharate is decomposed by carbon dioxide, from 2,000 cwt. of molasses 2,880 cwt. of lead carbonate result. To this amount must be added the simultaneously precipitated calcium carbonate and 39 per cent. of water, so that at least 4,000 cwt. have to be filtered and dried. If it can be assumed that it is possible to previously dry the lead carbonate by waste gases there yet remain 800 cwt. of water to be evaporated, representing a cost of 0.08 mark per 2 cwt. of molasses. There is in addition the cost of heating 3,000 cwt. of lead carbonate to 250°C . which amounts to 15 pf. per 2 cwt.

Attention is directed to the extraordinarily large quantity of wash-water which Kassner needs for the purification of the saccharate, and even if the capacity of the saccharate and lead carbonate as a ready filtering medium is correct, filter stations on a large scale would be necessary. Experiments on small quantities have confirmed the author's assertion on this point, especially in the case of coincident experiments with "strontia bi-saccharate." If sugar, completely free of lead, can be obtained by the Kassner-Wohl process, it is impossible to prevent the accumulation of lead compounds in the residual molasses, and which in consequence would be useless for any other purpose. In conclusion the author objects to the desaccharification of molasses by the lead process on the ground of its expense, the large amount of fuel required, and the bad yields obtained.—J. L. B.

Lead Saccharate, Preparation of, by the Kassner-Wohl Method, and its Practical Use in Industry. Remarks on C. W.'s Article. G. Kassner. Dingler's Polyt. J. 1896, 300, 118—120.

The author draws attention to a printer's error in his former papers, whereby the compound $\text{C}_{12}\text{H}_{22}\text{O}_{11} \cdot 2\text{PbO}$ was termed "lead bisaccharate" instead of biplumbic saccharate.

Referring to C. W.'s criticisms (see preceding abstract), the author considers that definite conclusions as to the consumption of fuel for the evaporation of wash-waters are at present premature. When working with large quantities, the process would be easier to carry out, for the wash-water (not merely the last washings, as supposed by C. W.) would be continually used for covering new saccharate, and the last washings in place of water for the solution of fresh molasses, in consequence, the remaining amount of water to be evaporated would not be more than three times the weight of the molasses, or possibly even less.

Even if C. W.'s figures be correct as showing that the precipitation of lead approaches completion in juices of a concentration of 13° — 15°B ., he has lost sight of the fact that lead is more easily precipitated as sulphide from solutions of sugar which have been previously made slightly alkaline by lime than if the precipitation take place under neutral conditions and after allowing to stand. Under these circumstances, all the lead would be precipitated from 40 per cent. sugar solutions. For this reason the author suggests the use of calcium sulphide in place of hydrogen sulphide. It is, moreover, known that lead is completely precipitated by saturation, provided that the molasses do not contain invert sugar. Here also an addition of lime is advantageous in the event of a re-saturation being necessary. The author states that in one of his experiments he obtained by saturation a 25 per cent. sugar solution which did not contain an appreciable trace of lead. It would be quite possible to use higher concentrations and so diminish the cost of evaporation to which C. W. objected.

If the removal of small quantities of lead by means of calcium or hydrogen sulphide be objected to on account of unpleasant smell or other disadvantages, the metal may be precipitated electrolytically—a process not applicable for the removal of strontium or barium from solutions of sugar. It is necessary that lime should be added, since sugar is not

an electrolyte. Metallic lead is deposited on the cathode and lead dioxide on the anode.

With regard to the heavy loss of lead resulting from the molasses containing potassium chloride and sulphate, the numbers stated in the preceding abstract are incorrect. It has been overlooked that 2 mols. of KCl combine with 1 of PbO , so that the amount of lead in combination would be 28 instead of 42 cwt. The author (Dingler's Polyt. J., 1895, 298, 65) has not denied the partial deposition of lead due to the reaction between the potassium sulphate contained in the molasses and lead oxide. It may be advisable to allow this deposition to continue undisturbed, for less sulphate would be present in the residual lye, which, when calcined, would yield a more valuable potash. The statement that sulphate of lead is expensive to regenerate is also incorrect, for it is only necessary to treat the saturation mud and other products containing lead sulphate in the cold with some of the manufactured alkaline carbonate, to convert it into lead carbonate. The difference in value between potassium sulphate and an equivalent quantity of potassium carbonate is partly compensated for by the purer potash.

If the objection that the residual molasses contain lead be admitted, there is no reason why its removal should not be brought about by the methods above described. Further improvements are in course of preparation, and the author considers that the method, although issued in an imperfect form, will soon be completed, and the details more fully worked out.—J. L. B.

Yeast, Multiplication of, during the Primary Fermentation of Bottom Fermentation Beer. F. Schönfeld. *Wochen-schr. f. Brau.* 1896, **13**, 421—426.

The experiments described confirm in the main, some results obtained by Mohr (*Wochenschr. f. Brau.* 1886, 216) several years ago. It is shown that the multiplication of the yeast very nearly reaches its limit in three to four days, with an attenuation corresponding with an apparent loss of about 2.5 per cent. of extract. Beyond this, the multiplication is only small and proceeds slowly, reaching its maximum in four to five days with the fermentation of 3.6—5.0 per cent. of extract. Starting with 6.5 to 9.0 cells in a unit volume at pitching, the maximum found during fermentation, varied between 22.1 and 26.6. These results refer to the yeast cells found suspended in the beer. At this stage of the fermentation, however, the yeast begins to deposit, and, taking the deposit into account, a maximum of 28.6 cells was reached in six days. The ratio between the number of cells sown and the yield per unit of volume varied between 1:2.5 and 1:6; this ratio is dependent upon various conditions, but in the main varies inversely with the amount of yeast sown.—A. K. M.

First Runnings and Fusel Oil, Inquiry as to whether the Constituents of, are Products of the Action of Culture Yeasts or of Foreign Organisms. Zeits. f. Spiritusind. 1896, **19**, 136—137.

THE experiments of the authors lead to the conclusion that under certain conditions the culture yeasts employed in distilleries give rise to the formation of amyl alcohol without the co-operation of bacteria; in certain cases they also produce varying quantities of acetic aldehyde, whilst furfural is also a product of their fermentative action. Neither of these substances is, however, a necessary product. Of these secondary products of alcoholic fermentation, acetic aldehyde is most readily formed, and the authors attribute its formation to the oxidation of ethyl alcohol in the nascent state. Furfural was only found in the products of fermentation by distillery yeasts, when acetic aldehyde was present in considerable quantity. *Sacch. mycoderma D.* gave but little acetic aldehyde, and yet produced furfural, whilst *Sacch. mycoderma b* yielded much aldehyde but no furfural. Amyl alcohol was produced in 8 out of 13 experiments with pure yeasts, and although the conditions of its formation have not been ascertained, the authors consider that the following conditions are connected with its formation, namely, the presence of old yeast cells, a high fermentation temperature and lactic fermentation prior to pitching, although the mere presence of lactic acid is without effect. It is also noticed that where furfural is produced, only very small quantities of acetic aldehyde are present, and this suggests the view that anaerobic conditions favour the production of fusel oil. With regard to valerianic acid and the higher fatty acids formed during alcoholic fermentation, the authors believe that these result from the decomposition of the more complex nitrogenous matters present.—A. PATENT.

Carbonic Acid Gas, Air-free, from Fermentation; Improvements in or relating to the Collection and Utilisation of [Aeration of Beer], and Apparatus therefor. A. J. Boulton, London. From the Pabst Brewing Company, Milwaukee, Wisconsin, U.S.A. Eng. Pat. 3098, Feb. 11, 1896.

THE fermenting vats on the upper tier are of the ordinary open kind, but are provided with removable hoods fitted into their open tops, and suspended from sheaves: a valved tube passes from the top of each hood to a gas main. In the next lower tier the vats are permanently closed, and are connected at the top to branch gas-collecting tubes. A slight pressure is maintained throughout the system above the atmospheric pressure, to prevent in-leakage of air. In the third tier from the top, vats are shown in each of which the hood is adapted at the rim to enter an annular trough external to the vat, the trough being supplied with water, serving as a liquid seal. An extensible gas-holder is provided, a compressor, and a carbonator; also a storage tank, whence beer may be drawn to the carbonator, whence it passes to a filtering apparatus, and thence to a racking bench, to be drawn into shipping kegs. The carbonic acid, before being used to aerate the beer, is passed through purifiers, kept free from air, in which sterilising agents or suitable chemicals are placed; the gas then goes to a condenser provided with a reducing valve, and with a coil through which brine or a cooling medium circulates, whereby moisture is removed from the gas, which is then fit for use in the carbonator.—E. Liquids, Improved Means of Purifying [Sewage]. R. Malabar, Liverpool. Eng. Pat. 8362, April 27, 1895.

A NUMBER of perforated floors are arranged one above another, each floor carrying one or more layers of filtering material. An air space is left between the filtering material on each floor and the floor next above it, and into this space fresh air is either admitted by louvres in the walls or is driven in by means of a fan. A suitable filtering material for sewage or impure water consists of alternate layers of burnt ironstone and fibrous turf. With slight modifications, the same arrangement may be used for filtering mineral or other oils.—L. A.

Precipitating and Filtering Tanks [Sewage], Improved. T. B. Wilson, Manchester. Eng. Pat. 9903, May 20, 1895.

At the bottom of an ordinary precipitation tank, parallel rows of glazed earthenware or concrete pipes, of triangular section are laid, forming, with their edges in contact, a series of V-shaped channels. Abutting against and opposite to perforations in the sides of these basal pipes are the ends of a number of smaller porous or perforated pipes, also of triangular section, arranged in parallel rows, and discharging into the larger basal pipes, at an angle to the horizon of 45°, and extending above the water level of the sewage tank at their upper ends, which are open to the air. A tank filled up with pipes arranged in this manner forms the last of a series working on the continuous-flow system. The precipitate or sludge collects in the V-shaped channels, and the clear filtrate passes into the interior of the pipes, and both are conveyed away by suitably arranged conduits.—L. A.

Separating Solid or Semi-Solid Substances from [Sewage] Sludge or other Fluid or Semi-Fluid Matters, Improved Means and Apparatus for. W. Birch, Manchester. Eng. Pat. 13,857, July 20, 1895.

RELATES to improvements in the apparatus described in Eng. Pat. 6535 of 1892 (this Journal, 1893, 460), whereby the tendency of the endless band to run over the edge of the revolving drum is counteracted, and the motion of the scrapers is made rapid and continuous instead of intermittent.—L. A.

(C).—DISINFECTANTS.

Formaldehyde Gelatin. H. K. van Vloten. Chem. Zeit. 20, 407.

To prepare formaldehyde gelatin in such a form that it can be reduced to a smooth powder which may be introduced into wounds without producing irritation, fine gelatin is dissolved in four times the quantity of water, and the solution placed in a warmed vessel, wherein the necessary quantity of a 40 per cent. formaldehyde solution is stirred in. In this dilute solution the reaction proceeds slowly, so that there is time to beat up the liquid to a foam with an egg whisk. After standing a short time, the liquid portion subsides and the foam, which behaves exactly like dried frothed egg albumin, may be transferred to another vessel before it becomes set.—C. S.

PATENT.

Disinfection, An Improved Method of. D. Sjöström, Stockholm. Eng. Pat. 23,130, Dec. 3, 1895.

FOR the disinfection of articles liable to be damaged by air heated above 100° C., or by steam, the ordinary gaseous disinfectants, such as chlorine, sulphur dioxide, &c. are used, but at temperatures between 50° and 95° (50° to 60° for furs, 80° to 90° for bed-clothes, 65° to 95° for furniture). By this method, less of the gas or vapour is required than by working at the ordinary temperatures, and there is less risk of damaging the articles to be disinfected.—L. A.

XIX.—PAPER, PASTEBOARD, Etc.

Paper (Cellulose), Influence of Temperature and Time Heating on. N. A. Rieszow. Wiestn. obschtn. techn. 1896, 2, 179.

A SPECIAL paper made of flax was examined in a Russian Government laboratory in the following manner:—A comparison was instituted between the paper in its normal state and pieces from the same sheet which had been exposed to definite temperatures for various times. A test piece thus kept for 95 hours at 100° C. had the same tensile strength as the original paper, but its extension became smaller as the water content of the paper decreased. At 110° C., after 7 hours, the strength as well as the extensibility of the paper decreased, and the falling off increased with the length of the test. At 135° C. the paper was still more rapidly injured, and 23 hours' exposure to 143° C. sufficed to diminish the strength about 33 per cent., and the extensibility about 70 per cent. Further experiments went to show that this action of heat obtains with pure paper fibre ("cellulose") and is not sensibly influenced by the treatment with alkali and bleach which the actual paper had undergone.—B. B.

Paper, The Texture of. Abstract from Behrens Mikrochem. Anal. d. Fasern. Papier Zeit. 21 [11], 323.

THE examination of paper by direct reflected light enables one to obtain an idea as to the texture of its surface. Highly glazed paper contains a large quantity of starch-size, and filling materials, which to a large extent hide the fibres from view. These materials are thus removed from the fibre. A strip of paper 10–15 mm. broad and 15–20 mm. long, is moistened with ammonia and then with a few drops of water, after which it is boiled for about 30 seconds. Care should be taken not to derange the fibres and the condition of the solution in which the paper was boiled, will indicate the amount of sizing materials present. After boiling, the ammonia solution is drained off and absorbed by blotting paper and the paper washed with alcohol and gently dried. The examination is performed with reflected light and with a lens magnifying 40–60 times. Considerable difference will be seen between the original paper and that from which the size has been removed, the latter showing numerous irregularities upon the surface and even small holes, passing through the paper. Waterproof and photographic papers, and also paper used for water-colour paintings are exceptions, their texture being even and regular. Machine-made papers show an imperfect parallel arrangement of the fibres in one direction, which accounts for the unequal strength and extensibility when tested lengthwise and crosswise.—S. P. E.

Sizing in Paper, the Effect of Sunlight upon. "B." Papier Zeit. 21, [16], 492.

Animal size renders paper tougher and stronger than rosin size, consequently animal sized paper is more durable and with it an inferior pulp may be employed. The action of sunlight upon rosin-sized paper destroys the effect of the size, making it resemble unsized paper, the action being considered by some to be physical. The author, however, is of opinion that it is due to a decomposition of the size, although the actual chemical change is not clearly understood. From a number of experiments upon various samples of paper, including the best normal papers, which had been made with rosin-size, it was proved that sunlight rapidly destroyed the size and furthermore this destruction was more rapid in the case of highly glazed and satin-surfaced papers than with unglazed papers. The side exposed to the light became like an unsized paper, whilst the unexposed side remained unacted upon sufficiently to prevent ink from being absorbed. A pure animal sized Austrian normal paper withstood the action of the sunlight best. Papers sized with rosin and tannin size withstood the sunlight better than those with rosin size alone, the former being only partially reduced to the unsized condition after months exposure.—S. P. E.

PATENTS.

Paper Pulp, Improvements in Apparatus for treating. L. de Naeyer, Willebroeck, Belgium. Eng. Pat. 12,461, June 27, 1895.

The apparatus consists of a rectangular tank divided into three compartments by two perforated partitions placed lengthwise. The two outside compartments are supplied with stirring plates which are vibrated by means of a rocking shaft. The perforations in the partitions are of such area as only to allow the finely-divided pulp to pass through into the central compartment, when the rough pulp passed into the outer compartments is agitated by the stirring or rocking plates.—O. H.

Paper and Millboard, Improvements connected with the production of Pulp for use in making. E. Davies and H. M. H. Goodfellow, London. Eng. Pat. 3288, Feb. 13, 1896.

SPENT hops are pressed (if not already pressed at the brewery), passed into a horizontal trough containing a conveyor, during passage through which the hops are separated and the seeds loosened from the petals and stalks, thence into an inclined revolving cylindrical sieve, whereby the seeds and dirt are removed, and finally into an ordinary beater for conversion into paper pulp. A blast of air is used to separate the dirt from the seeds.—B. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

Rumex Nepaleusis (Wall.), *Roots of*. O. Hesse. Annalen, 1896, 291, 305—312.

THE plant is common in Madras and in other parts of India and is sometimes used by the natives for medicinal or dyeing purposes. The author describes the isolation of three crystallisable substances from its roots, to which he gives the names Rumicin, Nepodin, and Nepalín, the latter being present in by far the largest quantity.

Rumicin, $C_{15}H_{10}O_4$, is extremely like the chrysophanic acid of rhubarb; it differs from it only in its melting point (186° — 188°).

Nepalín, $C_{17}H_{14}O_4$, forms orange-coloured needles melting at 136° C., which are not volatile, dissolve readily in solutions of caustic alkalis, sparingly in those of alkaline carbonates, and yield a diacetyl derivative.

Nepodin, $C_{15}H_{10}O_4$, forms long brittle greenish yellow prisms melting at 158° ; it is soluble in aqueous solutions of alkaline carbonates and yields a diacetyl derivative. The plants of the genus *Rumex* thus yield a series of bodies different from those obtained from plants yielding rhubarb, the bodies found in the latter being chrysophanic acid $C_{15}H_{10}O_4$, Emodin $C_{15}H_{10}O_5$, and Rhein $C_{15}H_{10}O_6$.—T. E.

Artemisin. Ber. ii d. Jahr. 1894, 3—6.

ARTEMISIN, $C_{15}H_{12}O_4$, is according to Merck obtained from the last mother-liquors furnished in the manufacture of santonin from the seeds of *Artemisia maritima*. It is freed from the santonin by re-crystallisation from chloroform, being deposited combined with 1 mol. of the solvent, which is evolved at 90° . It melts at 200° , gradually turns yellow in the air, and is more readily soluble in water and in dilute alcohol than santonin. Heated with soda 10 parts and acid water 40 parts, a fugitive carmine red colour is produced, and like santonin it gives the same colour with alcoholic soda. Artemisin is apparently a hydroxy-santonin.

Alkaloids, Derived from Certain Species of Cactaceæ. A. Heffter. Ber. 1896, 29, 216—227.

Pellotine.—This alkaloid was described in an earlier paper (this Journal, 1895, 381). The formula then assigned to it is corrected to $C_{17}H_{13}NO_2$. From the mother liquors, the remaining pellotine is conveniently separated as the sparingly soluble double salt, $C_{17}H_{13}NO_3 \cdot HCl$, $HgCl_2$. On addition of mercuric chloride, a resinous precipitate at first appears, from which the liquid should be decanted. After 1—2 days,

the double salt is deposited and may be re-crystallised from boiling water. It is thus obtained in snow-white tabular crystals. Pellotine yields an oily benzyl derivative, but does not furnish a simple methyl derivative. By the action of methyl iodide, there results a mixture of pellotine methyl iodide, $C_{14}H_{11}NO_3I$, and methyl pellotine methyl iodide $C_{15}H_{12}NO_3I$. The latter crystallises from water in colourless prisms—m. pt., 225° C.—and furnishes, when treated with silver oxide, the corresponding ammonium base.

Alkaloids of Anhalonium Lewinii, Hennings, or Lophophora Lewinii, Rusby.

Dried slices (known as "Muscle Buttons") of this plant form a considerable item of trade in Northern Mexico, being utilised by the native Indians for narcotic purposes. Lewin (Arch. f. expt. Path. u. Pharm. 24, 401) was the first to indicate the presence in this drug of poisonous alkaloids; and more recently, the author (ibid. 34, 65) has extracted therefrom two bases, whilst Lewin (ibid. 34, 374) has described a third alkaloid, *Anhalonine*.

By the following process, the author has isolated in all, four alkaloids:—The coarsely powdered drug was repeatedly extracted with 70 per cent. alcohol, and the extract, after distilling off alcohol, filtered, made ammoniacal, and exhausted, at first with ether, finally with chloroform. These extracts were worked up separately. The ether extract was dissolved in water, neutralised with sulphuric acid, filtered, and alternately concentrated *in vacuo* and treated with alcohol, so long as crystals continued to separate. The combined crops were dissolved in boiling water and the solution decolorised by animal charcoal. On cooling, the sulphates of two new alkaloids, differing in crystalline form, were deposited, *Anhalonidine sulphate* in fine felted needles, intermixed with *Mezcaline sulphate* in long lustrous prisms. The main filtrate, deprived of alcohol, was exactly precipitated with barium chloride and again concentrated, as long as crystals could be obtained. The latter were found to consist of anhalonine hydrochloride (Lewin). The mother-liquor, still containing alkaloidal substances, was then mixed with a large excess of alcoholic mercuric chloride. After some time a crystalline precipitate was deposited. This was re-crystallised from dilute alcohol, decomposed by hydrogen sulphide, the solution made alkaline with ammonia, and extracted with ether. The extract, neutralised with hydrochloric acid and evaporated *in vacuo* over sulphuric acid, solidified when covered with absolute alcohol, to a mass of fine needles, consisting of the hydrochloride of a fourth (new) alkaloid, *lophophorine*. No other bases could be detected. The chloroform extract contained almost exclusively mezcaline. The yield of alkaloids was about 1.1 per cent., distributed as under:—Mezcaline, 0.46 per cent.; crude anhalonidine, 0.39 per cent.; anhalonine, 0.22 per cent.; and lophophorine, 0.03 per cent.

Mezcaline.— $C_8H_8N(OCH_3)_3$. The base, obtained by adding ammonia to a solution of the sulphate, and extracting with chloroform, crystallises in small white needles melting at 151° C. It is readily soluble in water, benzene, chloroform, and alcohol, with difficulty in ether and petroleum spirit.

Mezcaline Sulphate.— $C_{11}H_7NO_3 \cdot H_2SO_4 + 2H_2O$ forms thin, flat, shining prisms, up to 2 cm. in length. It is readily soluble in hot water, with difficulty in cold water or alcohol. An aqueous solution (1:300) yields the following reactions:—Potassium mercuric iodide, white amorphous precipitate, which soon becomes crystalline; iodine in potassium iodide, precipitate of fine steel-blue needles; potassium bismuth iodide, amorphous scarlet precipitate. Crystalline precipitates are also furnished by picric acid, $HgCl_2$, $AuCl_3$, and $PtCl_4$. By the latter, however, only from fairly strong solutions of the alkaloid.

Anhalonidine.— $C_{16}H_{12}NO(OCH_3)_2$. The crude alkaloid, obtained as described, is contaminated with mezcaline, from which it is best separated, although the process is somewhat wasteful, by fractional crystallisation of the platinum double salts. The mezcaline compound, being decidedly the more soluble of the two, remains in solution. Anhalonidine crystallises in small yellow needles, m. pt. 160° C., and is readily soluble in water and the usual organic solvents. Its sulphate and hydrochloride form felted needles and

colourless plates respectively, and are both easily soluble in water. An aqueous solution of the hydrochloride is dextro-rotatory.

Reactions (solution, 1:300). Potassium mercuric iodide, pale yellow amorphous precipitate, soon changing to aggregates of small prisms; iodine in potassium iodide, precipitate of thin light brown needles; gold chloride, long thin yellow plates; potassium bismuth iodide, phospho-molybdic and phospho-tungstic acids, red and yellow amorphous precipitates respectively.

Anhalonine.— $C_{12}H_{13}NO_3$. Lewin's account of this alkaloid is in general confirmed, although the author finds its melting point somewhat higher— $85.5^\circ C.$ as against $77.5^\circ C.$ The base is much less soluble in water than of the preceding, and is at once precipitated in snow-white needles on addition of ammonia to solutions of its salts. The hydrochloride forms long colourless prisms, readily soluble in hot water, with difficulty soluble in cold water or alcohol. The solution is levo-rotatory.

Reactions (with solution 1:300). $HgCl_2$, long white needles; potassium mercuric iodide, white precipitate, rapidly becoming crystalline; potassium bismuth iodide, amorphous vermillion precipitate.

Lophophorine.— $C_{13}H_{17}NO_3$. The base separates in oily drops when potash, &c. is added to a solution of the hydrochloride. It is readily soluble in organic solvents, but does not crystallise. The hydrochloride is soluble in water and alcohol, and crystallises from the latter in microscopic needles.

Reactions (with solution 1:300). $AsCl_3$, light brown amorphous precipitate, which, after a time, is partially converted into yellow leaflets; picric acid, yellow spherules of fine needles; $HgCl_2$, warty masses of fine white needles; iodine, potassium mercuric iodide, phospho-tungstic, and phospho-molybdic acids produce coloured precipitates. All the preceding bases (including pellotine) yield, when moistened with strong sulphuric acid, a citron yellow coloration, changing to violet on the application of heat. With nitrosulphuric acid a deep violet tint, changing to brown, is obtained.

Physiologically, lophophorine is by far the most active of the above alkaloids. 0.27 mgrm. produced strong convulsions in a frog, whilst 1.1 mgrm. proved a fatal dose.

—H. T. P.

Raphanol, New Compound obtained from the Root of Raphanus Niger or Black Radish (Crucifera) and from some other Plants of the same Family. The Essence of Raphanus Niger. H. Moreigne. Bull. Soc. Chim. 1896, 797—806.

By distilling the root of raphanus niger with steam, there passes over together with the essence a small quantity of a white solid which is separated by filtration through cotton-wool and extraction with ether. The yield of the new product is very small, only 4—5 grms. being obtained from 200 kilos. of the root. The yield of oil is about the same. The new substance crystallises in thin mother-of-pearl plates, and when pure it is odourless and melts at $62^\circ C.$ It is insoluble in water, soluble in ether, chloroform, benzene, and petroleum ether, and somewhat soluble in absolute alcohol, less so in 90 per cent. alcohol. In alkalis and acids at the ordinary temperature, it is insoluble, but it dissolves in boiling acetic acid. Analysis, &c. indicate the formula $C_{20}H_{32}O_4$. The author considers that the product is present in the root and is not formed during distillation. He has obtained the same substance from other crucifers, such as red radish, turnip, ordinary radish, cress, cochlcaria officinalis, &c. The oil obtained from raphanus niger, together with the raphanol, is reddish yellow, has an acid taste and peculiar smell, different from that of the oil of mustard or horse-radish, and hence it does not contain potassium myronate. The oil contains sulphur but no nitrogen, and distils at about $300^\circ C.$ with decomposition, the distillate smelling of cod-liver oil. Unlike mustard oil, it does not combine with ammonia in an alcoholic solution, which under these conditions forms thioisamine.

—T. A. L.

Quinine, The Chlorhydro-Sulphate of. M. Georges. J. Pharm. Chim. 1896, VI. 3, 589.

This salt, under the microscope, appears as a mixture of some fine crystalline needles with a considerable quantity of small amorphous granules. The aqueous solution of a commercial sample, which, of those examined, most nearly corresponded in composition with the formula—

was evaporated *in vacuo* and submitted to fractional crystallisation. Analyses of the products obtained satisfied the author that the so-called quinine chlorhydro-sulphate can hardly be a distinct chemical compound; that the commercial article contains varying quantities of basic salt and thus should not replace the neutral hydrochloride for therapeutical purposes.—A. C. W.

Sugar Bush. O. Hesse. Annalen 290, 317—321.

This shrub, *Protea mellifera*, grows abundantly in South Africa and blossoms in January and February. It owes its name to the sweet sap which can be expressed from its flowers. The extract, after mixing with ginger is evaporated to the consistency of molasses and used as a preserve or in cases of laryngeal catarrh. The leaves, twigs, or flowers give, on extraction with ether, a crystalline residue intermixed with gum, containing a phenol and an acid soluble in water. The former is nothing else than hydroquinone and is contained to the extent of about 2—5 per cent. in the plant. The acid, which can be isolated best by means of the lead salt and separation with sulphuric acid, forms white granular crystals melting at $187^\circ C.$ with evolution of carbonic acid. From its analysis, formula of its lead salt, and its reactions with various reagents, the author concludes that the substance which he calls proteic acid is the next higher homologue to homoproteoatechnic acid, and is, in fact, ethylproteoatechnic acid, having the formula—

—T. A. L.

Pyranine. A. Piutti. J. Pharm. Chim. 16, 298—299.

PYRANTIN, *p*-ethoxyphenylsuccinimide, is obtained by melting together either the hydrochloride of *p*-amidophenetol and succinic acid, or phenacetin and succinic acid, and extracting the resulting substance with boiling alcohol, from which the pyranine crystallises out on cooling in colourless prismatic needles, which melt at $155^\circ C.$ It is insoluble in ether, very slightly soluble in cold water, but more so in hot. It splits up into succinic acid and *p*-phenetidine when treated with hydrochloric acid or when heated with potassium acid sulphate. Chromic acid gives a ruby-red coloration with a solution of pyranine in hydrochloric acid, which has been diluted with water. If pyranine be melted with potassium hydrate, the product dissolved in water and a little calcium hypochlorite added, a red coloration is obtained. Ammonia and chlorine water give a yellow colour with an aqueous solution of pyranine. When treated with alkalis, salts of *p*-ethoxyphenylsuccinamic acid are formed.

Both pyranin and this sodium salt possess marked antipyretic action.—J. G. W.

Alcohol and its Derivatives; Report for the Year 1895. M. Klar. Die Chem. Ind. 1896, 19, 159.

Chloroform.—Commercial chloroform, as at present produced, is sufficiently pure for use as an anæsthetic. It has been recently prepared in an especially pure condition, it is said, by an electrolytic method. A 20 per cent. solution of sodium chloride is heated to boiling in an enamelled vessel provided with two leaden electrodes, and a current of acetone led through it simultaneously with the passage of an electric current. The acetone is chlorinated by the chlorine evolved during electrolysis, and the chlorinated product converted into chloroform by the caustic soda set free; 190 kilos. of acetone yield 190 kilos. of chemically pure chloroform.

Chloroform is also prepared from carbon tetrachloride, which is made by saturating carbon bisulphide with dry chlorine. The SCl_2 formed in this operation is converted into S_2Cl_2 by the addition of half as much sulphur as the

carbon bisulphide used, and the carbon tetrachloride (boiling below 130°) is separated by fractional distillation, and purified by distillation with steam. 100 kilos. of carbon bisulphide yield 170 kilos. of CCl_4 and 150 kilos. of SCL_2 . The carbon tetrachloride is reduced to chloroform by the action of zinc and hydrochloric acid—

L. Allain finds that the addition of a little (0.1 per cent.) sulphur to chloroform prevents its decomposition in a very complete way.

Chloral Hydrate.—According to E. Schaer, chloral alcoholate, as such, is very slightly soluble in water. It dissolves slowly, being converted into the hydrate. Similarly chloral hydrate is converted into alcoholate when dissolved in alcohol. Douglas states that a moderately concentrated solution of potassium carbonate is a good antidote for chloral poisoning, provided the poison has not reached the blood.

Bromoform.—G. Vulpius finds that pure bromoform has the specific gravity 2.904 at 15°; it is more unstable than chloroform, and for pharmaceutical purposes it is therefore advisable to mix it with 1 per cent. of alcohol; the specific gravity of this mixture is 2.885 at 15°; it boils at 148° and solidifies at 7°.

Iodoform.—A substance recently placed on the market, called "iodoformin," is said to possess no ill odour. According to E. Konteschweller, it is a compound of hexamethylene tetramine (Urotropin) and iodoform. It forms compounds with metals, that with mercury, being already an article of commerce. The smell of iodoform may conveniently be removed from hands, &c., by moistening them with an alcoholic solution of Urotropin.—T. E.

Terpene Alcohols, Extraction of, from Essential Oils. A. Haller. *Comptes rend.* 1896, 122, 865—869.

THE percentage of the terpene alcohol contained in the oil is first determined, after which the part of it which is present in the form of ester is hydrolysed by means of alcoholic potash. The product, after washing and drying over anhydrous sodium sulphate, is treated by one of the two following processes:—

(1.) The essence, alone or diluted with a hydrocarbon, is heated with the quantity of succinic or phthalic anhydride required to form an acid ester. After cooling and filtering, the liquid is extracted with a concentrated solution of sodium carbonate. The aqueous solution is then extracted with ether, and heated with excess of caustic soda on the water-bath, or acidified. The product in either case is completely hydrolysed by alcoholic potash, washed, and rectified.

(2.) The essence is dissolved in ether or benzene, and treated with a quantity of sodium equivalent to the alcohol which it contains, after which succinic or phthalic anhydride is added; the sodium salt of the acid ester is then extracted with water and treated in the same way as in (1).

The second method is applicable to essences containing alcohols which are dehydrated by acids; aldehyde may be removed by bisulphite. Geranium oil from Bourbon, containing 67.2—68.8 per cent. of geraniol, yielded 79 per cent. of the total quantity by the first, and 25—50 per cent. by the second method. An African geranium oil yielded 50.5 per cent. of its geraniol by the first, and 61.1 to 77.8 per cent. by the second method. American essence of mint (containing 52.5 per cent. of menthol) yielded 84 per cent. of the menthol by method (1). Citronella oil yielded 51 per cent. of the alcohol contained in it by method (2), and oil of spike also yielded 50 per cent., chiefly linalool and borneol.—T. E.

Glycerophosphates, Contribution to the Study of. G. Delage. *les Nouveaux Remèdes*, 1896, 12, 217.

GLYCEROPHOSPHATES may be prepared readily and in a state of purity by a process of which the following is a typical example. One part of phosphoric acid of 60 per cent. strength is mixed with $1\frac{1}{2}$ parts of glycerin, and heated until acrolein is evolved; this substance is given off at about 170°—190° C. The syrupy liquid product is allowed to cool, and is poured into a liquid consisting of

precipitated chalk, suspended in five times its weight of water. After long standing, the precipitate is filtered off, and the filtrate precipitated by the addition of half its volume of 90 per cent. alcohol. By this means a flocculent precipitate of calcium glycerylphosphate is thrown down, whilst another salt of similar or identical composition remains in solution and can be obtained in a gelatinous state by warming the solution. The precipitate is dissolved in water and reprecipitated by alcohol, and dried at the lowest possible temperature over sulphuric acid. A white powder, showing a crystalline structure when examined under the microscope, is ultimately obtained. It is soluble in 20 parts of water, and its solubility is greatly influenced by fluctuating conditions. The author has prepared various other glyceryl phosphates in a similar manner. Those of magnesium, lithium and strontium were obtained in the dry state; those of potassium and sodium only in solution. The ferric salt is, on drying, a white powder, but after a time becomes vitreous and yellowish. All the salts may be dialysed, a property favourable to their therapeutical use; they are fairly stable when dry, but are easily decomposed in solution.—B. B.

Bismuth Bichloride. V. Thomas. *Bull. Soc. Chim.* 1896, 758—760.

OF the two series of halogen salts of bismuth known, one corresponds to the general formula BiR_3 , whilst the other has the formula BiR_2 , in the case of the chloride, the sub-bromide and iodide according better with the formula Bi_2R_3 . The action of water, air, and nitrogen peroxide on the halogen compounds of bismuth BiR_3 takes place in a simple manner, and the author has investigated the action of these reagents on the bichloride. Bismuth bichloride is prepared by careful treatment of bismuth with chlorine. It forms a black crystalline mass which does not melt at 300° C. When finely powdered and washed with water until the latter is no longer acid to litmus paper, a powder is obtained which consists of a mixture of bismuth and its oxychloride, the reaction taking place according to the following equation: $3\text{BiCl}_3 + n\text{H}_2\text{O} \approx \text{Bi} + 2\text{BiOCl} + 4\text{HCl} + (n-2)\text{H}_2\text{O}$. By heating bismuth bichloride to about its melting point, the residue consists of bismuth oxychloride, if purified by treatment with dilute nitric acid. Probably the reaction takes place in two stages, bismuth trichloride and bismuth being formed first.—T. A. L.

Vanillin, Methods of Preparation of. J. Altschul. *Pharm. Central H.* 1895, 16, 721.

THE author classifies the various methods for the preparation of vanillin as follows:—

- (1.) By oxidation of the aliphatic side chains in—
 - (a.) Coniferin, Glucovanillin, Olivil, Acetomovanillilic acid, Acetofervulic acid;
 - (b.) Eugenol, Iso-eugenol, Acetengenol, Engenol acetic acid, Acetiso-eugenol, Benzyliso-eugenol, Methyleneiso-eugenol, Iso-eugenolphenylacetic acid, Iso-eugenolitoic acid.
- (2.) From *p*-nitro-*m*-methoxybenzaldehyde prepared from toluene (as *p*-nitro-*m*-chlorotoluene), cinnamic acid (as *m*-methoxycinnamic ester), benzaldehyde (as *m*-amidobenzaldehyde).
- (3.) From the bimetallic salts, the monoacetyl compound, the benzyl compound, and the sulphobenzene compound of protocatechuic aldehyde by the introduction of a methyl group into this latter.
 - (1.) From guaiacol—
 - (a.) By the introduction of an aldehyde group by the action of chloroform and caustic potash;
 - (b.) By the conversion into guaiacol carboxylic acid, the introduction of the aldehyde group and separation of CO_2 ;
 - (c.) By conversion into guaiacol dicarboxylic acid, treatment with chloroform and alkali, and removal of the orthocarboxyl group.—J. T. C.

PATENT.

Vanillin, Improvements in the Manufacture of. O. Pren, Vienna, Austria. Eng. Pat. 7692, April 11, 1896.

EUGENOL or iso-eugenol is converted into an acetyl derivative, which is then oxidised by chromyl chloride, CrO_2Cl_2 , and the resulting vanillie ether on saponification gives a good yield of vanillin. One molecular proportion of acetyl-eugenol or acetyl-iso-eugenol is dissolved in five times its volume of carbon bisulphide or chloroform. To this is then carefully added a solution containing two molecular proportions of chromyl chloride, also diluted with five times its bulk of the same solvent, the temperature being kept below 40°C . After standing over night the mixture is filtered and the chocolate-brown precipitate obtained, may be worked up by various methods, the following being a typical example:—The precipitate is dried at about 50°C . to drive off the solvent, and is then stirred into 6–10 times its weight of water, when acetyl-vanillin separates as a resinous mass. On warming this latter with a small excess of sodium hydrate, on the water-bath, saponification takes place, and after cooling and acidification with dilute sulphuric acid, the vanillin may be extracted with ether, and separated from the ethereal solution by means of an alkaline bisulphite, this compound being finally decomposed with dilute sulphuric acid. The crude vanillin is then purified.

XXI.—PHOTOGRAPHY.

Laccase, its Oxidising Power. G. Bertrand. Bull. Soc. Chim. 1896, 791–793.

See under XXIII., page 561.

PATENT.

Photographic Prints, Improvements in Chemical Compositions to be used for Preparing the Surface of Suitable Material for. P. E. Schoenfelder and E. Kehle, Newark, N.J., U.S.A. Eng. Pat. 6651, March 26, 1896.

A METHOD is claimed for the preparation of a "self-toning" photographic film, this film requiring only to be fixed after the exposure. $1\frac{1}{2}$ oz. of a collodion, made by dissolving 300 grains of pyroxyline in 1 lb. each of absolute alcohol and ether, are mixed with 10 drops of a solution of 15 grains of the chloride of gold, platinum, iridium, rhodium, osmium, or palladium dissolved in $\frac{1}{2}$ oz. of 40 per cent. alcohol. Three grains of an organic acid (e.g. citric acid), 15 of silver nitrate, and $1\frac{1}{2}$ of the chloride of barium, strontium, or zirconium, each dissolved separately in a small quantity of spirit, and 2 drops of glycerin or castor oil are then added in succession to complete the emulsion. The surface must be thoroughly dried before use. After printing, the paper, &c. is fixed in 1:15 thiosulphate. A similar emulsion can be made in gelatin, the other ingredients being then dissolved in water.—F. H. L.

XXII.—EXPLOSIVES, MATCHES, Etc.

Explosives, The Annual Report (Twentieth) of Her Majesty's Inspectors of, for 1895.

THIS being the 20th year since the Explosives Act came into force, the inspectors in their annual report, recently issued, give a short review of the principal changes which have occurred during this period in addition to the work of the past year.

The growth of the trade in explosives during the 20 years, has been very great. In 1875 there were only 55 factories, now there are 134. Dynamite was then practically the

only nitroglycerin compound for blasting purposes in the market, and all made in one factory, whereas now it has been largely replaced by gelignite, gelatin-dynamite, &c., 12 varieties of which compounds are made in nine factories.

Smokeless powders had not been introduced then, now there are 14 factories licensed for their manufacture. Four new factories were licensed last year.

The following have been added to the list of authorised explosives:—Dahmenite A, Electronite (Nos. 1 and 2), Emerald Powder, Faversham Powder, Pigou's Military Smokeless Powder, Pigou's Sporting Smokeless Powder, Roburite No. 3, Rosslyn Smokeless Powder No. 1, Rosslyn Blasting, Low Tension Electric Fuses (No. 5 Definition), Low Tension Electric Detonator Fuses.

It has been decided that gunpowder cartridges enclosing sealed tubes containing liquid ammonia may be treated as gunpowder blasting cartridges pure and simple (not containing their own means of ignition). It is added, however, that the point is not free from doubt and the "decision must be regarded as susceptible of modification by light of experience or in consequence of a decision of a court of law."

In regard to the mixing of dry cap composition, all the manufacturers who prepare it in this state have adopted the "jelly bag" system, and it has been found to work most efficiently and safely.

The amount of foreign nitroglycerin compounds imported was 880,070 lb., compared with 539,802 lb. in 1894, and the amount of dynamite has risen from 23,000 lb. to 56,000 lb. The number of detonators imported during the year was 6,981,000, against 9,765,400 in 1894. A large percentage remains in foreign hands, but now there are six factories for the manufacture of detonators in this country.

Dr. Dupré states in his report, which is given *in extenso*, that for the first time since the chemical examinations have been undertaken there have been no rejections among explosives proper; although there is still room for improvement, the defects noticed were not of a sufficiently grave character to demand the condemnation of any explosive.

Some samples of coloured stars had to be rejected on account of their containing both chlorate and sulphur in their composition contrary to Order in Council, No. 15, which came into force on Jan. 1, 1895. "In relation to this," Dr. Dupré says, "I should like to draw the attention of firework makers to the practice of using, sometimes a not inconsiderable proportion, of gunpowder containing sulphur, as a priming for stars. This is not, I believe, against the above-mentioned Order as at present drawn, but as, at least, one accident has been directly traced to the mere contact of a chlorate with a sulphur mixture it might be well, if possible, to replace the ordinary gunpowder containing sulphur by a powder free from such."

A sample of gun-cotton about 25 years old, and contained in a tin canister, perforated in several places by corrosion, the gun-cotton in contact with the metal being stained dark reddish-brown, was examined and gave the following results:—

Nitrocellulose, insoluble	95.46	Heat test one hour.
" soluble	3.50	Nitrogen 13.2 per cent.
Mineral matter	1.61	
	100.00	

showing that the gun-cotton was of remarkably good quality although manufactured so long ago.

The following important alterations in the tests applied to explosives have been adopted.

The heat test for gun-cotton and non-gelatinised gun-cotton preparations has been made more stringent by raising the temperature to be employed from 150° to 170°F ., leaving the time, viz., 10 minutes, unaltered.

The temperature for the heat test to be applied to all horny or semi-horny explosives consisting mainly of gelatinised gun-cotton (such as Walsrode powder) and gun-cotton mixed with nitroglycerin (such as cordite and ballistite), has been raised to 180°F .

The number of accidents by fire or explosion known to the Department during the year was 152, causing 40 deaths

and injuring 167 persons, but four-fifths of the accidents causing death or personal injury occurred in the use of explosives and under miscellaneous conditions to which the controlling provisions of the Act do not apply.

A short account is given of each of the principal explosions at home and abroad and also of outrages and attempts.

Experiments were carried out with a view to ascertaining—

(1.) If the magazine clothing supplied by the Government (*viz.*, lasting cloth jackets, and stout woollen cloth army trousers) possessed the necessary quality of unflammability when cordite (or other nitro-compound) was present; and (2) the relative value for this purpose of different fabrics.

The results appear to justify the following conclusions:—

1. That lasting cloth, treated or untreated, is not unflammable.

2. That chemical treatment has very little effect in diminishing the inflammability of woollen fabrics.

3. That chemical treatment cannot be depended on for rendering thin cotton fabrics unflammable.

4. That the protective value of any material, treated or untreated, is largely affected by its thickness.

5. That stout Osnaburgh, chemically treated, is unflammable under all reasonable conditions, and serviceable.

6. That stout woollen cloth (such as is used for army trousers, whether with or without treatment, is unflammable, under all reasonable conditions, and serviceable."

The "chemical treatment" referred to is either treatment with a solution of tungstate and phosphate of soda or a solution of tungstate of soda alone.

Further experiments were made with other materials and of all those tried the most satisfactory in every respect is "white duck" as supplied to the Army Clothing Department when treated with a solution proposed by the Lancashire Explosives Co. The solution is prepared as follows:—

Ammonium sulphate, 8 parts.	Dissolve, then add starch,
Ammonium carbonate, 2½ "	stir well, and boil.
Boric acid, 3 "	The fabric should be dry
Borax, 1½ "	before steeping in this
Water, 200 "	solution.

—W. M.

Smokeless Powder, The Pyrocollodion, of Mendelëff.
P. Kouindjy. Bull. de la Soc. d'Encouragement pour l'Industrie Nationale, 94, 1100—1113.

EXPERIMENTS have been carried out during the years 1890—1895 by M. Mendelëff on behalf of the Russian Government with the object of producing an improved smokeless powder, and the results of these experiments are described in a report recently published in the *Journal de la Marine Russe*.

The most important substances used hitherto in the manufacture of smokeless powders, are the two chief products of the action of nitric acid on cellulose, *viz.*, pyroxylin and collodion cotton. In the so-called "pyroxylin" powders, a mixture of these two substances is employed, in which pyroxylin is the explosive and collodion cotton the gelatinising factor. Other smokeless powders, *e.g.*, cordite and ballistite, are made from collodion cotton and nitro-glycerin. Collodion cotton, as usually prepared, contains 12.5 per cent. of nitrogen, and pyroxylin 12—14 per cent. Eder has shown that by precipitating certain varieties of nitro-cellulose from their solutions in suitable solvents, a definite compound pentanitro-cellulose can be obtained containing 12.7 per cent. of nitrogen. Mendelëff has succeeded in preparing, by the action of nitric and sulphuric acid upon cellulose, a new nitro-derivative intermediate between pyroxylin and collodion cotton and therefore named by him "pyrocollodion." This substance contains 12.5 per cent. of nitrogen and is not identical with Eder's pentanitro-cellulose, for whilst the latter has the formula $C_{12}H_{14}(NO_2)_5O_{10}$, pyrocollodion is $C_{30}H_{38}(NO_2)_{12}O_{25}$.

In a series of practical trials carried out with small arms and cannon of every description, and described in detail in the report, the pyrocollodion powder was compared with other smokeless and non-smokeless powders. The

substance is easily gelatinised and can be made into the form of laminae consisting of a homogeneous translucent mass similar to glue or celluloid, it is very stable, and on explosion leaves no residue whatever. Other advantages of the new powder are said to be as follows:—

(1.) It is of uniform composition, and by its use a uniform initial velocity of the projectile is obtained.

(2.) This velocity may be varied at will by varying the size of the grains of powder; with large grains it is possible to obtain a very high velocity without injury to the cannon.

(3.) By increasing the size of the grains the powder may be made to burn very slowly; this is indispensable for cannon of large calibre.

(4.) The velocity is greater than is produced by other powders.

Pyrocollodion powder was found to give satisfactory results in every case in which it was tried, both as regards velocity and range of the projectile, and it appears to be equally suitable for naval and military purposes, for large and small cannon, for shells, and for small-arms.—R. B. B.

PATENT.

Fuses or Match-cords, Improved Manufacture of. M. Wagner, Berlin. Eng. Pat. 7711, April 11, 1896.

THE aim of this patent is to produce a fuse that will burn without flame, and at the same time to increase the certainty of ignition. A suitable fibre, either nitrated or not, is impregnated with a drying oil and a salt containing much water of crystallisation, *e.g.*, magnesium sulphate, sodium carbonate, alum, &c., or with albuminous bodies or glue. To attain the second object, diazo compounds of the benzene or naphthalene series are made use of, more especially diazobenzene sulphonic acid and its chromium and bromine derivatives. The whole fuse may be waterproofed and rendered still safer in the presence of fireproof by the employment of chromium glue, in which case it must be exposed to light to render the coating thoroughly insoluble.

—F. H. L.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS, ETC.

Photometry, A Suggested Remedy for a Source of Error in Official. L. T. Wright. J. Gas-Lighting, 67, 1896, 1213—1214.

THE author points out that in the instruction of the London Gas Referees the operator is told to burn the gas at 5 ft. per hour and then multiply the photometric reading obtained by the factor of correction due to temperature and pressure. He maintains, however, that the number so obtained is not necessarily the same as, and may often vary by 3—4 per cent. from, the result obtained by actually burning 5 ft. normal, this latter being evidently intended by the Act of Parliament. The error in the present method is due to the difference of efficiency of the argand burner when consuming different quantities of gas.

The author considers that more constant and reliable results would be obtained if the volume of gas at the conditions of temperature and pressure of the test which would equal 5 cb. ft. normal, were first calculated and then consumption regulated to that rate. More reliable results than at present would also be obtained if the gas were always consumed at a rate sufficient for the flame to just fill the chimney, and then correction for quantity made; or if, with any rate, the admission of air to the argand were regulated, as by the latter means the maximum efficiency of the gas may also be obtained.—L. T. T.

Acoustic Analysis of a Mixture of Air and another Gas (or of two Gases of different Densities). E. Hardy. Bull. de la Soc. d'Encouragement, May 1896, [5], 653—665.

WHEN air of the same composition and temperature is blown into two identical pipes, like organ-pipes, they produce the same note; but if one of the two pipes be fed with air containing even a small proportion of a gas of different density it

gets out of tune and beats are produced. Other things being equal, the number of beats produced in a given time is proportional to the amount of the foreign gas in the mixture. This is the principle upon which the author's method of acoustic analysis is based.

One of the two pipes may be enclosed in an envelope containing pure air which never mixes with the atmosphere outside; this pure air goes from the pipe back into the blower and is again forced into the pipe. The second pipe is fed with air from the surrounding atmosphere. If this consists of pure air the two pipes will be in unison. But if the apparatus be placed in a mine containing marsh-gas, they will no longer give the same note. The number of beats in a given time will, under proper conditions, be proportional to the amount of marsh-gas present. Obviously the removal of any carbonic acid is one of the requisite conditions; small variations in the amount of nitrogen present do not appreciably affect the result. The gases with which the two tubes are fed must be at the same temperature and in the same hygrometric state (e.g., both saturated with water-vapour).

The method can be employed for determining acoustically the amount of carbonic acid contained in furnace-gases. With organ-pipes giving 128 (double) vibrations per second, each hundredth part of carbonic acid in the furnace-gas produces about three beats in 10 seconds.—D. E. J.

INORGANIC CHEMISTRY.—QUALITATIVE.

Carbon Dioxide. Liquid; Methods for Experimental Examination of. B. Schwalbe. Zeits. phys. u. chem. Unterr. 1896, 9, 1.

DIRECTIONS are given as to the best method of obtaining samples from the cylinders. Solid carbon dioxide sprinkled on ignited petroleum extinguishes the flame. The but slight chemical activity of the snow may be demonstrated by adding concentrated ammonia, or an ammoniacal solution of barium chloride. That only a trifling sensation of cold is felt on touching solid carbon dioxide is accounted for by Leidenfrost's phenomenon, which may be illustrated by sprinkling the snow on water, when it is buoyed up by adhering bubbles of gas. To demonstrate the tension of compressed carbon dioxide an experiment is described in which a column of mercury is forced up by the expanding gas. By placing the solid substance in a flask, fitted with a cork through which passes a tube, and half filled with water, a small fountain is produced by the expansion.

Considerable friction occurs when the escaping liquid carbonic acid comes in contact with the wooden walls of the outlet-opening. When a cloth bag is used, friction of solid carbonic acid against wood and cloth takes place, and electric sparks are often observed during the preparation of solid carbonic acid. It may be demonstrated thus that the solid carbonic acid is negatively charged, whilst the cloth is positively charged with electricity.—C. A. M.

INORGANIC CHEMISTRY.—QUANTITATIVE.

Chlorides, Hypochlorites, and Chlorates, Volumetric Analysis of Mixtures of. A. Carnot. Bull. Soc. Chim. 1896, 15, 393—397.

THE hypochlorous, chloric, and hydrochloric acids are successively determined in the same portion of the mixture.

The hypochlorous acid is estimated in the usual manner by titration with sodium arsenite.

The chloric acid is then estimated by means of ferrous ammonium sulphate. To this end, an excess of the latter salt (at least 20 times the weight of the chloric acid present) is added, the solution is heated almost to boiling, and 5 c.c. of sulphuric acid, diluted with 15 c.c. of water, are gradually added. Then the flask, which contains the solution, is closed, and its contents, when cold are titrated with potassium permanganate.

Lastly, the chlorine, now wholly present in the form of hydrochloric acid, is estimated by titration with silver nitrate. This is added in excess, and the excess is determined by means of ammonium thiocyanate, the end-point

of the reaction being indicated by the red coloration produced by the interaction of this salt with the ferric salts in the solution.—E. B.

Chlorides, Chlorates, and Perchlorates, Analysis of Mixtures of. A. Carnot. Bull. Soc. Chim. 1896, 15, 397—399.

THE hydrochloric and chloric acids are estimated in either one or two portions of the sample.

In the former case the amount of hydrochloric acid present is first ascertained by titration of the neutral solution with silver nitrate, in the presence of sodium or potassium arsenate, instead of potassium chromate, for the definition of the end-point, as the last-named salt interferes with the succeeding estimation of the chloric acid.

The determination of the chloric acid is accomplished with ferrous ammonium sulphate, as described above (see the preceding abstract).

To estimate the perchloric acid, another portion of the mixture (sodium, potassium, or calcium salts) is taken, and mixed with 4—5 parts of pure quartz sand. The mixture is then placed in a platinum crucible, covered with a layer of sand 1—2 cm. deep, and heated for 20—30 minutes, so that the bottom of the crucible attains a red heat. The chloride thus formed, along with that originally present, is then volumetrically estimated.—E. B.

Portland Cement (Raw), Estimation of Lime in.

F. Kluge. Chem. Zeit. 20, 372.

A rapid and sufficiently accurate volumetric method for technical purposes consists in calcining 2 grms. of the raw material under examination (powdered so fine that 85 per cent. will pass through a 5,000 mesh sieve), in a smooth platinum crucible for 10 minutes in the full flame of a Bachelin blowpipe. After cooling for 5 minutes and weighing, the mass is emptied into a beaker containing 50 c.c. of hot distilled water, and is boiled therein for 1 minute, 40 c.c. of sulphuric acid (of $\frac{2}{3}$ normal strength) being thereupon run in and the boiling continued for a minute longer. After washing the crucible thoroughly with 50 c.c. of distilled water at room temperature, the titration is effected by means of potassium hydroxide solution (also of $\frac{2}{3}$ normal strength) with 20 drops of phenolphthalein (0.5 per cent. solution) as indicator. The volume of acid consumed in the primary reaction, calculated to the weight of calcined substance, gives a co-efficient for determining the lime, varying with different raw materials on account of the different proportions of alkalis in the total alkaline matter, but constant for each. The co-efficient will in each case have to be established by previous experiments.

—C. S.

Iron and Steel Analysis, Introduction of Standard Methods of. H. J. von Jon-torff. Iron and Steel Inst., Spring Meeting, 1896. The Ironmonger, 269—279.

AFTER instancing some gross discrepancies in the analysis of iron and steel in various and even in the same laboratories, and mentioning the work done and the results published by the various commissions of the world, formed to endeavour to obtain standard methods of analysis, the author turns to the problem itself and says it is evident that its solution must be preceded by an accurate knowledge of the causes that bring about the present differences in analytical results. These he classifies under eight headings, each of which he considers in full detail, viz.:—(1) Gross errors in the analysis; (2) Impure reagents; (3) Errors due to the apparatus, &c.; (4) Errors due to the operations; (5) Errors due to the analytical methods; (6) Personal errors; (7) Errors due to differences in the calculation of the analyses caused by the values of the atomic weights on which they are based; and (8) Want of homogeneity of the sample.

In the course of section 8 the fundamental importance of obtaining a fair sample of the material is emphasised, and in speaking of the irregular distribution of the elements in iron and steel the following two proposals are submitted:—(a) That it is best entirely to exclude average samples of metals; it is better to examine a number of separate samples and to calculate the average from these results;

and (b) in the case of grey or mottled pig-iron the whole of the quantity broken down should be used when determining the carbon.

In aiming at accurate analysis, however, it must be admitted that there are occasions when extreme accuracy is superfluous. The necessity of accuracy will depend on the purposes to which the analysis is to be applied, and these may be divided into, (1) Analyses which are intended for use in controlling the work in the factory; (2) Trade analyses; (3) Analyses which are to show the reason why the material under examination possesses certain properties, or whether it is suitable for certain definite purposes; and (4) Analyses connected with scientific investigation. Relative accuracy is adequate for controlling works operations where rapidity is the chief factor; and probably there is sufficient accuracy in analyses for trade purposes where they are controlled by specifications as to percentage limits, and to certain specified methods of analysis, but it is quite different in the cases of 3 and 4. In these something more even than mere chemical composition, however accurate, is becoming necessary, since the elements are now known to exist in so many different forms and combinations. Taking this into consideration, the field for investigation becomes so enormous that it will probably be found sufficient at present to settle three points, viz.: (1) investigations relating to the want of homogeneity in the samples, and to some decision as to the method of sampling; (2) examining the methods for the determination of the main constituents—that is, of carbon, silicon, manganese, sulphur, phosphorus, copper, and slag; and (3) the arrival at and agreement, if only temporary in character, as to the value of the atomic weights to be adopted for analytical calculations.—A. W.

Kermes. The Assay of. P. Lagüe. J. Pharm. Chim. 16, 341—343.

THE official assay of kermes consists of determinations of the yellow sulphide of antimony and of the iron salts, no notice being taken of the presence or amount of antimony oxide. For the estimation of this constituent the author treats with an aqueous solution of tartaric acid, preferably hot, and precipitates the antimony oxide, which enters into solution, by sulphuretted hydrogen. The antimony sulphide is dried at 100° C. and weighed. The sodium contained in the kermes as sulpho-antimoniate is also estimated. Kermes from various sources gives very different results when analysed in this way.—J. G. W.

Tin and Copper in Tin Dross. Estimation of. L. Rürup. Chem. Zeit. 20, 406.

To estimate the copper and tin in the dross from (molten) tinning baths in a rapid (2½ hours) and fairly accurate manner, 500 grms. of an average sample are fused in a Hessian crucible with cream of tartar, soda, and lime (Kerl's flux) in a blast furnace, until the slag runs easily, and, after cooling down, separating, and boring the regulus, treating 1 grm. of the borings with 25 c.c. of nitric acid (1·2 sp. gr.) and 10 c.c. of concentrated nitric acid, by warming on the air-bath. The precipitated metastannic acid is removed, washed, dried, incinerated, and weighed. The filtrate, containing copper and iron, is evaporated to dryness, taken up with 15 c.c. of 50 per cent. sulphuric acid, and the copper removed from the diluted solution by electrolysis. The results of six analyses of the same sample show that the greatest variation of the method, in the case of tin, was 0·18, and for copper 0·02 per cent., results which are more regular than are obtained by the wet method.—C. S.

Mercury. Electrolytic Estimation of. E. F. Smith and D. L. Wallace. J. Amer. Chem. Soc. 1896, 18, 169—170.

THE determination of mercury in cinabar by electrolysis of a cyanide solution, is a rather lengthy process, owing to the necessity of first dissolving the mineral in acid, the excess of which has afterwards to be removed. The authors have therefore tested the method first proposed by Smith, and which consists in electrolytically precipitating the mercury from its solution in an alkaline sulphide. They

recommend weighing the mineral in a platinum dish, dissolving it in 20—25 c.c. of a solution of sodium sulphide (sp. gr. 1·22), diluting to 125 c.c., and then electrolysis at 70° with a current of $N.D_{100}=0\cdot12$ ampère. The time allowed for the deposition of the mercury never exceeds three hours, and accurate results are obtained.—A. K. M.

ORGANIC CHEMISTRY.—QUALITATIVE.

Magenta and Acid Magenta, Distinction between. Schiff's Reaction. P. Cazenave. J. Pharm. Chim. 1896, 3, [11], 595.

ROSANILINE salts decolorised by sulphurous acid give a violet coloration with an alcoholic solution of form- or acetaldehyde. Under the same conditions acid magenta assumes the rose tint of the original colouring matter. The latter dyestuff does not dissolve in amyl alcohol in presence of alkali, as does rosaniline hydrochloride, and better resists oxidation by manganese dioxide and very dilute acids.—A. C. W.

Schiff's Reaction. G. Urbain. Bull. Soc. Chim. 1896, 15, 455—456.

WHEN aldehydes act upon rosaniline which has been decolorised with sulphurous acid, condensation takes place, with the production of aldehyde-rosaniline compounds, of violet or blue colours, which are unaffected by sulphurous acid.

The condensation of an aldehyde and rosaniline may be effected by means of hydrochloric acid, the aqueous solution, which is at first colourless, becoming in the course of 24 hours intensely blue-coloured.

V. Meyer has pointed out (Ber. 3, 2243) that Caro obtained a violet-red condensation compound from rosaniline and chloral, which he was unable to produce from chloral hydrate. This is not easily obtained, owing to the facility with which chloral in the presence of water becomes hydrated. It may, however, as the author finds, be readily formed in the following manner:—A few drops of Schiff's reagent, with a little ether, are placed in a test-tube, and a small quantity of chloral is added. On shaking the tube, the ether is coloured violet. Chloral hydrate under the same conditions does not give any coloration.—E. B.

Lard, Microscopic Detection of Beef Fat in. T. S. Gladding. J. Amer. Chem. Soc. 1896, 18, 189.

THE following method is recommended for the preparation of crystals of lard and beef stearin for microscopic examination:—Dissolve 5 c.c. of melted lard in a mixture of absolute alcohol (10 c.c.) and ether (5 c.c.); place a plug of cotton wool in the mouth of the flask and set aside in a cool place for about half an hour, when the stearin will crystallise out, leaving the olein in solution. Filter quickly and wash the crystals with a mixture of alcohol and ether (10:5). Allow the crystals to dry in the air, return them to the flask, dissolve in 25 c.c. of ether, insert cotton-wool plug, and place the flask in a slanting position in a large beaker of water. Keep this in a cool place over night; the ether evaporates very slowly and crystals of stearin are gradually deposited.—A. K. M.

Butter and Lard, Use of the Calorimeter in Detecting Adulterations of. E. A. de Schweinitz and J. A. Emery. J. Amer. Chem. Soc. 1896, 18, [2], 174—179.

THE determination of the heat of combustion of pure butters compared with that of mixtures of butter with oleomargarin is found to be of considerable value in detecting adulteration. Three samples of pure butter from different sources gave on combustion 9·327, 9·362, and 9·320 calories per grm. of butter, the samples being first prepared by washing, melting, filtering, and drying at 100°. A number of commercial oleomargarins have also been tested, and with these the number of calories per grm. vary between 9·574 and 9·95.

In the case of lard, if the number of calories comes out low, this would indicate that the article was either a compound or that it was from the caul, intestines, or head of the animals, and this point could be settled by means of

the iodine number and cotton-seed oil test. The determination of the heat of combustion of lard gave the following results, expressed in calories per gram. :—

Lard, leaf	95621
" caul fat	95573
" intestinal fat	95581
" heads	95563

—A. K. M.

Fluorine in Beer, Detection of Small Amounts of.
W. Windisch. *Wochenschr. f. Brau.* 1896, 419—450.

ONE litre of beer is freed from carbonic acid, filtered, and boiled. The hot beer is poured into a cylinder, and 100 c.c. of hot lime water are added; a voluminous precipitate is formed; this is collected and washed and introduced into a small platinum dish. The dish and its contents are then gradually heated to incandescence, and the contents, when cold, moistened with three drops of water and 1 c.c. of concentrated sulphuric acid. The dish is heated on the water-bath and covered with a watch glass which has been coated with wax, and a few scratches made on the wax coating; if fluorine compounds have been added to the beer, hydrofluoric acid will be liberated, and will etch the glass.—A. L. S.

Wheaten Flour, Method for Detecting Aniline Blue Colouring Matters in. C. Violette. *Bull. Soc. Chim.* 1896, 15, 156.

A SHEET of filter-paper is placed upon the surface of water, and a little of the sample to be examined is sprinkled over it. If the sample contain any coal-tar colouring matter, such as is employed for counteracting the faint yellow colour of flour, dark-coloured specks soon make their appearance on the paper. These rapidly increase in size, forming, after a little while, blue spots several mm. in diameter, with dark centres.—E. B.

Laccase: its Oxidising Power. [Discrimination of certain Photographic Developers.] G. Bertrand. *Bull. Soc. Chim.* 1896, 791—793.

IN continuing his researches on laccase (this Journal, 1895, 374 and 1074), the author has subjected a number of substances (alcohol, paraldehyde, glucose, urea, &c.) to the action of laccase in presence of oxygen, but finds that the oxidising action only takes place with aromatic compounds, and especially with those containing at least two OH or NH₂ groups situated in the ortho- or preferably in the para- position. Hence a certain relationship exists between this action and the photographic developing power of certain of these compounds. Thus, *p*-amidophenol, which is a good developer, is rapidly oxidised in presence of laccase and air; whilst *m*-amidophenol, which does not develop, is scarcely acted on. The same difference exists between *p*- and *m*-phenylene diamine. It would appear that the oxidisability of these polyphenols depends upon the facility with which they yield quinone, and it is to be remarked that whilst phloroglucinol [(OH)₃=1:3:5] is scarcely acted on, pyrogallol (1:2:3) rapidly absorbs oxygen; and the same is also true of protocatechuic acid [CO₂H:OH=1:3:4], gallic acid—

and more especially of hexaphenol, C₆(OH)₆. Thus also, this reaction serves to distinguish laccase from other soluble ferments.—T. A. L.

ORGANIC CHEMISTRY.—QUANTITATIVE.

Sugar, Estimation of, by the Copper Method. Kaiman. *Gesterr. Zeits. Zuckerind.* 1896, 25, 43.

THE cuprous oxide arising from the reduction of Fehling's solution by solutions of sugar, is filtered on to ignited asbestos contained in a glass tube, and washed with hot water. The asbestos plug is then removed by means of a glass rod, and placed in 50 c.c. of a solution consisting of 100 grms. of ferric sulphate, 100 c.c. of concentrated sulphuric acid, and 909 c.c. of water. The tube is rinsed out and the amount of reduced ferric salt titrated with ^N/₂₀ potassium permanganate solution, the titre of which is

calculated in terms of copper :—56 grms. iron = 63 grms. oxalic acid = 63.3 grms. copper. The whole operation takes about 15 minutes. (See also Neitzel, *Oesterr. Ungar. Zeits. Zuckerind.* 1893, 16.)—J. L. B.

Caffeine in Tea, Estimation of. A. Petit and P. Terrat. *Bull. Soc. Chim.* 1896, 811—815.

THE authors, considering current methods unsatisfactory, submit the following :—25 grms. of the powdered tea are mixed with 75 c.c. of boiling water and allowed to stand 15 minutes with occasional agitation. The mixture is then evaporated on the water-bath until the tea is only just moist, when the whole is extracted with chloroform, the extraction being continued until the residue left after distilling off the chloroform and taking up with boiling water gives, after filtering, neither a precipitate nor turbidity, with tannin solution. The chloroform is then evaporated, the residue dissolved in boiling water, filtered, and the solution evaporated on the water-bath. Generally the caffeine so obtained is sufficiently pure to be weighed directly, but if it be necessary to free it from chlorophyll it is dissolved in the cold in 15 c.c. of 10 per cent. sulphuric acid, filtered, the acid neutralised with ammonia and evaporated to dryness, the residue being extracted with chloroform, which is evaporated at a very low temperature. Almost equally satisfactory results are obtained by the use of 60 or 80 per cent. alcohol for extracting the dry tea, whilst the yield of caffeine is only very small if 98 per cent. alcohol be used. The compound or compounds of caffeine existing in the tea only decompose in presence of water, and recombine when the moist tea is dried. The same process can be employed for estimating the amount of caffeine in coffee, kola, maté, or guarana.—T. A. L.

Alcohol, Estimation of Essential Oils in, by Means of Common Salt. M. Kontcheroff. *Bull. de la Soc. d'Encouragement*, 1896, 571—589.

THIS method, which is similar in principle to that of Röse, consists in diluting the sample of alcohol to a strength of 60 per cent. by volume, adding exactly 1 per cent. by volume of amyl alcohol (to assist in the extraction of the oils), and shaking the mixture in a special apparatus with 3.5 vols. of saturated brine. The volume of the oily layer which rises to the surface, diminished by a constant due to the amyl alcohol added, is a function of the volume of essential oils contained in the sample, and, by reference to a

table empirically constructed by a method detailed in the paper, gives at once the percentage.

The apparatus consists of a conical vessel A, having a capacity of 150 c.c., with a long capillary neck, *a*, graduated in 0.005 c.c. divisions. This vessel is joined to the level tube, B, by a flexible connection, as shown in the figure. The vessel, A, is detached and inclined, whilst 20 c.c. of the sample of alcohol, prepared as stated above, is introduced through the neck, *a*; it is then connected to B, which contains the salt solution. On opening the clips, the requisite volume of salt solution flows into A. The salt solution and alcohol are then well shaken together for two minutes, allowed to stand 20 minutes for the separated oil to rise, and then, by admitting mercury through B, the clear oil is forced up into the capillary neck and measured.

As amylie alcohol is not a simple body, the author finds that the volume to be subtracted from the oily layer varies with different samples, and hence the curves and tables given in the paper must be modified by each operator according to the nature of the amylie alcohol which he employs. The essential oils are also very variable in composition, such bodies as isobutylie and propylie alcohols, ethers, aldehydes, &c. occasionally predominating. The author states that the influence of these bodies is inconsiderable, but he describes experiments which show that their presence may completely modify the results obtained. M. Bardsy, therefore, in a critical note preceding the abstract, considers that this method is not more accurate than that of Rösse, though likely to be useful in special cases, as it affords, for instance, an approximate and rapid method of comparing samples containing a large proportion of amylie alcohol.—L. A.

Fats, Butters, and Oils: Electrical Conductivity of. 1. Herlant. Bull. Assoc. Belge des Chimistes, 10, [2], 48—54.

It is proposed to take advantage of the difference in specific resistance to the passage of an electric current exhibited by solutions of fats saponified by an excess of potash, in comparison with a solution of normal alcoholic potash. To insure comparable results it is necessary to work with exact quantities of fat and potash, saponify constantly in the same manner, maintain a constant temperature, and always keep to the same strength of solution. Working with 10 grms. of purified fat (by extraction) and 45 c.c. of normal alcoholic potash, saponified by heating for half an hour on the water-bath under an inverted condenser, and making up the solution to 250 c.c. with distilled water, the author found the specific conductivity of three pure butters to approximate to 0.00650 at 18°C., whereas margarine ranged from 0.008221 to 0.008489, cotton-seed oil 0.008629, arachis oil about 0.00870, sesamé oil 0.008779, and olive oil 0.009927. The presence of sesamé or arachis oil in margarine gave the higher figures.

The specific conductivity decreases when the solutions are kept, especially in the case of butter, which fell off 0.009217 in six weeks.

The author considers that by the aid of a sufficiently large number of determinations it will be possible to set up an average conductivity for butter and for margarine, and thereby detect adulteration.—C. S.

Sulphur in Illuminating Gas and Coal, Determination of. C. E. Mabery. Amer. Chem. J. 18, 207—215.

For gas-testing, the combustions are made in a glass tube 45.5 cm. long, constricted at 30 cm. from the forward end. The jet, of hard glass tube, is connected with a gas-meter, a pinch cock and a wash-bottle containing a little water being interposed for the better regulation of the gas supply. The air current enters through another tube, which communicates with the outside of the laboratory, and the rate of flow is kept up by an exhaust of some kind. For the absorption of the products of combustion, a U-tube, 34 cm. high and 25 mm. internal diameter, partly filled with broken glass, is used, containing $\frac{1}{100}$ -normal caustic soda solution, this strength being found to retain the sulphuric acid perfectly. Titration is effected by $\frac{1}{100}$ -normal sulphuric acid, with methyl-orange as indicator. The results obtained do not

vary beyond the limits of error, the oxidation and absorption being complete, as was shown by the fact that the addition of hydrogen peroxide to the caustic soda solution effected no change in the results. The author is convinced, from numerous determinations made with asphalts, coal-tar, petroleum products, and gas, that the method leaves nothing to be desired on the score of simplicity and precision for organic bodies leaving no inorganic residue.

In examining coal, the combustion is performed in a tube of very hard glass (in length 10 cm. beyond and 25 cm. behind the constriction), the substance being inserted in a platinum boat. A rapid stream of air is allowed to enter at the constriction and a slower current (to carry the volatile matters forward and assist the combustion) from behind. The U-tube contains 30 c.c. of decinormal (or $\frac{1}{2}$ -normal) caustic soda, the titration being performed as in the examination of gas, but with correspondingly stronger acid. Some care is needed during the distillation of the volatile matter, which for 0.5 grm. of coal will take 20 minutes, a further 10 minutes being required for burning off the fixed carbon. For coke, a current of oxygen is preferable to air.

Suitably modified, it might, in the opinion of the author, be possible by this method, with an inert gas, to distil off the volatile matter and weigh the fixed carbon before completing the sulphur determination.—C. S.

Iron, The Colorimetric Estimation of Traces of [in Wines, &c.], by means of Potassium Sulphocyanide. A. Bornträger. Chem. Zeit. 1896, 398—399.

One hundred c.c. of the wine to be examined are evaporated and the residue completely reduced to ash. This is dissolved in water acidified with 5 c.c. of dilute hydrochloric acid (sp. gr. 1.1), and the solution made up to 100 c.c. To this is added one-tenth of its volume of a 10 per cent. solution of potassium sulphocyanide, and the colour of this is compared with that of a solution of ferric chloride (0.01 grm. Fe in 1 litre), to which the same proportion of potassium sulphocyanide solution has been added.

The ferric chloride solution is prepared by dissolving 0.1 grm. of piano-wire in dilute hydrochloric acid, oxidising with nitric acid, evaporating with excess of hydrochloric acid, dissolving in water with just sufficient hydrochloric acid to give a clear solution, and then, after the further addition of 100 c.c. of dilute hydrochloric acid, making up to 1 litre. For making the estimation, 10 c.c. of this solution are taken, 2 c.c. of dilute hydrochloric acid added, and the whole diluted to 100 c.c.

The author has found that the salts commonly present in wine-ash do not affect the accuracy of this method.

It may be added that the comparison of the colours of the solutions is conveniently effected by diluting the darker solution until the colours of the two become the same.

—A. L. S.

Malt, Estimation of Ready-formed Sugars of. G. H. Morris. J. Fed. Inst. Brewing, 1896, 2, 224—244.

The following experiments were carried out in order to find a method by which the true ready-formed sugars could be easily and directly determined for commercial purposes. In the first place, the author ascertained the time required to extract the whole of the ready-formed sugars without the products of diastatic action. For this purpose, ground malt was digested with water, portions of the extracts were withdrawn at stated intervals, and the specific gravities were determined after filtration; it was found that the maximum extraction is finished in two hours, and practically nothing enters into solution during the third hour. At the end of this time, however, there is a considerable increase, arising from diastatic action and from maltose entering into solution. To show that there was no diastatic action during the three hours, comparative mashes were made, one with 0.05 per cent. salicylic acid solution, the other with water. Portions of the first mash were taken at 30 minutes' intervals up to three hours, were filtered at once, the filtrate boiled, again filtered, made up to the original volume, and the specific gravity taken. The aqueous mash, after standing three hours, was treated in the same way. The results showed that there was a gradual extraction which decreased

in amount as the time of digestion was prolonged, and that the specific gravity of the three hours' water mash was about the same as that of the salicylic acid mash at the end of two hours. Consequently, the 0.05 per cent. solution of salicylic acid had a greater extractive power than water, and by means of special experiments the author found that a 0.2 to 0.25 per cent. solution of salicylic acid was required to extract an amount of matter similar to that taken up by water.

When malt was extracted for three hours with water at temperatures of 60°, 70°, 80° F., the matter entering into solution was greater between 70° and 80° than between 60° and 70°, and this arises from the action of diastase on the eroded starch granules.

The above-mentioned experiments demonstrate that, to obtain accurate comparative results, it is necessary to conduct all extractions at one definite temperature for a constant time; and, as a precaution, a solution of salicylic acid sufficient to stop diastatic action may be employed in place of water.

An unsuccessful attempt was made to estimate the ready-formed sugars of malt by determining the loss of gravity which an aqueous malt extract, prepared under standard conditions, undergoes on fermentation. The sugars of the aqueous extract were next compared with the total sugars extracted by alcohol and determined by O'Sullivan's method. The ready-formed sugars in the cold-water mash were estimated by difference and fermentation; in addition to this, the cane sugar was estimated by inversion with yeast, the cupric reduction taken after inversion, and the results, when necessary, corrected for unfermentable, reducing, and optical substances. A close agreement exists between the cane sugar in the alcoholic and aqueous extracts from the same malts. The ready-formed sugars determined by fermentation are greater in the aqueous than in the alcoholic extract; this is also the case with the total sugars estimated after inversion by cupric reduction. These results indicate that there are some other carbohydrate substances insoluble in alcohol but soluble in water, which the author believes are formed simultaneously with the true sugars in the germinating grain; and the same conditions which favour the production of an excess of sugars also favour an excess of these substances. It is therefore not correct to designate the mixture of sugar and carbohydrate matter "ready-formed sugars"; the term "ready-formed soluble carbohydrates" is accordingly employed by the author for the constituents of a cold aqueous extract of malt other than nitrogenous matter, ash, and acid. There is a fairly constant relation existing between the ready-formed soluble carbohydrates determined by difference and the true sugars of a malt, which may be employed for calculating the one into the other. Since no such relation appears to exist between the ready-formed soluble carbohydrates and the sugars determined by fermentation from the cupric reduction, the latter methods may also give inaccurate and misleading results.—J. L. B.

Malt and Beer Worts, Investigations on Nitrogenous Constituents of. E. Ehrlich. *Der Bierbrauer*, 1895, 145—147, 161—163, 177—179.

THE nitrogenous constituents of barley-malt and wort are generally divided into three groups, albumins, peptones, and amides. The last two are derived from the first by the action of the enzyme peptase, and they differ by their greater solubility and power of diffusion. This change, which is known as peptonisation, is of considerable importance in brewing operations, as certain albumins (glutin), which impede or prevent the clarification of beer, are modified and converted into compounds, valuable as yeast foods.

The author has investigated methods of separating the three groups of nitrogenous substances, the influence of the period of germination on the growth of the barley, the effect of washing on the nitrogenous constituents of the wort, and the behaviour of the different nitrogenous bodies towards yeasts.

The possibility of a separation of the different groups of nitrogenous compounds is dependent on their behaviour towards certain reagents. Whilst the albumins are precipitated from their solutions by lead and copper salts, tannin and phosphotungstic acid, the peptones are precipitated only by the last two and the amides by neither.

The total nitrogen was estimated in the residue from 20 c.c. of a wort. 250 c.c. of the same wort were boiled with basic lead acetate, and, after cooling, made up to 500 c.c.; when it had stood for seven or eight hours, the precipitate was filtered, hydrogen sulphide passed into the sulphate, the lead sulphide filtered off, and the nitrogen determined in 40 c.c. of the filtrate. The numbers obtained represent the nitrogen from peptones and amides, and the difference between this and the total nitrogen of the wort, the nitrogen due to albumin. 20 c.c. of tannin solution were next added to 80 c.c. of the filtrate containing peptones and amides; when the solution had remained 12 hours after the removal of the lead, it was filtered, and the nitrogen estimated in the filtrate; it represents that due to amides.

To effect a separation with copper hydroxide and phosphotungstic acid, 20 c.c. of the wort were diluted to 100 c.c., warmed, 10 c.c. of copper hydroxide added, and allowed to stand for 24 hours. The albuminoid precipitate was filtered, 55 c.c. of the filtrate containing the peptones and amides were evaporated, and the nitrogen determined in the residue. To 50 c.c. of the original wort, 10 c.c. of a 10 per cent. solution of sulphuric acid and 50 c.c. of 10 per cent. phosphotungstic acid were added; after 20 minutes the precipitate of albumin and peptone was filtered, and the nitrogen estimated in the residue obtained from 44 c.c. of the filtrate. A comparison of the results reveals the fact that basic lead acetate precipitates more nitrogenous substances than copper hydroxide, and phosphotungstic acid more than basic lead acetate and tannin together.

The peptones and amides appear to have the same value as nutrient material for yeasts, and in this respect are much better than albumin.

Experiments on the influence of germination on the soluble nitrogenous substances of the barley, show that peptonisation of the albumins takes place; and the longer the period of germination, the greater is the amount of nitrogenous bodies rendered soluble. Peptonisation also proceeds during the mashing process, the most favourable temperature being 50° C.—J. L. B.

Sugars, Influence of Temperature on the Polarisation of. Sachs and Xhonneux. *Zeits. Rübenz. Ind.* 1896, 46, 264.

WACHTEL (Oesterr.-Ungar. Zeits. für Zuckerind. und Landwirth. 1878, 7, 42) has observed that sugar solutions polarising 95 per cent., exhibited an average difference of rotation of 0.27° between 10° and 18° C., and he assigned the cause to the expansion of the quartz wedge of the polariscope. Wartze found (*Deutsch. Zuckerind.* 16, 503) in similar solutions a difference of 0.10° for every 2° C. between 2° and 40° C. The authors have made an exhaustive series of experiments on sugar solutions polarising about 95 per cent. between the temperatures of 14° and 26° C., and have confirmed Wartze's numbers. If the flasks containing the sugar solutions be made up to 100 c.c. at the same or even a higher temperature than that at which the solutions are polarised, the differences in the readings are considerably decreased, and this is the case also with diluted sugar solutions. The normal quartz plate employed as a control, gave rotations of 97.8, 97.9, 98.0, 98.1, for 10°—20°, 20°—30°, 30°—40°, 40°—50° C. respectively, thus showing that the influence of temperature is of little account.—J. L. B.

Silk, Weighting Materials in: The Quantitative Estimation of. H. Silbermann. *Chem. Zeit.* 20, 472—473.

THE author has previously described (*Chem. Zeit.* 18, 744—745; this Journal, 1894, 907) the methods of qualitatively examining the weighting materials in silk, and in the present paper he gives directions for their quantitative estimation.

White or Light-coloured Silk.—The sample is boiled several times in distilled water, and in the solution, after inverting cane-sugar by boiling with hydrochloric acid, sugar is estimated by means of Fehling's solution, magnesium

salts by precipitation with sodium phosphate, and sodium sulphate by means of barium chloride. The silk is then reduced to ash, and the ash, after weighing, is dissolved in hydrochloric acid; if tin be the only metal found in this solution, the weight of the ash multiplied by 1.13 gives the weight of hydrated stannic oxide present on the fibre. Another method of estimating the tin consists in igniting the silk with caustic soda and potassium nitrate in a porcelain crucible. (A platinum vessel should not be used, since there is a danger that with insufficient access of air, a reduction to metallic tin might take place with consequent formation of an easily fusible platinum-tin alloy.) The melt is dissolved in water, acidified, precipitated with H_2S , and the sulphide ignited and weighed as SnO_2 .

A special sample of the silk is boiled with dilute hydrochloric acid to dissolve any tannin lakes of tin or other metals, and in the solution, tannin is tested for by the addition of an excess of sodium acetate and a ferric salt. If tannin lakes be present, the estimation of the weighting materials consists in (1) precipitation of tannin from the aqueous solution with gelatin; (2) estimation of tannin in this precipitate, and of sugar, &c. in the filtrate; (3) successive treatment of the silk with dilute hydrochloric acid and sodium carbonate, and precipitation of tannin from both solutions by means of gum solution; (4) ignition of the silk and estimation of metallic weighting. If the ash be not completely soluble in hot moderately concentrated hydrochloric acid, it may contain barium sulphate or silicic acid; if both are present, they may be separated by dissolving the latter in hydrofluoric acid. These substances are estimated by well-known methods.

Dark-coloured Silk may contain in addition to the above weighting materials, compounds of iron and chromium. The ash is ignited with $NaOH$ and KNO_3 whereby tin and chromium are converted into stannates and chromates respectively. These are dissolved out with water, and Fe_2O_3 remains as an insoluble residue; the filtrate is acidified with hydrochloric acid, tin precipitated by H_2S and chromium from the filtrate by $NaOH$.

Black Silk.—The quantitative estimation may be made in two ways, either the weighting is entirely removed from the silk, and estimated by the loss in weight, or the amount of pure silk substance in the sample is calculated from the result of a nitrogen estimation. The latter method gives more accurate results, but is less easy to carry out. According to the first method, the sample is boiled alternately in solutions of caustic soda (20 grms. per litre) and hydrochloric acid (250 grms. per litre), each treatment being repeated 5–6 times. Naturally a certain loss of silk substance must occur, thus causing the amount of weighting to appear too high. By this treatment all foreign substances are removed except a small quantity of metallic compounds (afterwards estimated by ignition) and mere traces of tannin and colouring matter. The silk, if souple or *écru*, is finally scoured with soap, dried and weighed. In all cases the difficulty arises of estimating the loss in weight of the silk on “boiling-off.” This may be taken approximately as 25 per cent. for “boiled-off” silk, 8 per cent. for souple, and 10 per cent. for fancy yarns.

By far the most satisfactory method is the estimation of nitrogen. Weighting materials which contain nitrogen, *e.g.*, gelatin and Prussian blue, are entirely removed by alternately boiling with alkaline carbonate and acid, with the precaution that for souple or *écru* silk, ammonia or ammonium carbonate must be used, and not sodium carbonate. The silk is then dried to a constant weight (about 2 grms.), divided into single fibres, and mixed with soda lime; the mixture is ignited in a combustion tube and the ammonia collected by means of HCl , and estimated volumetrically or as the platinum double salt; or the nitrogen may be estimated by Kjeldahl's method. Pure silk contains 17.6 per cent. of nitrogen; for souple and *écru* this of course includes the fibron and sericin. The amount of weighting is then estimated by difference. The analysis must be very carefully carried out, special care being taken that the reagents used contain no nitrogenous impurities.

Silk fabrics should be separated into warp and weft and these separately analysed; the weft as a rule is much more heavily weighted than the warp.—R. B. B.

Citronellal (Citronellie Aldehyde) Group of Compounds.
Occurrence of, in Essential Oils. F. Tiemann and R. Schmidt. Ber. 1896, 29, 903–926.

THE major portion of this paper is devoted to experimental and theoretical considerations relating to the chemical structure of citronellal, citronellol, &c. (this Journal, 1891, 158, 382; 1892, 935; and 1894, 417). The facts principally bearing on this question are:—

1. Citronellal (as also citronellol, citronellie acid, &c.), on oxidation with chromic acid, yields acetone and β -methyl-adipinic acid—

2. Citronellal, when heated with acetic anhydride, is converted into an isomeric cyclic alcohol, which agrees in most of its properties with, and is shown to possess the same structure as, pulegol. These facts point to the following formulae:—

Citronellal—

Citronellol—

Incidentally, it is shown that citronellol exists in two optically-opposed modifications, which, on oxidation, yield the corresponding *d*- and *l*- β -methyl-adipinic acids ($\alpha = +2$ in 33 per cent. aqueous solution in 100 mm. tube). These acids are in other respects identical, both melting at 84° – 85° C.; but, when mixed in equal proportions and crystallised, an inactive (racemic) form is obtained, which is somewhat less soluble in water, and melts at 93° – 94° C.

Of greater interest is the discovery that citronellol, like geraniol, is a constituent of many essential oils, notably of geranium oils, rose oil, &c., and frequently also of the “geraniol” prepared from them. That these oils contain, besides geraniol, an alcohol, $C_{10}H_{20}O$, has indeed been recognised by other observers (this Journal, 1896, 292), and in the case of rose oil the alcohol in question has been isolated and is known as “rhodinol.” It appears, however, that rhodinol must be regarded as *l*-citronellol, since it yields on oxidation *l*- β -methyl-adipinic acid and is optically the antipode of *d*-citronellol. The following method of detecting and estimating citronellol in admixture with geraniol is stated to give very satisfactory results:—A solution of 100 parts of the sample under examination in 100 parts of absolute ether is cooled and added very gradually to a solution (cooled to -10° C.) of 60 parts of phosphorus trichloride in 100 parts of ether. During this operation the temperature must not be allowed to rise above 0° C. The mixture is allowed to stand for 4–5 days at the ordinary temperature, and is then poured out on crushed ice, the ethereal layer washed several times with ice-water and agitated vigorously with dilute caustic soda solution, which extracts from it citronellol (in the form of a chlorinated phosphorus ester-acid), leaving behind geranyl chloride, &c. The soda solution is shaken once or twice with ether to remove impurities, rendered strongly alkaline, and steam-distilled in order to separate the liberated citronellol. The yield of citronellol is quantitative from samples containing not less than 20 per cent. of geraniol. *d*-Citronellol may be readily prepared in this way from citronella oil. The latter is first treated with sodium amalgam in order to reduce the citronellal present, and the above process directly applied to the resulting mixture of alcohols. Appended are some results obtained by the method:—

Turkish Rose Oil.—The alcohols present (80 per cent.) consisted of:—Geraniol, 75 per cent.; *l*-citronellol, 25 per cent. The latter exhibited the following properties:—B. pt. 113° – 114° C. under 15 mm. pressure; sp. gr. at 20° C. = 0.8612; refractive index, $n_D = 1.45789$; $\alpha = -4^{\circ} 20'$ in 100-mm. tube (*d*-citronellol, b. pt. 117° – 118° under 17 mm. pressure; sp. gr. at 17.5° C. = 0.8565; refractive index, $n_D = 1.45659$; $[\alpha]_D = +4^{\circ} 0'$).

Spanish Geranium Oil.—Total alcohols, 70 per cent., consisting of:—Geraniol, 65 per cent.; *d*- and *l*-citronellol, 35 per cent., the *l*-modification predominating.

African Geranium Oil contains 75 per cent. of alcohols, composed of geraniol, 80 per cent.; *d*- and *l*-citronellol, 20 per cent.

Reunion Geranium Oil.—Alcohols, 80 per cent., containing geraniol, 50 per cent.; *d*- and *l*-citronellol, 50 per cent. (contaminated with traces of an alcohol resembling, and probably identical with, linalool). Reunilol, obtained by Hesse from reunion geranium oil, and considered by him to be a distinct alcohol, was found also to be a mixture of geraniol and citronellols, the *l* variety predominating.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Bidiphenylene Ethylene and Bidiphenylene Ethane.

C. Graebe and H. Stindt. Annalen, 1896, **291**, 1—8.

In a previous communication (this Journal, 1893, 186) one of the authors referred to the red hydrocarbon $C_{26}H_{12}$ obtained by De la Harpe and van Dorp by passing fluorene over lead oxide. He also described its preparation in detail, and the authors, in repeating the experiments, succeeded in obtaining most successful results as far as yield is concerned. It was found that the formation of bidiphenylene ethane takes place in the first part of the reaction; this compound is then further oxidised into the ethene body. When bidiphenylene ethene is fused with potash, *o*-diphenylcarboxylic acid is obtained. It forms white crystals, melting at 110° . Nitric acid gives rise to the formation of an additive compound, crystallising in yellow needles, which melt at 184° — 185° . It is reconverted into the red hydrocarbon on boiling in an alcoholic solution of potash. The *dibromide* mentioned in the former paper is decomposed when heated in steam at 150° , with partial formation of the ether of bidiphenylene ethene.

Bidiphenylene ethane, $C_{26}H_{14}$, is obtained by heating fluorene with lead oxide at 250° — 280° for two hours. It melts at 246° (corr.), dissolves sparingly in alcohol and ether, more readily in hot benzene and glacial acetic acid.

—D. B.

Sulphochromous Acid, a New Chromium Compound.

A. Recoura. Bull. Soc. Chim. 1896, **15**, 315—321.

A new compound, termed by the author sulphochromic hydrate, is formed by heating chromic sulphate (1 mol.) with sulphuric acid (4—6 mols.) at 115° — 120° for 1—2 days; or by heating chromotetrasulphuric acid—

(Comptes rend. 1893, **9**, 586), at 140° — 150° , so long as sulphuric acid is evolved. In the latter case, the compound is obtained as a grey powder, of the formula—

It differs from the chromosulphuric acids previously prepared, in the following respects:—

- (i.) Its aqueous solution is opalescent and nearly colourless.
- (ii.) On standing in a closed vessel, its aqueous solution gelatinises.
- (iii.) A freshly prepared solution when heated to 100° , gelatinises, and then deposits a flocculent precipitate.
- (iv.) A pale green precipitate is produced on adding any strong acid to its aqueous solution.
- (v.) It precipitates all metallic elements and ammonia, the precipitates having the general formula—

in which M represents a monovalent element.

The bases in these precipitates are combined with the chromic hydroxide and not with the sulphuric acid.

Sulphochromic hydrate is a powerful acid. It displaces sulphuric acid from its salts.—E. B.

Sodium Thiosulphate, Solubility of, in Alcohol.

P. Parmentier. Comptes rend. 1896, **122**, 135—137.

THE three modifications of sodium thiosulphate (ordinary, modification of m.p. 32° , and superfused) vary in their solubility in alcohol. Thus, in 80 per cent. alcohol they dissolve in the ratio of 11.4:10.6:7.1, these being the numbers of c.c. of a 0.1 per cent. solution of iodine required to oxidise 10 c.c. of the filtered alcoholic solutions. In the case of the superfused salt, the solubility is influenced by mass action, the solubility increasing with the volume of alcohol employed.—E. B.

Schlippe's Salt, Preparation of. L. Prunier. Journ.

Pharm. Chim. **16**, 289—290.

Purified antimony sulphide is melted with a third of its weight of sulphur. The product, principally consisting of pentasulphide, is cooled, powdered, and heated to boiling with a solution of crystallised sodium monosulphide (2 parts in 5 parts of water). The penta-sulphide combines with the sodium sulphide forming sodium sulphoantimoniate (Schlippe's salt). The solution is cooled, filtered off from a trace of black oxysulphide and evaporated down, when the Schlippe's salt crystallises out.—J. G. W.

Magnesia, A Basic Nitrate of. G. Didier. Comptes

rend. 1896, **122**, 935—936.

To a solution of 200 grms. of the hydrated neutral nitrate of magnesia in 150 c.c. of water, maintained at 100° C., 10 c.c. of pure caustic magnesia,—obtained by calcining the bicarbonate for some hours at 350° — 400° C.,—were gradually added. The greater part of the magnesia dissolved, the temperature of the liquid was then raised to 150° and the solution filtered. On cooling in well-corked flasks, the solution remained for some time in a state of supersaturation, but gradually became almost solid from the formation of a flocculent precipitate. Separated by filtration with the pump and subsequently pressed between filter-paper, this precipitate had the composition $3MgO$, N_2O_5 , $5H_2O$. Cold water decomposes this salt completely into magnesium nitrate and magnesium hydrate. Absolute alcohol has a similar effect.—L. T. T.

New Orydase or Soluble Oxidising Vegetable Ferment.

G. Bertrand. Bull. Soc. Chim. 1896, 793—797.

It is well known that the juice of beet root rapidly turns red and finally black on exposure to air, and this property is shared by the juice from other vegetable roots, such as dahlia, potato, and from certain fungi, such as *russula nigricans* (mushroom). The coloration is due to the oxidation of the tyrosin under the influence of a soluble ferment different from laccase, which the author terms tyrosinase. This substance, which is very unstable, cannot be extracted from beet- or dahlia-root; but certain fungi, such as *russula foetens*, *r. virescens*, *r. cyanoxantha*, &c., when macerated and extracted with water, give a solution which blackens tyrosin with absorption of oxygen. Tyrosin, however, can be extracted from the juice of dahlia tubers, and is identical with that of animal origin. The yield is about 0.5 gm. from a litre of extract.—T.A.L.

New Books.

JAHRBUCH DER ELEKTROCHEMIE. Berichte über die Fortschritte des Jahres 1895. Im wissenschaftlichen Theile, bearbeitet von Dr. W. NERNST; Im technischen Theile, bearbeitet von Dr. W. BORCHERS. II. Jahrgang. Verlag von Wm. Knapp, Halle a.S. 1896. Price 12s. H. Grevel and Co., 33, King Street, Covent Garden, London, W.C.

8vo volume in paper cover, containing preface, table of contents, text filling 280 pages, and illustrated with 197 engravings, and alphabetical indexes of authors and subject-matter. Part I., or the portion of the work relating to the Science of Electrochemistry, for which Dr. Nernst is responsible, contains 36 pages; whilst Part II., which has been written by Dr. Borchers and relates to Electrochemical Technology, extends from page 39 to page 280.

The classification adopted, indicates the nature and general trend of the work, and is as follows:—I. SCIENTIFIC

PORTION.—Electrolytic Conductivity and Dissociation. Theory of Galvanic Current Production and Polarisation. Electro-capillarity. Instruments for Electrochemical Measurement. II. Special and Technical Electrochemistry. Production of Electrical Energy. Accumulators. Electromagnetic Preparation. Electrothermic Apparatus and Methods. Metalloids. Metals. A. Special Metallurgy. B. Investigations and Propositions of General Character. C. Metallurgical Processes. Inorganic Compounds. Organic Compounds. Each of the various chapters connected with Electrochemical Technology ends with an appropriate list of patents, German, American, and British.

CHEMISCH-TECHNISCHES REPERTORIUM. Uebersichtlicher Bericht über die neuesten Erfindungen, Fortschritte und Verbesserungen auf dem Gebiete der technischen und industriellen Chemie, mit Hinweis auf Maschinen, Apparate und Literatur. Herausgegeben von Dr. EMIL JACOBSEN. 34. Jahrgang. 1895. Zweites Halbjahr. Zweite Hälfte. Schluss. Mit in den Text gedruckten Illustrationen. Hermann Heyfelder, R. Gaertner's Verlagsbuchhandlung, Schöneberger-str. 26, Berlin, S.W. H. Grevel and Co., 33, King Street, Covent Garden, London.

The second issue for the second half-year of 1895 of Dr. Jacobsen's Repertory of Chemical Technology, containing reports of the progress of the following branches of chemical industry:—I. Food-stuffs. II. Paper. III. Photography. IV. Residuals; Manures; Disinfection and Sanitation. V. Soaps. VI. Explosives and Matches. VII. Preparation and Purification of Chemicals. VIII. Chemical Analysis. IX. Apparatus, Machinery, Electrotechnology and Thermo-technology. X. Appendix. Adulteration of Trade Products, &c. New Books.

This being the closing number for 1895, an alphabetical index is given. The volume contains 234 pages of matter, and is illustrated with woodcuts.

NITRO-EXPLOSIVES. A Practical Treatise concerning the Properties, Manufacture, and Analysis of Nitrated Substances, including the Fulminates, Smokeless Powders, and Celluloid. By P. GERALD SANFORD, Consulting Chemist to the Cotton Powder Co., Limited. Crosby, Lockwood, and Son, 7, Stationers' Hall Court, Ludgate Hill. 1896. Price 9s.

This work, an 8vo volume, bound in cloth, is devoted to the subject of the properties, manufacture, and methods of analysis of the various nitro-explosives. It numbers 264 pages of subject-matter, illustrated with 43 wood engravings, and terminates with an alphabetical index of subject-matter. The subject-matter is divided into chapters, which treat of the following leading themes, taken in the order given:—I. Introduction. II. Nitroglycerin. III. Dynamite. IV. Nitro-cellulose, &c. V. Nitrobenzol, Roburite, Ballite, Picric Acid, &c. VI. The Fulminates. VII. Smokeless Powders in General. VIII. Analysis of Explosives. VIII. Firing Point of Explosives. IX. Determination of the Relative Strength of Explosives.

CHEMISTRY IN DAILY LIFE. Popular Lectures. By Dr. LASSAR-COHN, Professor in the University of Königsberg. Translated by M. M. PATTERSON MUIR, M.A. H. Grevel and Co., 33, King Street Covent Garden, London. 1896. Price 6s.

This work commences with the translator's preface, and a table of contents, after which follow the text, covering 316 pages, and the alphabetical index. The work is illustrated with 21 wood cuts. As stated by the translator, "This book embodies the substance of a course of lectures delivered by Dr. Lassar-Cohn, to a society in Königsberg, modelled on the celebrated Humboldt Academy of Berlin." There are 12 lectures in all, and the leading idea in each of these will be found in the following synopsis of contents:—LECTURE I. Breathing, Physics and Chemistry, Air, Combustion, &c. II. Nature of Flame, Candles, Illuminating Agents, &c. III. Food of Plants, Manuring, Food of Men and Animals, &c. IV. Mixed Diet, Butter, Margarine, Starch, &c. V. Quantity of Food to be Consumed, Fermentation, Wines, Alcohol. VI. Wine Vinegar, Wood Vinegar, Acetic Acid,

Explosives, &c. VII. Tanning, Leather, &c., Dyestuffs and Dyeing, &c. VIII. Oil Painting, Oils, Varnishes, and Inks, &c. IX. Potash and Soda, Sulphuric Acid. X. Glass, Mirrors, Clay, Bricks, Mortars, &c. XI. Noble and Base Metals, Ores, Metallurgy. XII. Alloys, Coinage, Alkaloids, Methane, Acetylene, Artificial Febrifuges, &c.

FORTSCHRITTE DER THEERFARBENFABRIKATION UND VERWANDTER INDUSTRIEZWEIGE. 1890—1894. An der Hand der systematisch geordneten und mit kritischen Anmerkungen versehenen Deutschen Reichs-Patente. Dargestellt von Dr. P. FRIEDLÄNDER, Vorstand der chemischen Abtheilung des k.k. technologischen Gewerbemuseums in Wien. Dritter Theil. Verlag von Julius Springer, Berlin. H. Grevel and Co., 33, King Street, Covent Garden, London. 1896. Price 2s.

LARGE 8vo volume in paper cover, containing dedication (to Prof. Ad. von Baeyer), preface, table of contents, and subject-matter filling 1024 pages. The work ends with a full alphabetical index of subject-matter, preceded by one of patentees, and this again by a list of patents taken out in the period 1890—1894, with references to the abstracts of these patents given in the body of the work. The work as a whole is a compilation of all the patents relating to dyestuffs, the materials therefor, and to various other organic chemicals. The classification is as follows:—Intermediate Products of the Coal-Tar Industry (page 1 to 66). Di- and Triphenylmethane Colouring Matters (page 67 to 187). Anthracene Colours (page 188 to 273). Indigo Blue (page 274 to 287). Acridine (Quinoline) Colours (page 288 to 297). Quinone-imido Colours (page 298—401). Naphthalene Derivatives (page 402 to 520). Azo Colours (page 521—801). Nitro- and Nitroso Colours (page 802 to 812). Pharmaceutical Products (page 813 to 998). Appendix (page 999 to 1017).

With regard to the azo colours generally, these may be more particularly sub-divided as follows:—Wool Dyestuffs (534 to 602). Diazo Dyestuffs Dyeing on Mordants (608 to 650). Cotton Dyestuffs from Benzidine, Tolidine, &c. (652 to 733). Cotton Dyestuffs of the Bismarck Brown type, Primuline Colours, &c. (737 to 800). The Pharmaceutical Products may be more particularly classified as follows:—Hydroxycarbonic Acids (821 to 843). Pyrocatechol and its Derivatives (844 to 869). Iodised Compounds (869 to 877). Scented Substances (878 to 900). Saccharine and Similar Bodies (900 to 906). Compounds of the Phenacetine Type (908 to 921). Pyrazol Derivatives (925 to 945). Piperazine and its Homologues (946 to 955). Quinoline- and Isoquinoline Derivatives, &c. (957 to 997).

A DICTIONARY OF CHEMICAL SOLUBILITIES. INORGANIC. By ARTHUR MESSINGER COMEY, Ph.D. Macmillan and Co., London and New York. 1896. Price 15s.

8vo volume, containing preface, explanatory preface, list of abbreviations and references, and subject-matter covering 515 pages.

In the preface it is pointed out that whilst Peter Shaw, of London, in 1731, first planned a list of Solubilities, based on the fact that "water as a menstruum dissolves more of one body and less of another," it was many years later before Prof. F. H. Storer, of America, first undertook to carry out the idea. This he did in his "Dictionary of Solubilities of Chemical Substances," published in 1864. The limited edition of this work was, however, soon exhausted, and the book went out of print. Hence, as the author shows, after the lapse of 30 years, practically a new work needed compilation. No less than 120 journals, dictionaries, &c., are mentioned as works of reference. The author points out that it has been found impracticable to draw a sharp line between solution and decomposition, and the term "Soluble" has in general been used where a solution of some sort is formed by the action of the solvent. The author draws attention to the prevailing lack of homogeneity of the existing nomenclature, and states that "his aim has been in all cases to follow the best usage rather than to make an absolutely homogeneous system of nomenclature out of the existing confusion." With regard to the formulae, those used have in most cases been those adopted by the authors from whom they have been taken.

DIZIONARIO DI MERCOLOGIA AD USO DEL COMMERCIO. ARTI ED INDUSTRIE. Descrizione, caratteri, provenienza, estrazione, usi ed applicazioni dei prodotti naturali e dell'industria, saggi per identificarli e riconoscerne le sofisticazioni, con speciale riguardo ai loro dazi doganali. Del Dott. VITTORIO VILAVECCHIA, con la collaborazione dei Dott. G. FARRIS e Prof. C. HANNAU. A. Donati, Genoa, Italy. H. Grevel and Co., 33, King Street, Covent Garden, London. 1896. Price 15 frs.

ITALIAN Dictionary of Chemical Technology in the form of a large 8vo volume, in paper covers, with preface, table of explanations and abbreviations, and subject-matter filling 785 pages, an alphabetical index concluding the work. Besides the Italian names of the substances described, and immediately following them, are also given the French, German, and English names. For example, the heading for Aluminium Salts is thus given:—**Aluminio** (Salt di). (Sels d'Aluminium. Aluminium-salze. Aluminium Salts.)

Trade Report.

EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

PRODUCTION OF SALT IN RUSSIA.

The United States Consul-General at St. Petersburg states that when deposits of salt were discovered at Bardymkul, in the region of Ferghana, Turkestan, in the fall of 1895, Belgian capitalists without delay sent out their engineers to investigate the strength of the beds, and to report thereon. The examination not only confirmed what was claimed before, but proved the beds to be richer than at first described. The engineers estimated that an area of 2 square versts (1 verst = 0.663 mile) contained a milliard poods (36,112,000,000 lb.) of salt. As soon as the engineers submitted their report, the capitalists procured, at the close of 1895, a permit from the Russian Government for the working of these salt beds. This they readily received, because just at that time the new regulations of the Ministry of the Interior, concerning the leasing of Government salt beds, came into force. The company began work in January 1896. The salt is gained by dynamite explosions, then put into bags, and sent by camels to Samareand, 239 miles, and thence, by the Transcaspiian Railway, distributed to the different towns on this line; and, also, over Usun-Ada, as far as A-trakhan, and to Kura, mainly for salting caviar. The salt is of excellent quality, as, according to an analysis, it is superior to the best quality of English salt. It is especially fit for salting caviar and sausage casings, because it leaves no spots after the salting. Russia imports about one and half million poods (54,168,000 lb.) of foreign salt through the ports of the Baltic Sea, which this company hopes to supply, because it expects to be able to deliver the Russian salt at St. Petersburg at 2.40 roubles per pood. This price will be the same as is paid for the best English salt, with the difference that the English salt contains a percentage of other chemical substances, whereas the Bardymkul salt is entirely pure. It is the intention of this company to supply India with salt. India offers an immense market, having no salt of its own. It is stated that the 80,000,000 poods (2,888,960,000 lb.) which are yearly imported are not sufficient to supply the demand. Salt costs in India, without the duty, 3.87 roubles per pood. Under these conditions the company will have an excellent chance for a large sale of salt in India, because it can have the salt transported at cheap rates through Samareand, Usun-Ada, Baku, Batoum, &c. It will have a still better chance when the Samareand-Kokand-Marghelan Railway, with a line to Krasnovodsk, on the Caspian Sea, is built, for the salt beds will be only from 13 to 15 miles from the railroad station at Potar of the new line, and 1,100 miles by rail from Usun-Ada. On the Transcaspiian Railway a new reduced tariff of 23.45 copecks per pood is now in force for all kinds of freight from Samareand to Usun-Ada, and from the latter place to Baku the freight on salt amounts to only 4 copecks per pood. Such cheap rates will give the Bardymkul company an advantage in both the home and foreign markets.

EXPORTS OF CAOUTCHOUC FROM PARA (BRAZIL).

Board of Trade Journal, July 1896, 72.

A despatch has been received from H.M. Chargé d'Affaires in Brazil, enclosing table of the exports of caoutchouc from Para during the past 30 years, which has been prepared from official sources.

Years.	Value.
	Milreis.
1865-66	3,810,914
1870-71	6,563,196
1875-76	5,191,001
1880-81	11,491,709
1885-86	14,312,000
1890-91	19,067,528
1891-95	37,417,374

GENERAL TRADE NOTES.

PARA RUBBER IN CEYLON.

Board of Trade Journal, July 1896, 94.

The *Ceylon Observer* notes that an interesting experiment in the cultivation of Para rubber is being made on the Halwatura estate, in the Kalutara district. About a year ago Messrs. Finlay, Muir, and Co. purchased some 50,000 plants, which were planted on Halwatura by Mr. Hendry. The trees, it is said, show a surprising growth and, like those on the Government's experimental plantation in the same district, promise well.

CHROME MINES IN TURKEY.

Chamber of Commerce Journal, June 1896, 107.

The working of chrome mines, which are largely found in Macedonia, has, according to the French Consul at Salonica, taken a certain development by reason of the facilities for transport resulting from the creation of railways, which have enabled exporters to deliver this ore at the ports of embarkation on conditions permitting them to compete on various markets with other producing countries. The chrome mines at present worked are mostly situate in the Monastir and Kossovo regions of Macedonia, and the ore extracted contains, according to analyses to which it has been submitted, some 45 to 55 per cent. of oxide of chrome. The best qualities give the following composition:—Oxide of chrome, 55 per cent.; protoxide of iron, 13 per cent.; alumina, 10 per cent.; magnesia, 15 per cent.; and silica, 7 per cent. In poorer ores there is less oxide of chrome, alumina, and magnesia, and consequently more iron and silica. Germany takes first place as a customer for the ores, followed by England and Austria; a long way after France takes a few tons. Salonica is the chief dealing place, each year's export reaching to 10 or 82 thousand tons, which are sold at an average rate of 107 frs. 50 c. per ton f.o.b. in one of the ports of the importing country. The several conditions of payment are: 75 per cent. of the value against documents, and the remainder after analysis by an expert agreed by the parties. An increase or decrease of 3 frs. in the value per degree of richness of the ore is made according as the expertise shows the ore to be richer or poorer. Macedonian chrome, in addition to its richness in oxide, is said also to possess the further advantage of being very friable.

Total value.....	2,822,368	2,840,870

Monthly Patent List.

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

- 13,141. F. Stretch, E. J. Kennedy, and J. Watson. Improvements in apparatus for cooling liquids. June 15.
- 13,279. R. A. Lister and G. E. Suoxell. Improvements in or connected with centrifugal dryers. June 16.
- 13,386. F. Grumbacher. Improved aeration and fermentation apparatus for yeast, indigo, and the like. Complete Specification. June 17.
- 14,001. C. J. Brown. Improvements in condensing and cooling apparatus. June 24.
- 14,478. F. Dehaitre. Improvements in apparatus for drying and finishing fabrics. June 30.
- 14,575. W. R. M. Semple. Improvements in apparatus for heating water and other liquids. July 1.
- 14,609. M. Stanbrook. Apparatus for cooling air for use in refrigerating. July 2.
- 14,774. O. Guttmann. Improvements in apparatus for mixing or obtaining reactions between liquids and gases. Complete Specification. July 3.
- 14,951. E. J. Duff and J. Brock. Improvements in evaporating brine and other solutions, and in apparatus therefor. July 6.
- 14,952. T. Glover and J. Brock. Improvements in and apparatus for evaporating solutions with multiple effect. July 6.
- 15,335. E. H. Holmes and W. B. Woodruff. Improvements in gauges. July 10.
- 15,374. J. Pogson. Improvements in surface condensers. July 11.
- 15,469. J. Spencer, H. S. Smallman, and T. H. Spencer. A new or improved annealing and drying furnace. July 13.
- 15,488. F. H. Haviland, A. Holloway, J. B. Collier, and W. H. Murch. A new or improved furnace. July 13.
- 15,572. C. H. Lloyd. Apparatus for consuming smoke from furnaces. July 14.

- 15,671. W. Waddell and D. Waddell. See Class II.
- 15,682. B. T. Laey. Improvements in roasting furnaces. Complete Specification. July 15.
- 15,721. W. H. Watkinson. Improvements in steam boilers and in vessels for heating and cooling fluids. July 16.
- 15,745. K. R. Smith. An improvement in superheaters. July 16.
- 15,757. P. M. Justice.—From H. F. Atkinson. Improvements in apparatus for injecting vapour or gas into furnaces. Complete Specification. July 16.
- 15,797. E. C. Mills. An improved apparatus for cooling water for condensing and other purposes. July 17.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

- 13,896. F. Bornemann-Zix. Apparatus for the production of superheated steam. June 3.
- 15,581. D. Richards. Filtering material. June 24.
- 15,765. H. H. Lake.—From E. de Moerloose. Improved process of chemical decoloration and apparatus for use therein, applicable for the treatment of grain and other substances. July 15.
- 20,426. P. C. Hewitt. Evaporators. July 22.
- 24,007. J. Y. Johnson.—From E. Bailly. Machines for crushing or reducing lime, cement, minerals, and the like. July 8.

1896.

- 10,431. J. Fielden. Apparatus for drying wool and other fibrous material. June 24.
- 11,739. O. Guttmann. Apparatus for softening and purifying water. July 8.
- 12,643. E. Porak. Method of and apparatus for washing and compressing sulphurous acid and other gases or fumes. July 15.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

- 13,147. J. E. Atkinson and J. M. Labouchere. Improvements in automatic apparatus for the manufacture of acetylene gas. June 15.
- 13,223. F. Bongère. Improvements in the manufacture of candles. June 16.
- 13,255. W. L. Voelker. Process of manufacturing hoods or mantles for incandescent gas-lights. Complete Specification. June 16.
- 13,256. W. L. Voelker. Hoods, mantles, or gratings for incandescent gas-lights. Complete Specification. June 16.
- 13,385. W. P. Thompson.—From V. Briquet and Co. Improvements in burners for acetylene gas. June 17.
- 13,398. H. Guépin. Improvements in acetylene gas-lamps. June 17.
- 13,511. A. E. Bowers. Improvements in regulators and gas-holders for acetylene gas. June 18.
- 13,557. F. H. Haviland, A. Holloway, and J. B. Collier. An improved apparatus for generating, purifying, storing, and supplying at a uniform pressure acetylene gas. June 19.
- 13,648. J. Musso. Portable and hygienic incandescent lighting wherein the evaporation of hydrocarbons is produced under pressure. Complete Specification. June 20.
- 13,659. J. F. Duke. Improvements in the manufacture of mantles or incandescing bodies for incandescent gas-lamps. June 20.
- 13,736. H. Cuinat. An automatic generating apparatus for production of acetylene or other gas. June 22.
- 14,009. E. Fatham. Improvements in means for obtaining light and heat. June 24.
- 14,213. A. Pengeot. A new system of air carburetter. Filed June 26. Date applied for April 13, 1896, being date of application in France.

14,278. F. P. J. Ackermann. Improvements in apparatus for producing acetylene gas. Complete Specification. June 27.

14,365. C. Killing. Improvements relating to incandescence bodies for incandescent gas-lighting. June 29.

14,448. N. Caro and W. Sahlmann. Improvements in the manufacture of incandescent bodies, or mantles, for lighting purposes. Complete Specification. June 30.

14,740. P. Cannell-Bunn. Improved mantles for gas and other burners. July 3.

14,773. W. B. Hartridge. An improvement in the manufacture of fuel blocks. July 3.

14,845. R. Langhans. Improvements in the manufacture of incandescent media for use in incandescent gas-lighting. July 4.

14,929. A. H. J. Schülke. New or improved apparatus for the production and combustion of acetylene for illuminating purposes. Complete Specification. July 6.

14,936. A. Zendroni. Improvements in the manufacture of briquette fuel. July 6.

14,941. H. Strache. The manufacture or preparation of improved odorizing substances for artificially imparting odour to gases. July 6.

14,943. H. Strache. An improved process and apparatus for the removal of sulphuretted hydrogen from gases or gaseous mixtures. July 6.

15,037. W. F. Stanley. Rendering candle and the like wicks waterproof. July 7.

15,064. G. F. Redfern.—From La Compagnie Continentale d'éclairage par le gaz acétylène et ses applications industrielles. Improvements in apparatus for the production of acetylene. July 7.

15,122. F. H. Haviland, A. Holloway, J. B. Collier, and W. H. Mureh. An improved apparatus for generating acetylene gas. July 8.

15,139. G. Isaac. A process for rendering acetylene gas inactive when brought into contact with metals with which it forms explosive compounds. July 8.

15,160. E. Oldenbourg.—From R. Mondos. New or improved method of and apparatus for preparing illuminant appliances employed in the production of light by incandescence. July 8.

15,167. M. Meyer. Improvements in incandescent light burners. Complete Specification. July 8.

15,189. G. W. Weatherhogg. Improvements relating to the burning of hydrocarbons for heating and lighting purposes, and to apparatus therefor. July 9.

15,254. J. Gale. Means for the prevention of explosion in the use and transport of petroleum and like inflammable oil. July 9.

15,324. C. Schuidt. Impregnating fluid for incandescent mantles. July 10.

15,332. A. R. Nisard and A. Serigiers. Improvements in incandescent mantles for gas and other burners. July 10.

15,338. E. Mann. Improved apparatus for the production of ozone. July 10.

15,343. W. A. Tilden. Improvements in the manufacture of oxygen from the atmosphere. July 10.

15,500. R. J. Eiffe.—From F. Meyer and Co. Improvements relating to the preparation of incandescence bodies. July 13.

15,567. C. Weygang. Improvements in the manufacture of artificial fuel. July 14.

15,651. D. Whalley and J. Hacking. Improvements in acetylene gas store generators. July 15.

15,671. W. Waddell and D. Waddell. Improvements in assisting combustion, preventing smoke, and economising fuel, and in the means employed therefor. July 15.

15,962. F. S. Thorn and C. Hoddle. Improvements in apparatus for generating, storing, and cooling acetylene gas. July 18.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

13,764. A. J. Boulton.—From C. Dellwick. Process and apparatus for producing water-gas. July 22.

14,460. H. Howell. Apparatus for the production of combustible gas. June 24.

14,682. J. Bowing. Coking processes. July 8.

15,048. W. Foulis. Apparatus for the manufacture of gas. July 15.

15,659. The Economical Gas Apparatus Construction Co., Lim., and L. L. Merrifield. Apparatus for the manufacture of carburetted water-gas. July 8.

19,183. T. R. Shillito.—From C. M. Rompler and H. Axmann. Means for automatically regulating the mixture of gas and air for incandescent gas-lighting and for heating purposes, and for suppressing the noise made by the inrush of air when incandescent gas-lights are turned low. July 1.

23,170. F. Thuman. Gas generators. July 8.

1896.

3142. F. S. Thorn and C. Hoddle. A new and improved acetylene gas generator and container. July 8.

6008. F. S. Cripps. Apparatus for evaporating oil or other liquids, and mixing the vapours produced with coal-gas. July 8.

6999. A. Hussener. Horizontal coke ovens. July 15.

7226. G. G. Schroeder. Gas-enriching apparatus. July 1.

8304. C. Bourquin, J. Besson, and P. H. P. de Reneville. Manufacture of briquette fuel. July 8.

9922. J. Sibley. Apparatus for making, lighting, and heating gas. June 24.

10,822. H. Kirkham. Improvements in scrubber washers for removing impurities from gas. June 24.

11,706. E. F. J. C. Bauweraerts. Process and apparatus for purifying acetylene gas. July 15.

12,683. H. A. Daroy. Manufacture or production of acetylene gas and apparatus therefor. July 15.

13,255. W. L. Voelker. Process of manufacturing hoods or mantles for incandescent gas-lights. July 22.

13,256. W. L. Voelker. Hoods, mantles, or gratings for incandescent gas-lights. July 22.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

13,118. A. Bang.—From G. A. Dahl. Improvements in the production of dyestuffs for wool. June 15.

12,743. H. Imray.—From F. Petersen. Manufacture of substantive cotton dyestuffs from benzidine sulpho acids. Complete Specification. June 22.

13,744. O. Imray.—From The Society of Chemical Industry in Basle. Manufacture of new disazo, trisazo, and polyazo colouring matters. Complete Specification. June 22.

14,114. I. Levinstein and Levinstein, Lim. Improvements in and connected with azo colouring matters. June 26.

14,115. I. Levinstein and Levinstein, Lim. Production of a naphthylendiamine-mono-sulpho acid and of colouring matters derived therefrom. June 26.

14,563. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik. The manufacture and production of mordant-dyeing colouring matters and of intermediate products relating thereto. July 1.

14,931. G. B. Ellis.—From La Société Chimique des Usines du Rhone, anciennement G. P. Monnet et Cartier. Improvements in the manufacture of pyrocatechin-sulphonic acid and intermediate products. July 6.

14,955. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik. The manufacture and production of new products and colouring matters from aromatic nitro derivatives. July 6.

15,294. W. E. Heys.—From The Chemische Fabrik vormals Sandoz. The manufacture or production of polyazo colouring matters. July 10.

15,412. A. Savage. A compound mixture for cleaning and dyeing wearing apparel. July 11.

15,493. G. Cerekel. Preparation of ortho-sulphamine benzoic acid. Complete Specification. July 13.

15,527. W. H. Claus, A. Rée, and L. Marchlewski. Manufacture of new amido bases and azo colouring matters therefrom. July 14.

15,687. O. Imray.—From H. Traub and Co. Manufacture of organic compounds of carbonic acid. July 15.

15,953. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik. The manufacture and production of new dyes relating to the oxyphenanthronaphthazine series, and of new intermediate products and materials therefor. July 18.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

14,488. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. The manufacture or production of chemical compounds and dyestuffs derived from phenolic bodies. June 24.

14,494. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brünig. Manufacture of azo colouring matters. June 24.

14,687. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. The production of dyestuffs. June 10.

16,217. C. D. Abel.—From The Actien Gesellschaft für Anilin Fabrikation. Manufacture of colouring matters of the rosinduline series. July 1.

17,260. B. Willcox.—From The Badische Anilin und Soda Fabrik. Manufacture of dis- and polyazo dyes by oxidation. July 1.

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATIONS.

13,209. T. Ford. Improvements in the manufacture of woven fabrics. June 16.

13,273. A. S. Oetzmann and S. J. Narracott. Improvements in the manufacture of inlaid fabrics for covering floors and other surfaces, and in apparatus used for this purpose. June 16.

13,707. T. E. Briggs and E. Webb. Improved apparatus for polishing and drying yarns, threads, twines, or cords. June 22.

13,815. W. Warburton. Improved method of extracting vegetable fibres. June 23.

14,090. L. Johnstone and D. Scott. Improvements in or relating to cellulose, and in the manner and means of applying same for dressing or finishing textile fabrics, also applicable to other purposes. June 25.

14,760. G. C. Dymond.—From Erste Deutsche Patent-Linoleum-Fabrik. Improved calendering machine for the production of running linoleum with inlaid coloured stripes. July 3.

14,880. S. H. Hodges. Improvements in the art of segregating the fibres contained in peat. July 6.

15,893. J. Waugh.—From Amos and Co. Improvements in the method of waterproofing fabrics made of fibre, paper, tissues, and the like. July 18.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

13,138. E. Heberlein. Improved process and apparatus for the production of colours with silk-like gloss on vegetable fibres and textile fabrics; also on wool, india-rubber, leather, wood, metal, and other substances. Complete Specification. June 15.

13,366. L. Armanni. Improvements in and relating to receptacles for colouring or dyeing materials. June 17.

14,252. A. Endler. A new or improved process for bleaching cotton and cotton goods. Complete Specification. June 27.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

21,032. W. Hepworth Collins. Apparatus and plant for scouring, bleaching, dyeing, impregnating, digesting, drying, carbonising, and otherwise treating cotton, wool, silk, jute, reed, china grass, and other fibrous materials in a raw, manufactured, or partly manufactured state. June 17.

1896.

8318. C. M. White.—From The Electro Waterproofing and Dye Fixing Co. Art of fixing dyes in fabrics. June 24.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

13,244. A. Crossley and H. A. Allport. Improvements in the manufacture of ferric oxides. June 16.

13,446. F. H. Bowman, J. J. Howitt, J. Knowles, and T. A. Reid. Improvements in and relating to the manufacture of carbonates of soda. June 18.

13,844. J. Brock and F. Hurter. Improvements in recovering sulphur from sulphuretted hydrogen. June 23.

13,881. W. R. King and E. Wyatt. An improved process for the manufacture of calcium carbide. Complete Specification. June 23.

14,002. O. Imray.—From Goerlich, Wichmann, and Co. Manufacture of cyanate salts. June 24.

14,389. J. Morrison, W. H. Richmond, and J. Brock. Improvements in obtaining caustic lime from lime mud. June 29.

14,507. M. Levy. A process of producing muriate of ammonia. June 30.

15,489. F. H. Haviland, A. Holloway, J. B. Collier, and W. H. Murch. An improved method of and apparatus for the production of calcium carbide. July 13.

15,525. A. J. Boulton.—From L. H. Freutz. An improved process for the manufacture of hydrogen and carbonic acid or carbonic oxide. July 13.

15,834. A. J. Outheniu Chalandre. Improvements relating to the electrolysis of soluble salts, especially applicable for the production of chlorine. July 17.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

6009. W. McD. Mackey and J. F. Hutcheson. Manufacture of sodic cyanide. July 1.

13,456. W. Raydt. Process for obtaining carbonic acid from gas mixtures in the dry way, and apparatus therefor. July 1.

13,826. C. Dreyfus. Manufacture or production of nitric acid and apparatus therefor. June 24.

13,827. C. Dreyfus. Apparatus for the manufacture or production of hydrochloric acid. June 24.

14,618. H. R. Lewis. The manufacture of ammonium carbonate and acid ammonium carbonate from certain waste or by-products, and apparatus for use in such manufacture. July 15.

14,912. A. J. Holt and G. Millard. Manufacture of bisulphide of carbon and apparatus therefor. July 1.

15,326. A. Wolf and W. S. Blythe. Treatment of galvanisers' flux skimmings. June 24.

15,369. T. L. Willson. Production of calcium carbide. June 24.

15,807. J. W. Stevens. Treatment or utilisation of kelp liquors. July 8.

15,813. F. M. Lyte. Production of chlorine. July 1.

17,066. M. Goldschmidt. Preparation or manufacture of formates and nitrites. July 15.

1896.

6290. D. Penlikoff. See Class X.

9358. —Pictet. Process and apparatus for the production of carbide of calcium. July 8.

VIII.—GLASS, POTTERY, AND ENAMELS.

APPLICATIONS.

13,676. J. B. Vernay. Improvements in machines for manufacturing bottles and other articles of glass. Complete Specification. June 20.

13,823. W. Macrae. Improvements in the production of decorative stained glass or imitations thereof. June 23.

14,901. K. W. R. Goerisch. Manufacture of sulphate glass. July 6.

14,927. T. Hausermann. See Class X.

14,953. H. Propfe. Improvements in the manufacture and production of water-glass with valuable by-products of the said manufacture. July 6.

14,967. J. Wheeler. Improved manufacture of glass suitable for use as a substitute for ground glass and for other purposes. July 6.

15,804. J. Davis and A. J. Davis. Improvements in the method of producing coloured glass lights for lenses, also applicable for other suitable purposes. July 17.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

24,283. F. Albrecht.—From W. Knapp. Process for the production of coloured pictures, writing, or the like on glass, porcelain, enamel, or sheet iron. July 22.

1896.

46. A. Kopp's Sohn. Manufacture of articles of glass. July 1.

11,856. H. Cartledge. Construction of potters' kilns. July 8.

12,923. B. A. Knappett and J. F. Charlesworth. Shading and colouring glass, &c. July 15.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

13,649. R. F. Strong. A new or improved process for the treatment of peat and other ligneous substances for producing paving blocks, slabs, tiles, slates, conduits, and fuel. Complete Specification. June 20.

14,248. T. C. Blanchflower. Improvements in building bricks and the like. June 27.

14,568. J. C. Roberts. The manufacture of an improved plastic compound. July 1.

14,666. M. Volinski. Improvements in the manufacture of briquettes. July 2.

14,673. F. D. T. Lehmann and P. N. Kohlsaat. Improvements in kilns for burning bricks, tiles, lime, and the like. Complete Specification. July 2.

14,828. T. W. Main. Improvements in the manufacture, construction, and arrangement of interlocking reversible sectional paving. July 4.

14,835. A. Van Berkel and J. B. Hamond. Improvements relating to the manufacture of artificial wood and stone for building and other purposes. July 4.

15,316. S. P. Davies.—From G. Frederick. An improved composition for use on streets, roads, pavements, and the like, and on the surfaces of wood and metal. July 10.

15,520. K. Hergenbahn. Process for the preparation of masonry (in marble, granite, syenite, sandstone, and the like) for pillars, pedestals, door and window cases, monuments, and the like, or other objects. Complete Specification. July 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

15,264. H. H. Hoelkin. Improvements in the manufacture of concrete paving slabs, and apparatus therefor. June 24.

1896.

10,841. H. Schneider. Manufacture of paving materials and slabs. June 24.

X.—METALLURGY, MINING, Etc.

APPLICATIONS.

13,163. C. C. Schirm and A. Silbermann. Improved method of producing an even silver ground for underlaying enamel. Complete Specification. June 15.

13,169. B. Mohr. Treatment of sulphide ores for the separation of zinc from the lead and other metals. June 15.

13,187. B. Kleber. Process for the manufacture of weather-proof gypsum, stone, or bricks. Complete Specification. June 15.

13,337. J. David and C. le Donx Glais. A method for the recovery of zinc from slags containing this metal. June 17.

13,371. O. Frölich. Improved process for extracting metals from pyritic ore by the treatment of with chlorine, and for recovering the chlorine employed. June 17.

13,422. C. Sharland.—From L. R. Seammell. An improved process for the treatment of refractory gold and silver ores. June 18.

13,423. C. Sharland.—From L. R. Seammell. An improved process for the treatment of refractory gold and silver ores. June 18.

13,424. C. Sharland.—From L. R. Seammell. An improved process for the treatment of refractory gold and silver ores. June 18.

13,451. L. Pszczolka. Improvements in the Bessemer or Thomas process for the treatment of low qualities of crude iron. June 18.

13,460. J. W. Chenhall. Improvements in the treatment of ores. June 18.

13,476. W. H. Trengrove. Improvements in annealing articles of steel and malleable iron. Complete Specification. June 18.

13,565. J. W. Spencer. Improvements in face-hardening metals. June 19.

13,641. C. F. Claus, jun. Improvements in or relating to the treatment of tin or antimony ores and the separation of the gold and silver contained therein. June 20.

13,756. A. V. Newton.—From A. Nohel. Improvements in metallurgy. June 22.

14,006. C. Parnacott. An improved manufacture of metallic alloy. June 24.

14,222. A. E. Tucker and T. V. Hughes. Improvements in ferro-sodium fluxes. June 26.

14,223. A. E. Tucker and T. V. Hughes. Improvements in and connected with the alloying of metals. June 26.

14,387. H. L. Sulman and H. F. Kirkpatrick-Picard. Improvements in or relating to the extraction of precious metals from their ores. June 29.

14,388. H. L. Sulman and H. F. Kirkpatrick-Picard. Improvements in or relating to the recovery of precious metals from their solutions. June 29.

14,479. A. F. Cothias. Improvements in and in the manufacture of metallic alloys. Complete Specification. June 30.

14,493. J. Garnier. Processes and apparatus for classifying, amalgamating, and cyanising gold and silver ores. Filed June 30. Date applied for May 7, 1896, being date of application in France.

14,622. A. Wolski. Improvements in blast furnaces. July 2.

14,751. P. A. Newton.—From A. Nobel. Improvements in armour plates. July 3.

14,857. H. Pilkington. Improvements in the manufacture of steel. July 4.

14,862. S. Daw. Improvements in the extraction of metals from zinciferous sulphide ores. July 4.

14,927. T. Hausermann. A process for dyeing or ornamenting objects of metal, porcelain, or the like. July 6.

14,957. C. James. An improved process for the reduction of argentiferous and auriferous copper ores, matters, or compounds without loss of the copper, silver, or gold. Complete Specification. July 6.

15,041. L. Doig.—From The Russel and Erwin Manufacturing Co. A method or process of annealing metals. July 7.

15,056. L. de Rigaud. An improved process and apparatus for the extraction of gold and platinum from their ores. July 7.

15,159. C. James. An improved process for the extraction of copper from sulphuretted ores or compounds. Complete Specification. July 8.

15,385. D. Colville, jun. Improvements in the manufacture of composite armour plates. July 11.

15,523. T. D. Nicholls. Improvements in converters for treatment of copper matte or other materials by the Bessemerising process. July 13.

15,542. W. H. Howard. Improvements in and relating to the desilverisation of lead bullion. Complete Specification. July 14.

15,612. J. Pourtales.—From W. Strieby and S. Crosdale. Improvements in the precipitation of precious metals from solution. July 14.

15,685. W. Muir, H. W. Handcock, and A. H. Dykes. Improvements in extracting gold from ores or materials containing it. July 15.

15,699. G. Duceau. New metallic alloy. July 15.

15,707. B. H. Thwaite. Improvements in the production of hardened surfaces and in the hardening of steel armour or other plates. July 16.

15,749. O. Inray.—From E. F. Turner. An improved regenerative process for the treatment of sulphide ores. July 16.

15,833. J. P. van der Ploeg. Improvements in or relating to the extraction of gold from ores and other compounds, the recovery of gold extracted from the treated ores, &c., and the recovery of the chemicals used in the process. July 17.

15,946. J. A. Mays. Process for reducing lead. July 18.

15,947. J. A. Mays. Process of and apparatus for reducing and separating metals from zinc and lead ores. July 18.

15,965. R. H. Peak. Improvements in process of converting ferric oxide into magnetic oxide of iron. Complete Specification. July 18.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

12,692. A. J. Boulton.—From P. A. Gasse. Treatment of refractory ores. July 1.

13,534. E. A. Ashcroft. Treatment of zinc-bearing ores and zinc-bearing products. July 15.

13,858. A. J. Boulton.—From T. Prioux, C. Prioux, and C. Hugot. Improvements in or relating to soldering metals. July 22.

14,162. E. G. Appleby.—From L. F. Gowans. Treatment of ores and the like by the cyanide process, and in appliances therefor. July 1.

15,426. S. Taylor. A new or improved manufacture of compound metallic plates, sheets, and strips for various purposes. July 8.

15,656. W. H. James. Process for the extraction of precious metals from their ores and compounds. June 24.

15,954. W. P. Thompson.—From La Société pour l'extraction integrale et economique de l'or, Procédé de Rigaud. Gold-extracting processes and apparatus therefor. July 1.

17,256. R. Lewis. Finishing tin andterne plates. July 22.

23,950. C. Parnacott. Manufacture of metallic alloys. July 15.

1896.

6290. D. Peniakoff. A process for the production of double aluminium sulphides (or sulphurets) with alkaline metals or metals of (the nature of) alkaline earths. June 24.

10,997. J. Jones. An improved method or process for the treatment of gold-bearing antimony ores. July 1.

13,476. W. H. Trengrove. Improvements in annealing articles of steel and malleable iron. July 22.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

13,200. A. G. Stromberg. Improvements in or applicable to the charging of accumulators. June 15.

13,407. C. Kellner. Improvements in electrolytic apparatus. June 17.

13,520. C. Pollak. Improvements in plates for accumulators or secondary batteries. Complete Specification. June 18.

13,521. P. Jensen.—From H. Cappelen and D. Cappelen. Improvements in the manufacture of carbon anodes for electrolytical processes. Complete Specification. June 18.

13,646. W. H. Smith and W. Willis. Improvements relating to electric accumulators or storage batteries, and to the manufacture of plates or electrodes therefor. June 20.

13,688. A. E. Bonna, A. Le Royer, and P. van Berchem. Improved electrical apparatus for the treatment of air, gases, and vapours. June 20.

13,689. A. E. Bonna, A. Le Royer, and P. van Berchem. Improved electrical apparatus for the treatment of air, gases, and vapours. June 20.

13,690. A. Le Royer, A. E. Bonna, and P. van Berchem. Improvements in electrolytic apparatus. June 20.

14,367. C. A. Hales. An improvement in electro-deposition of metals and metallic alloys. June 29.

14,393. P. Jensen.—From H. C. F. Stormer. Improvements in anodes for electrolytic purposes. June 29.

15,129. F. W. Golby.—From O. Arit. A process and apparatus for effecting electrolysis. Complete Specification. July 8.

15,433. H. Weymersch and A. McK. Cardwell. An improved preparation of electrolyte for use in semi-dry primary or secondary electric batteries. July 11.

15,517. R. Sauerwald and H. Grüne. Improvements in electric batteries. July 13.

15,696. E. Casper. Improvements in the manufacture of tubes by electro-deposition. July 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

14,902. G. Fabbro. Plates for secondary batteries. June 24.

16,736. J. Pfleger. Apparatus for extracting gold and silver from cyanide solutions by electricity. June 24.

- 16,737. J. Pileger. Electrical apparatus for extracting gold and silver from cyanide solutions. July 1.
17,821. F. King. Secondary batteries. May 27.

1896.

- 13,079. W. P. Thompson.—From C. C. Lesenberg. Dry batteries. July 22.
13,521. P. Jensen.—From H. Cappelen and D. Cappelen. Improvements in the manufacture of carbon anodes for electrolytical processes. July 22.

XII.—FATS, OILS, AND SOAP.

APPLICATIONS.

- 13,353. R. T. Cardell. Laurel cream soap or any combination of laurel in toilet requisites or soaps, cold creams, &c., &c. June 17.
13,726. J. Mendess. Liquid soap. June 22.
14,056. B. J. Hicks and E. F. Bach. An improved lubricating composition. June 25.
14,198. J. Lightfoot. Improvements in the manufacture of dry soap. June 26.
14,308. A. Schuehardt and T. Otto. New washing substance and process for making it. Complete Specification. June 27.
14,806. T. McKinnon. Improvements in or relating to soaps or other like preparations. July 4.
15,050. G. C. Dymond.—From G. F. Metzger. Improvements in or appertaining to separating oil from its volatile solvent. Complete Specification. July 7.
15,336. T. Coad. Improved treatment of fat or fatty waste. July 10.
15,548. J. H. Tearle. Waste soap utiliser. July 14.
15,597. G. C. Dymond.—From G. F. Metzger. A new or improved process of and apparatus for separating naphtha or other volatile solvent from oil. Complete Specification. July 14.
15,938. W. Downs. A new or improved manufacture of soap. July 18.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

- 13,623. A. G. C. Dymond. From The Kobero Eisenwerke. Improvements in or appertaining to oil presses. July 8.

1896.

- 10,681. J. Ascough. Manufacture of soaps and saponaceous compounds. July 15.
10,837. J. Glatz and O. Lugo. Production of glycerine and caustic soda from soap lyes. July 22.
12,953. H. W. Wilson. An improved soap or cleansing agent. July 22.

XIII.—PAINTS, PIGMENTS, VARNISHES,
RESINS, INDIA-RUBBER, Etc.

APPLICATIONS.

- 13,238. K. A. Frosell. Improvements in the manufacture of waterproofing solutions. June 16.
13,886. W. P. Tatham and W. Tatham. Improvements in the manufacture of white lead. Complete Specification. June 23.
14,267. D. Mareus. Improvements in paints and varnishes. June 27.
14,428. H. C. Webster and R. Crawford. Improvements in the manufacture of white lead. June 30.
14,613. C. Day. An improved liquid varnish gum. July 2.
14,884. W. Mitchell.—From G. L. Ball. A liquid for removing varnish. July 6.

- 14,988. A. B. Browne. Improvements in the manufacture of white lead. Complete Specification. July 7.

15,165. T. Worth, J. Foster, and H. C. P. Graves. A new or improved compound for use as a substitute for india-rubber, leather, or other substances, or for any other purposes to which it may be applicable. July 8.

15,689. J. W. Steiger and P. D. McArthur. Improvements in stick sealing-wax. Complete Specification. July 15.

15,692. F. J. Longton. A new or improved article of manufacture applicable for use as a substitute for india-rubber. July 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

- 13,973. S. B. Schryver. Manufacture of paints and pigments. July 22.
17,025. H. C. Longsdon. Improved mechanism for pressing and rolling plastic substances, the same being specially applicable for use in the treatment of crude india-rubber. July 22.

1896.

6396. K. Thou. Blacking for leather and the like. June 24.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATIONS.

- 13,281. W. L. Wise.—From Knoll and Co. Improvements in the manufacture or production of an albumen-tannin compound. June 16.
13,526. G. W. Adler. Improvements in the tawing of hides and skins. June 19.
13,686. H. Schmidt and J. Laudini. Arrangement for performing a continuous work of tanning. June 20.
13,906. F. C. W. Webb. Improvements in machinery or apparatus for use in tanning hides and skins. June 23.
14,293. G. W. Adler. An improved process of and compound for tawing hides and skins. June 27.
14,548. V. Quaedvlieg. Process for rapidly opening the hair cells of raw hides for the purpose of removing the hair therefrom. July 1.
14,617. W. Sagar, senr., A. P. Sagar, and W. Sagar, junr. Improvements in the method of and apparatus for removing grease or fatty matter from skins and other leather and the like. July 2.
15,044. F. E. Burlingame. Improvements in the manufacture of leather. Complete Specification. July 7.
15,165. T. Worth, J. Foster, and H. C. P. Graves. See Class XIII.

COMPLETE SPECIFICATIONS ACCEPTED.

1896.

- 10,752. G. E. Wright and W. Monk. Method and apparatus for degreasing leather. June 24.
11,695. K. Moller. Process for hardening chrome-dressed leather. July 8.

XV.—AGRICULTURE AND MANURES, Etc.

APPLICATION.

- 15,173. E. Paternotte. Improvements in chemical manure mixers and the like. Complete Specification. July 13.

XVI.—SUGARS, STARCHES, GUMS, Etc.

APPLICATIONS.

- 15,485. A. Rohrbach. A new or improved process for purifying centrifugally separated substances. Complete Specification. July 13.
15,575. C. Wahl. An improved method of purifying starch and like products. July 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1896.

5844. J. Kantorowicz. An improved process for preparing soluble starch. July 1.
 11,976. J. Werner. Machines for mixing syrup. July 22.
 11,977. J. Werner. Machines for cooling syrups. July 8.
 12,447. A. J. Boulé.—From C. M. Higgins. Flour and starch pastes, and processes of making same. July 15.

XVII.—BREWING, WINES, SPIRITS, ETC.

APPLICATIONS.

13,132. S. H. Wright. An improved method of dealing with yeast in the process of fermentation, of first reducing it in bulk, and cleansing it from carbonic acid gas and other foreign matters, gaseous or otherwise, the products of fermentation or otherwise; and second, of promoting the further development of the yeast so treated; and apparatus therefor. June 15.

13,262. B. W. Valentin. Manufacture of material for use in brewing or priming ales and beers. June 15.

13,695. S. H. Wright. An improved method of dealing with yeast in the process of fermentation, of first reducing it in bulk, and of cleansing it from carbonic acid gas and other foreign matters, gaseous or otherwise, the products of fermentation or otherwise; and second, of delivering the gaseous products and other products, if required, in separate receptacles; and apparatus employed in the above process. June 22.

14,501. A. Moller. Improvements relating to the manufacture of sparkling wine and apparatus therefor. Complete Specification. June 30.

15,805. C. C. Doig. Process for evaporating the liquid ingredients of the residual products of distilleries and other manufactories and sewage, but particularly the residual products of distilleries known as burnt ale. July 17.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

7258. J. C. R. G. Boulet. Manufacture of fermented products. July 15.

14,482. V. Lapp. Method and apparatus for treating mash in brewing for obtaining the wort therefrom. July 8.

1896.

2684. B. Rothenbucher. Apparatus for producing crushed malt and a process of producing wort from the said malt. June 24.

XVIII.—FOODS, SANITATION, ETC., AND DISINFECTANTS.

APPLICATIONS.

A.—Foods.

13,703. J. J. Hazard. Improvements in the preservation of organic matters and in apparatus for use in connection therewith. June 22.

14,196. G. C. Dymond.—From G. H. Walker, G. E. Gordon, and J. H. Waterhouse. Improvement in or relating to the treatment of milk for the purpose of suiting it to individual digestions. Complete Specification. June 26.

14,209. R. G. Nash. Improvements in the aëration and preservation of milk and apparatus therefor. June 26.

14,581. C. L. Bachelierie. Improved process of preserving organic substances, more particularly applicable for elementary substances. Complete Specification. July 1.

14,644. A. J. Boulé.—From R. Emmerich. A new or improved process for preserving carcasses of animals or parts thereof. July 2.

B.—Sanitation.

14,124. A. Angell and F. Candy. Improved preparations for use as precipitants in the treatment of sewage and other polluted water. June 25.

14,125. A. Angell and F. Candy. Improvements in the manufacture of materials for use in the filtration and purification of impure water and other liquids. June 25.

14,565. R. W. Cass. Improvements in or relating to means or apparatus for removing or taking out suspended matter in sewage and trade refuse. July 1.

14,638. J. Corp. Improvements in the treatment of smoke and fumes from furnaces. July 2.

15,208. H. W. Kearns. Improvements in and apparatus or means for treating the sludge or deposit from foul waters and the like. July 9.

15,456. E. Sergeant. Combined apparatus for burning refuse and disinfecting. July 13.

15,611. W. G. Waterman.—From L. Alers-Hankey. Improvements in apparatus for purifying water. Complete Specification. July 14.

C.—Disinfectants.

14,634. J. B. Koenig. A process for the manufacture of a preservative liquid which possesses at the same time disinfecting and disodorific qualities. July 2.

14,852. M. Crawford. Improvements in the manufacture of disinfecting, deodorising, and bleaching agents, and in apparatus therefor. July 4.

COMPLETE SPECIFICATIONS ACCEPTED.

A.—Foods.

1895.

15,506. A. J. Boulé.—From A. Delcroix. Coffee or coffee substitutes. July 8.

26,219. C. G. Moor. Humanised condensed milk. July 22.

1896.

2081. W. F. Maclaren and A. S. Fleming. Manufacture of condensed milk products. June 24.

8194. J. C. Uhlenbrock. Method and apparatus for the manufacture of margarine or butter substitute. July 8.

12,150. F. O. Jacob. Process for preserving solid organic alimentary substances. July 22.

B.—Sanitation.

1895.

16,308. N. V. Sleen and A. Schneller. Apparatus for the sterilisation and purification of water. July 8.

C.—Disinfectants.

1895.

23,581. J. Reepmaker. A composition for protecting men and animals from the attacks of mosquitoes and other insects. June 24.

1896.

9345. J. Ascough. Manufacture of antiseptic preparations for the preservation of animal and other food-stuffs. June 24.

11,557. S. Pitt.—From The Société Anonyme de l'Institut R. Pietet. Process and apparatus for producing gaseous mixtures, mainly formic aldehyde, for disinfecting purposes. July 15.

XIX.—PAPER, PASTEBOARD, ETC.

APPLICATIONS.

13,242. W. Hunkemoller. Process for manufacturing artificial whalebone. Complete Specification. June 16.

15,519. G. L. T. Hartmann. Improvements in machines for the manufacture of millboard, pasteboard, or the like. Complete Specification. July 13.

15,552. J. Tait. Improvements in bleaching and purifying paper pulp. July 11.

COMPLETE SPECIFICATION ACCEPTED.

1896.

11,961. T. C. Cadogan and The O. S. Kelly Co. Improvements in devices for handling and feeding paper stock. July 22.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

APPLICATIONS.

14,552. O. Inray.—From The Fabriques de Produits Chimiques de Thann et de Mulhouse. Improvements in the manufacture of artificial musk. July 1.

14,928. H. Inray.—From Harmann and Reimer. Process for the manufacture of vanilline from isoeugenol and eugenol. July 6.

14,954. C. Goldschmidt. The preparation of a condensation product from vanilline and para-phenetidine. July 6.

15,295. W. E. Heys.—From The Chemische Fabrik vormals Sandoz. The manufacture or production of bismuthoxy-iodide-methyl-gallate. July 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

14,631. A. M. Parker. Manufacture of germ extract. July 8.

17,351. W. Schmidt. A process for the preparation of cauphor in the condition of powder. July 8.

17,417. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. The manufacture or production of pharmaceutical compounds. July 22.

1896.

3192. G. H. R. Dabbs. Apparatus for the production of extracts of tea or other matters. July 15.

11,166. J. C. Mewburn.—From the Chemische Fabrik von Heyden Gesellschaft mit beschränkter Haftung. A new perfume or odiferous principle and process for the manufacture of same. July 1.

XXI.—PHOTOGRAPHY.

APPLICATIONS.

14,977. H. Fowler. A process for producing photographs in gold, silver, or other metals on polished surfaces. June 25.

15,852. E. P. Schoenfelder and E. Kehl. Improvements in chemical compositions for preparing the surface of suitable material for photographic prints. July 17.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

16,548. F. W. Lauchester. Photography in colours. July 8.

1896.

11,306. J. Hauff. Photographic developing solutions. July 15.

12,645. J. W. McDonough. Colour photography. July 15.

XXII.—EXPLOSIVES, MATCHES, Etc.

APPLICATIONS.

13,152. M. I. E. Morris. Improvements in explosives. June 15.

13,269. L. Kelbetz. Improvements in the manufacture and production of explosives. Complete Specification. June 16.

13,270. L. Kelbetz. Improvements in the manufacture and production of explosives. Complete Specification. June 16.

13,755. A. V. Newton.—From A. Nobel. Improvements in rockets. June 22.

13,922. G. Bencke. Improved manufacture of explosives. June 24.

14,007. F. M. Hale and J. B. Reavil. Improvements in percussion fuses for explosive projectiles or shells. June 24.

14,320. C. Lann.—From A. Yernander. An improved safety fuse or quick-match. June 29.

14,595. A. Scott. Improvements in matches. July 1.

14,950. S. V. Dardier. Improvements in the manufacture of explosives. July 6.

15,022. G. B. Ellis.—From La Société Chimique des Usines du Rhône anciennement G. P. Monnet et Cartier. Improvements in the manufacture of explosive compounds. July 7.

15,351. A. F. Hargreaves. Improvements in explosives. July 10.

15,977. L. L. Billaudot. An improved process of manufacturing phosphorus. July 18.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

23,443. G. G. Andre and C. H. Curtis. Manufacture of explosives. June 24.

1896.

6,555. R. Pierre and W. Pottgiesser. Manufacture of safety explosives. July 8.

13,269. L. Kelbetz. Improvements in the manufacture and production of explosives. July 22.

13,270. L. Kelbetz. Improvements in the manufacture and production of explosives. July 22.

PATENT UNCLASSIFIABLE.

COMPLETE SPECIFICATION ACCEPTED.

1895.

25,013. W. L. Woods. An improved plastic composition and process of combining the same. July 1.

.....

THE JOURNAL OF THE Society of Chemical Industry:

A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 8.—VOL. XV.]

AUGUST 31, 1896.

[Non-Members 30/- per annum; Members
21/- per Set of extra or back numbers;
Single Copies (Members only) 2/6.]

The Society of Chemical Industry.

Past Presidents:

Sir H. E. Roscoe, LL.D., V.P.R.S.	1881—1883.
Sir Frederick Abel, Bart., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
Dr. W. H. Perkin, F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Prof. James Dewar, F.R.S.	1887—1888.
Ludwig Mond, F.R.S.	1888—1889.
Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
E. Rider Cook	1890—1891.
Prof. J. Emerson Reynolds, M.D., D.Sc., F.R.S.	1891—1892.
Sir John Evans, K.C.B., F.R.S.	1892—1893.
E. C. C. Stanford	1893—1894.
Dr. T. E. Thorpe, LL.D., F.R.S.	1894—1895.
Thomas Tyrer	1895—1896.

COUNCIL FOR YEAR ENDING JULY, 1897.

President: Dr. Edward Schunck, F.R.S.

Vice-Presidents:

Chas. Dreyfus.	A. Gordon Salamon.
Dr. A. Dupré, F.R.S.	E. C. C. Stanford.
Prof. A. K. Huntington.	G. N. Stoker.
A. H. Mason.	Dr. T. E. Thorpe, F.R.S.
Boverton Redwood.	Prof. W. A. Tilden, F.R.S.
Sir H. E. Roscoe, F.R.S.	Thomas Tyrer.

Ordinary Members of Council:

George Beilby.	C. C. Hutchinson.
R. Forbes Carpenter.	Ivan Levinstein.
R. Le Neve Foster.	J. S. McArthur.
Oscar Guttman.	B. E. R. Newlands.
Douglas Herman.	Sir Robert Pullar.
David Howard.	Wm. Thorp, B.Sc.

With the Chairmen and Secretaries of Sections.

Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

Honorary Foreign Secretary:

Ludwig Mond, F.R.S.

General Secretary: Charles G. Cresswell.

Offices: Palace Chambers, 9, Bridge Street, Westminster, S.W.

THE JOURNAL.

Publication Committee:

The President.

A. H. Allen.	Wm. Kellner, Ph.D.
G. H. Bailey, D.Sc., Ph.D.	J. Lewkowitsch, Ph.D.
Joseph Bernays, M.I.C.E.	A. R. Ling.
H. Brunner.	Ludwig Mond, F.R.S.
A. C. Claudet.	B. E. R. Newlands.
E. Rider Cook.	John Pattinson.
Chas. Dreyfus.	W. H. Perkin, Ph.D., F.R.S.
Sir John Evans, K.C.B., F.R.S.	H. R. Procter.
John Heron.	Boverton Redwood.
D. B. Hewitt, M.D.	Walter F. Reid.
David Howard.	John Spiller.
Prof. J. J. Hummel.	William Thorp.
Prof. A. K. Huntington.	Thomas Tyrer.
F. Hurter, Ph.D.	Lewis T. Wright.
C. Clarke Hutchinson.	

Editor:

Watson Smith, 34, Upper Park Road, Haverstock Hill, N.W.

Assisted by the following Staff of Abstractors:

NOTICES.

COLLECTIVE INDEX.

A collective index, embracing the whole Journal from the Proceedings of the First Annual General Meeting, 1881, to the close of 1895, is now in preparation, and will be ready about the end of the current year. It will contain both a subject-matter and authors' names portion and will be a volume of about 500 pages, uniform in size with the Journal. The prices will be as follows:—

To Members (see Rules 25 and 27) who make application with remittance not later than September 30, 1896	Each Copy	5s.
To Members (see Rules 25 and 27) who make later application; Libraries, Corporations, and Exchanges on the Society's List, and Past Members (see Rule 30)	Each copy	10s.
To Subscribers		12s. 6d.
To others		15s.

a spiral plate I, P, the outer edge of which has a flange *i*, and accumulates on the surface at F, until it passes through the filter K into the perforated cylinder J, and finally out through *f*.—R. B. P.

[*Smoke, &c. Purification*], *Impts. in Machinery applicable for Filtering, Condensing, and Absorbing Air, Smoke, Fumes, and other Gases, or for Cooling or Heating Water or other Liquids.* H. R. Chubb, Greenwich, Kent. Eng. Pat. 14,456, July 30, 1895.

In addition to the objects mentioned in the title, the apparatus may be used for impregnating alkaline, acid, or neutral solutions with waste or other gases.

It consists mainly of two chambers, into the first of which the gas or smoke to be treated is forced by means of a fan. Inside this chamber a whirling device causes the gas to impinge against a series of baffle plates which intercept and retain particles of impurities. In the second chamber there is a slowly rotating hollow drum, filled with a suitable filtering material, into which the gas from the first chamber is fed. The gas then passes through the filtering medium and the perforated walls of the drum into the second chamber. In the lower part of this is a layer of liquid, the nature of which depends upon the gas under treatment. Resting on the drum is an endless band with buckets attached to it, the lower end of which hangs in the layer of liquid. As the drum rotates it carries with it the band and its buckets. The latter carry up the liquid and discharge it on to the upper part of the drum, thus keeping the filtering material drenched. The liquid as it runs off is caught in a trough and carried away to suitable appliances—filters, crystallising pans, &c.—for treating it. The purified gas is removed from the top of the second chamber by means of a fan.—R. B. P.

Evaporating and Distilling Liquids, Impts. in Apparatus for. E. Theisen, Baden-Baden, Germany. Eng. Pat. 14,852, Aug. 6, 1895.

THE apparatus consists of a hollow drum *a*, closed by end-plates, *o o'*. It is supported at one end by an axle *b* and at the other by a hollow axle *c*, through which passes the pipe *d e*. This pipe serves for feeding the liquid to be evaporated on to the inner surface of *a*. The centrifugal action set up by rotating the drum causes the liquid to distribute itself in a thin uniform layer on the inner surface of the drum, and also to flow along it and into the annular

lute *l* at the other end, from which it is removed by a stationary scoop at the end of the pipe *h*. At the other

end of *h* is a cock *k*, by means of which the liquid can be run off, or again passed into the drum through *d* and the cock *i*. Fresh liquid also can be introduced through the latter. Heat is applied to the exterior of the drum by the furnace *g, f, f'*, to effect the evaporation of the liquid on the interior surface. The lute *l* is divided by a flat ring *n*, and being filled with a suitable fluid, forms, with the fixed plate *m*, a seal which prevents the products of distillation from escaping from the drum except by the outlet *p*. Two or more concentric drums may be used. Various modifications of the apparatus are described.—R. B. P.

Pulverulent, Granular, or Fibrous Material's, Apparatus for Drying. E. Theisen, Baden-Baden, Germany. Eng. Pat. 14,853, Aug. 6, 1895.

ON to the interior surface of a revolving drum the outer surface of which is subjected to heat, the material to be dried is fed in such a manner that it is spread into a uniform thin layer by centrifugal force. A series of scrapers set at certain points, stir up the material and deliver it on to a fresh portion of the drum's inner surface, and at the same time cause it to travel along the drum towards the discharge orifice.—R. B. P.

[*Muffle*] *Gas Furnaces for Enamelling, Assaying, Hardening, Tempering, Melting, and the like, An Impt. in the Construction of.* F. Willis, London. Eng. Pat. 14,971, Aug. 8, 1895.

THE improvement consists in surrounding the muffle with an additional muffle in order that the products of combustion

may be caused to circulate in the manner indicated by the arrows in the figure, which represents a vertical section through the muffle furnace.—A. G. B.

II.—FUEL, GAS, AND LIGHT.

Sulphite Liquor from Wood Pulp, Utilisation of [Fuel]. Papier Zeit. 1896, 21, [37], 1183.

THE author describes a method that was adopted in 1890 for the manufacture of briquettes from small coal and concentrated waste sulphite liquors. The experiments were conducted at the iron-smelting furnaces at Komitat Gömör, in Hungary. The waste sulphite liquors were obtained from a pulp mill in the vicinity, and then concentrated to a suitable consistency in a series of open tanks. Leated by the waste gases from the furnaces. The thick syrup-like residue was mixed with the coal dust in the briquette-making machine. The briquettes when dried, were hard, and formed an excellent fuel, giving off practically no sulphurous odour when burnt. It was also found that by using sufficient lime flux, practically the whole of the sulphur went into the slag when employed in the smelting furnace. After overcoming a number of difficulties, the manager of the works writes, under date of April 30th of the present year, to the effect that the manufacture of these briquettes is carried on satisfactorily, and they not only form good fuel upon ordinary grates, but also in the smelting furnace.

—S. P. E.

Gas Processes, and particularly the Management of Furnaces, Apparatus for Controlling. W. Hempel. Chem. Ind. 1896, **19**, 98—101.

THE author proposes to utilise the known fact that the form of a flame is altered by a change in the composition of the atmosphere surrounding it, to obtain a test apparatus showing at a glance any change in the composition of the chimney gases in furnaces and other analogous cases.

In the accompanying illustration, B is a tube leading from the furnace flue, preferably close behind the bridge, or before the furnace gases have passed through any considerable length of brick flue. A is a tube leading into the

chimney beyond the damper. D is a graduated glass cylinder, open top and bottom, and connected to A and B by the elbow-pieces E and C. G is a narrow tube connected by the flexible tube L to the gas supply, held in position by the air-tight stopper m, and having its nozzle flush with the lowest graduation mark of D. i and h are rosette ventilators. The tube G is removed, the gas lighted, and the tube replaced, and with i and h fully open the gas flame is regulated to a definite height. The firing of the furnace is then arranged so as to give the maximum of carbonic anhydride—by nearly closing the air supply—and ventilator i being quite closed, h is gradually closed till the flame is just extinguished, when the position of h is marked. At the same time a sample of the furnace gas is drawn by means of k and analysed. The furnace is then brought to its most advantageous condition, the ventilators h and i are again opened, the gas re-lighted, i closed, and h closed nearly to the mark previously made, and re-marked; the height of the flame is then noticed, and a sample of the furnace gas taken at K and analysed. By a few trials an empirical scale can be drawn up, showing from the height of the flame the percentage of carbonic anhydride in the furnace gases. F is a Kretz pressure gauge in connection with the apparatus by the lead tube n. This consists of the pipette P full of water in a cylinder of the same and dipping into a layer of a liquid just heavy enough to sink in water—such as a heavy petroleum to which a little carbon bisulphide has been added. This forms a delicate pressure gauge, as a very slight change of level in the bulb of the pipette is represented by a very considerable change in level of the lower layer of liquid in the pipette tube. The pressure in the apparatus is adjusted to that of the atmosphere before reading the flame height, by slightly opening ventilator i.

Very good results have been obtained by this apparatus, which can also be applied to testing other than furnace

gases—such as chlorine generators, sulphuric acid chambers, &c. Where coal-gas is not available, hydrogen, water-gas, or candles can be employed. In the case of the candle, however, it must be remembered that restriction of the oxygen means diminished flame, and not, as in the case of gas flame, increased length, and the variation is much less. For a candle, the form of the apparatus must of course be slightly modified.—L. T. T.

Emission of Light. H. Krüss. Journal für Gasbeleuchtung, 1896, **39**, 425—427.

THE results are given of researches made by Lummer, Kurlbaum, and Wien at the Reichsanstalt on a suitable standard or unit of light-emission, and also of experiments by St. John on the emissive powers of substances. Experiments with Violle's platinum unit and Siemens' modification of it have shown that methods depending upon the melting point or solidifying point of platinum are not satisfactory. Lummer and Kurlbaum adopt as their unit the amount of light emitted from 1 sq. cm. of glowing platinum-foil at a fixed temperature. The foil used is of pure platinum, 25 mm. broad, 60 mm. long, and 0.015 mm. thick, and is heated by passing through it a current from a secondary battery. In front of it is placed a suitable diaphragm with an aperture of 1 sq. cm. The temperature is fixed by a peculiar and interesting absorption method. The absorption vessel consists of a cylindrical glass ring closed by two quartz plates, 1 mm. thick, and containing a layer of water 2 cm. thick. The proportion of the total radiation transmitted through such a vessel depends upon the quality of the radiation, and hence depends upon the temperature of the radiating surface. The normal temperature is fixed as being such that the proportion of the total radiation transmitted shall be one-tenth. The radiation is measured and the proportion determined by means of a bolometer. As far as this element is concerned, the unit can be fixed to an accuracy of 0.3 per cent., or, taking all sources of error into account, to an accuracy of 1 per cent.

St. John has compared the brightness of a hot platinum surface with that of a part of the same platinum at the same temperature but coated with a metallic oxide. The platinum-foil was enclosed in a furnace at a temperature of 1,100—1,200° C., and the observations were made through a hole in the wall of the furnace by a spectro-photometer. Taking the brightness of the plain platinum-foil for a given wave-length ($\lambda = 0.540$) as unity, that of the other surfaces was only found to vary from 0.787 in the case of didymium oxide to 1.017 in the case of lanthanum oxide. Within such a closed hot space the brightness does not measure the emissive power, for the radiation is the sum of the energy emitted and reflected from the surface; and the results are in entire accordance with Kirchhoff's law, according to which the sum of these in any given direction should be constant for all surfaces and equal to that from a perfectly black surface. Unfortunately, St. John has not examined the behaviour of thorium oxide, which is used in the Auer burner. But the fact that the rare earths investigated behave in accordance with Kirchhoff's law is fatal to the suggestion which has often been made that they have a specific luminosity or power of emitting, in the form of light, a part of the energy absorbed in their formation. The observed gradual decrease of efficiency of the Auer burner must be ascribed simply to a gradual contraction of the mantle or of its active surface, and not to any supposed diminution of its specific luminosity. The measurement of brightness above described can be converted into a method of measuring emissive power by pushing a hot (but not glowing) porcelain tube through the walls of the furnace close up to the platinum plate and observing through this tube; we thus cut off reflected light and only observe that directly emitted. Taking the emissive power of platinum as unity, that of lanthanum oxide is found to be 2.15, and that of zirconium oxide as high as 3.15.—D. E. J.

Rare Earths. O. N. Witt. Chem. Ind. 1896, **19**, 156.

THE thoria required for incandescent mantles is now obtained from monazite, which contains only 4—8 per cent. of the earth. After separation of thoria, the ceria, didymia, and lanthana, which make up 50 per cent. of North

Carolina monazite, are found in the same residue, without other admixture. In the present paper, the separation of ceria and attempts to utilise it are described; didymia and lanthana will be dealt with in a subsequent communication. To the mixture of the chlorides of the three metals caustic potash is added till alkaline (caustic soda must not be used, since NaCl dissolves CeO_2) and chlorine passed into the mixture warmed on the water-bath. When the gas is no longer absorbed, a portion is filtered and tested for cerium by ammonia and hydrogen peroxide; if the metal be found, the treatment with potash and chlorine is repeated. The yellow dioxide is filtered off, washed with 5 per cent. potassium chloride, and its hydrochloric acid solution examined for the absorption bands of didymium; if this metal be absent, the solution is also assumed to be free from lanthanum, and pure cerium oxalate is precipitated on addition of oxalic acid. If the didymium bands are seen, the chlorine treatment must be repeated.

Cerium oxalate finds a limited application in medicine, but on account of its insolubility is not suitable for general technical purposes. The most convenient salt is the double sodium cerium nitrate obtained by dissolving 36 grms. of cerium oxalate in 250 c.c. of nitric acid (equal parts acid of sp. gr. 1.4 and water), boiling until nitrous fumes are no longer evolved, and adding 21 grms. of anhydrous sodium carbonate. On cooling, almost the whole of the double salt crystallises out; it is unaltered by air.

1 per cent. of cerium dioxide imparts a fine yellow colour, which resists a white heat, to a glass of a composition suitable for an earthenware glaze, but when used as glaze, only a useless pale yellow colour was produced. Porcelain could not be coloured by cerium compounds. The double nitrate has no effect on the production of aniline blacks; earlier statements to the contrary must have been based upon results obtained with cerium salts containing impurities, possibly vanadium. On the other hand, cerium forms a mordant for the alizarin colours. One method is to print the sodium cerium nitrate, thickened in a suitable manner, on the fabric, dry, and pass through boiling soda; this precipitates insoluble sodium cerium carbonate in the pores of the material. The colours produced on material mordanted in this way are tolerably fast to soap; the shades are intermediate between those given by chromium and iron mordants.—A. C. W.

Denaturing Alcohol [Alcohol Incandescent Lamps].

G. Jacquemin. *Comptes rend.* **122**, [25], 1502.

THE author proposes to denature alcohol for use in incandescent lighting by the use of the trihydrate of ethyl hydrosulphide obtained by the distillation of sulphovinate and sulphide of barium, and mixed with 9 per cent. of ethyl hydrosulphide. 5 grms. of this substance will suffice to denature a hectolitre of 90° alcohol at a cost of 15 centimes, and whilst incapable of precipitation or removal by fractional distillation, does not affect the burning of the spirit, the trace of sulphur present being infinitesimal.—C. S.

Incandescent [Alcohol] Spirit-Light, in comparison with other Sources of Light. F. Fischer. *Zeits. angew. Chem.* 1896, 433—434.

THE author describes a wickless spirit-lamp [alcohol-lamp] by means of which an ordinary mantle can be raised to incandescence. In the accompanying figure the spirit is poured into the annular reservoir A (the screw-cap *a* being removed), falls through the side tubes into B, and then rises in the central tube. The cock *b* allows spirit to be poured at will into the little capsule *c* surrounding the central tube; this, when lighted, vaporises the spirit in the central tube, and the vapour is driven out at *n* into a Bunsen burner on which is hung the mantle C. Spirit of not less than 93 per cent. should be used; of this the lamp uses 97 c.c. per hour, and gives a steady pleasant light of 42 candles with a new mantle, sinking to 36 candles after 60 hours' use. Taking as average costs, spirit, 32 pf. per litre (1s. 6d. per gallon); petroleum, 22 pf., "Kaiseröl," 42 pf. (1s., 1s. 11d.); stearin candles, 150 pf. per kilo. (8d. per lb.); coal-gas, 16 pf. per cb. m. (1s. 6d. per 1,000 cb. ft.); and the wear of mantles at 0.5 pf. per 100 candle-hours, the author gives from his own and earlier researches (*Zeits. angew. Chem.* 1891, 623, and 1895, 634 and 665) a comparative table of which the following is a condensation:—

	Actual Light.	Cost per Hour.	Calculated to 100 Candle-Hours.					Radiant Heat per Minute, on Surface of 100 Sq. Cm. at 37.5 Cm. Distance, for every 1 S. Candle-Power.
			Consumption.	Cost.	CO ₂ produced.	H ₂ O produced.	Heat evolved.	
Candles		Pf.	Grms.	Pf.	Kilo.	Kilo.		
Stearin	1	1.3	920	130.0	1.18	1.04	8,100	8.7

—J. T. D.

Hydrocarbons produced by the Action of Water on Metallic Carbides. H. Moissan. *Comptes rend.* **122**, [25], 1462—1467.

IN view of the fact that aluminium carbide gives off pure methane under the action of water, and that uranium carbide furnishes under the same treatment, in addition to

gaseous products, liquid and solid hydrocarbons (4 kilos. of carbide yielded over 100 grms. of liquid hydrocarbons), chiefly of the ethylene series, associated with smaller quantities of the acetylene series and saturated hydrocarbons,—it is considered that the protracted evolution of methane in certain places may be due to the first-named reaction, and that the occurrence of the second reaction at high temperatures might give rise to saturated hydrocarbons analogous to petroleum. To show that petroleum is not always attributable to an animal or vegetable origin the asphalt found in the fissures of the fresh-water limestone of Limagne is cited, the said asphalt being in direct relation with veins of basaltic tuff, and therefore with volcanic phenomena. The petroleum found at a depth of 1,200 metres at Riom may be ascribed to the action of water on carbides, and the escape of carbon dioxide from the granite rocks bordering the tertiary formation near Saint-Nectaire may be an oxidation product of hydrocarbons produced in the same way.

It is also considered possible that sundry volcanic phenomena may be due to the same cause, and that the variety of carbon compounds, from asphalt down to carbon dioxide, produced in the final manifestations occurring in volcanic centres, probably result from the polymerisation of the gases liberated by the contact of water with subterranean stores of metallic carbides.—C. S.

PATENTS.

Gas [Wood], Impts. relating to the Manufacture of, and to Apparatus therefor. H. Riché, Lisors par Lyons-la-Forêt, France. Eng. Pat. 10,947, June 1, 1895.

The object of this invention is to convert the whole of the non-mineral constituents of wood into gas. The apparatus consists essentially in a vertical retort, which is charged from the top, and from which the gas-outlet pipe is situated near the bottom. After the first charging of the retort the wood is fed in at the top as required, the ashes being removed from the bottom from time to time. In this way the lower part of the retort is constantly filled with an incandescent mass of carbon or charcoal, and the patentee claims that by causing the gases first formed (containing large quantities of steam, &c.) to pass over this incandescent mass a "rich and perfectly pure gas is obtained, ready for immediate use as fuel, as illuminating gas for incandescent gas light, or as a source of motive power."

—L. T. T.

Gas, Heating and Illuminating [Acetylene], Impts. in Apparatus for the Production of. T. Thorp and T. G. Marsh, both of Manchester. Eng. Pat. 12,356, June 26, 1895.

Two forms of apparatus are described. In one the generating chamber is a fixed chamber in a tank, and containing a fixed tray to hold the carbide, and having communication at the bottom with the water in the surrounding tank. When acetylene is generated faster than it is used, the pressure of the gas forces the water down in the generator and so removes it from contact with the carbide.

In the second apparatus the generator forms a bell or holder, rendered buoyant by air-tight chambers or counterpoise weights, and surrounded by a tank of water. In this case when excess of acetylene is produced the generator is lifted, and the carbide thus removed from contact with the water.—L. T. T.

Gas, Illuminating [Poor-Gas with Acetylene], Impts. in the Manufacture of. T. L. Willson, New York, U.S.A. Eng. Pat. 13,750, July 18, 1895. (Date under Internat. Convention, Dec. 19, 1894.)

WHILE a non-illuminating gas, such as water-gas, cannot be economically rendered illuminating by the addition of

acetylene, the patentee claims that a gas of low illuminating power, but already containing hydrocarbons, can be efficiently and economically enriched by the addition of acetylene. He states that, for instance, a poor gas of nine candle-power can be raised to an illuminating power of 25 candles by the addition of 10 per cent. of acetylene.—L. T. T.

Gas, Illuminating [Acetylene modified], Impts. in the Production of. T. L. Willson, New York. Eng. Pat. 13,766, July 18, 1895. (Date under Internat. Convention, Dec. 19, 1894.)

If acetylene be added to a non-luminous combustible gas in its ordinary condition, the illuminating power of the acetylene is, after a short time, practically lost. The patentee claims, however, that by employing the gaseous products obtained from heating acetylene, the illuminating power remains. The acetylene is either passed through red-hot retorts, and the products then introduced into the non-illuminating gas, or the acetylene is first added to the latter gas, and the mixed gases are then passed through fixing retorts or tubes, raised to a bright red heat.—L. T. T.

Calcium Carbide, Impts. in the Production of. T. L. Willson, New York, U.S.A. Eng. Pat. 15,360, Aug. 15, 1895.

LIME and coke, which have been finely powdered and then thoroughly mingled in a grinder or mixer, in the proportion of 35 per cent. of coke and 65 per cent. of lime, are fed into a vertical furnace enclosed in brickwork, and preferably lined with carbon, and provided with a tap-hole at the bottom for the removal of the fused product. The lower electrode is formed of broken carbon, and the upper, which is removable, is of compacted carbon, and is connected with an adjusting mechanism by which it may be raised or lowered. The electrodes are connected to the poles of an alternating-current dynamo having a mean potential of 55 volts, and the reversals of the current may be satisfactorily run at about 50 a second. The amperage, which depends on the size of the furnace, may be 1,500 amperes for a pole of 8 ins. on the side. It is claimed that by this process the difficulty of feeding in between the poles is overcome, and that the output of calcium carbide per electric horse-power is nearly double that which is obtained with a direct current.—G. H. R.

Carbide of Calcium, Impts. in the Process and Apparatus for the Production of. R. P. Pictet, Geneva, Switzerland. Eng. Pat. 9358, May 2, 1896.

A CUPOLA is provided with a ring of tuyères at about two-thirds of its height from the bottom, and with a ring of blow-pipes at about one-third of its height; the electric arc is formed at the bottom of the furnace. Air is injected through the tuyères, and hydrogen and oxygen (water-gas and enriched air) respectively through the separate pipes which form each blow-pipe. The charge of lime and excess of coke is heated by the combustion of a part of the coke to 2,000° C. at the tuyères, to 2,400° C. at the blow-pipes, and to above 3,000° C. at the electric arc. Here the calcium carbide is formed, and flows from the bottom of the furnace in a fused condition, making room for a fresh charge at the top. To protect the furnace lining from the heat of the arc, the exit pipe is made to protrude into the furnace, so that a residuum of calcium carbide remains in the bottom of the cupola, where it partially solidifies on the lining.—A. G. B.

Carbonic Acid, Obtaining, from Gas Mixtures in the Dry Way, An Impd. Process for, and Apparatus therefor. P. W. Raydt, Stuttgart, Germany. Eng. Pat. 13,456, July 12, 1895.

See under VII., page 594.

Coking Processes, Impts. in. J. Bowing, Tilbury, Essex. Eng. Pat. 14,682, Aug. 2, 1895. Compare this Journal, 1891, 628.

STREAM coal may be coked by powdering it until it can pass through $\frac{1}{4}$ -in. mesh, thoroughly wetting it, mixing it with some $\frac{2}{3}$ per cent. of its weight of tar, and ramming it into a gas-tight vessel, so that it shall be as solid as possible

and the vessel shall be quite filled. The vessel is then raised to the coking temperature, and the products allowed to escape through a suitable orifice. In the case of coals which swell when heated, the tar and water may be dispensed with, provided the other conditions be fulfilled. The slack of coals which do not swell much may be merely weighted during the coking process. When dealing with coals which coke with difficulty, the volatile products from one coking chamber should be passed into the next chamber either just prior to or during the beginning of the coking operation; the particles of the newly coking mass become thus cemented together.—A. G. B.

Liquid Hydrocarbons for use as Fuel. An Impd. Process for Treating. P. Baumbert, Berlin, Germany. Eng. Pat. 21,709, Nov. 15, 1895.

THE admission of steam into the combustion chamber is but little aid to perfect combustion of liquid hydrocarbons, but if water be mixed with the hydrocarbon and the emulsion be injected, a better result is obtained. Such an emulsion may be prepared by adding to the hydrocarbon, up to 3 per cent. of its weight of the powdered stems and woody parts of such plants as *Salix viminalis*, *Spiraea filipendula*, *Prunus spinosa*, and the like; the resulting mixture can be emulsified with from 10 to 95 per cent. of water.—A. G. B.

Oil or other Liquid, Evaporating, and Mixing the Vapours Produced with Coal-Gas. Impts. in Apparatus for. F. S. Cripps, London. Eng. Pat. 6008, March 18, 1896.

THE apparatus consists of an iron or steel vessel divided into three chambers, the bottom one being termed the heating chamber, the middle one the mixing chamber, and the top one the oil-arresting chamber. The oil flows through a pipe in the form of an ascending volute contained in the heating chamber, and is delivered on to the floor of the mixing chamber, which serves as an evaporating disc; this disc and the volute are heated by low-pressure steam admitted into the heating chamber. The coal-gas main enters the mixing chamber at the centre of the evaporating disc. The gas thus becomes mixed with the oil vapour and then passes through the perforations in the floor of the arresting chamber, where any liquid oil particles are removed by a column of coke. By a suitable bye-pass arrangement either the whole or a portion of the gas to be enriched may be sent through the apparatus. An advantage claimed is the absence of injectors.—A. G. B.

Gas, Illuminating [Petroleum Spirit, &c.]. Impts. in Apparatus for Producing. C. Gautsch, Münster, Germany. Eng. Pat. 8239, April 18, 1896.

SPECIFICATION describing the production of an illuminating gas by carburetting air. Air is compressed into a chamber and then forced through numerous very fine openings in a tube arranged near the bottom of another chamber filled with a hydrocarbon, such as "ligroine" (petroleum spirit), naphtha, &c.—L. T. T.

III.—DESTRUCTIVE DISTILLATION. TAR PRODUCTS, Etc.

Petroleum in the Island of Tschelken. K. Charitschkoff. Chem. Rev. Fett u. Harz Ind. 1896, [39], 86—88.

ATTENTION has recently been directed to Tschelken as an oil-producing region, in consequence of the success attending the prospecting carried on by the Transcaucasian authorities in seeking new sources of liquid fuel, and the firm of Nobel has resumed boring operations.

Tschelken petroleum is very thick, being, at 9° C., of the consistence of ointment, and setting at a little below 0° C. Some difficulty is occasioned in distillation by the disinclination of the contained water to separate out. The specific gravity of the oil is 0.868, and the flashing point 51.5° C., Abel-Pensky. Fractional distillation yields the following results:—

Up to 200° C.	2.8 per cent. of sp. gr. 0.7712 at 16.5° C.
200°—250° C.	11.9 " " 0.795 "
250°—270° C.	7.6 " " 0.8005 "
270°—310° C.	6.6 " " 0.8128 "

The residuum has a specific gravity of 0.900 at 22.5° C., is salve-like at the ordinary temperature, and may be worked

up direct into vaselin. The percentage of paraffin in the oil is high (5.5, yielding about 3 per cent. of refined paraffin), so that a sediment forms at moderately low temperatures. Two kinds of burning oil can be obtained: the first of sp. gr. 0.7945 at 15° C., flashing point 20° Abel-Pensky, and greatly resembling American petroleum, burning very brightly at first, but falling off a good deal towards the end. The second oil is of sp. gr. 0.8216, flashing point 75°, and does not burn so well, but when the two are mixed together a very satisfactory burning oil of sp. gr. 0.800, and flashing point 35°, is obtained, indicating the possibility of preparing from Tschelken petroleum a very good safety oil for special purposes, as well as the establishment of the vaselin and paraffin industries, not hitherto developed to any extent in the Caucasus.—C. S.

Petroleum of Salt Creek, Wyoming. W. C. Knight and E. E. Slosson. School of Mines (University of Wyoming) Bulletins, Petroleum Series No. 1, June 1896.

THE Salt Creek oil-field lies around the river of that name, but its limits have not yet been ascertained, only a small area having hitherto been tested. Wells have been sunk by three companies about 50 miles north of Casper, and a small refinery has lately been erected, containing one 50-barrel cheese-box still.

The oil is believed to occur in two horizons of oil sands, one of which crops out at about two miles from the existing wells, and dips some 555 feet per mile, the other being indicated by oil springs about two miles further away. The existing wells vary in depth from 809 to 1,200 feet, and are lined by three strings of casing; the average daily production is 10 barrels. In 1895, 7,019 barrels were obtained, and the yield for the present year is estimated at 20,000. Only small quantities of gas are given off from the wells. The water associated with the oil contains a large percentage of sodium sulphate. Drilling is rather expensive, the cost of plant and labour for a first well amounting to 6,000 dol.; and both coal and wood are very dear, but it is expected that workable coal will be found within 8 or 10 miles. In geological age the oil-field is younger than those of the Eastern States, and more nearly approximates to the Hungarian, Galician, and Bukovina oil-fields.

The crude oil is bright red by transmitted, and dark green by reflected light. Its specific gravity at 15° C. is 0.9095; at 70° C., 0.8755; flashing point (open cup), 210° C.; burning point, 260° C.; viscosity (Engler) at 20° C. (water = 1), 15.74; at 100° C., 1.49. No paraffin is deposited on cooling, and the oil remains liquid at -17° C. The chemical composition has not yet been studied, but judging from the violent action of concentrated acids, a large proportion of unsaturated hydrocarbons seems probable. The heating power is 10,813 calories per gm.

Details are given of experimental distillations, with and without superheated steam, air condensers being used for fractionating; and the authors consider that the best results, seeing that the oil is naturally suited for the production of lubricating oil, will be obtained by a process of continuous distillation on the lines of the Russian method, "cracking" being prevented by the use of superheated steam, which has been found to increase the yield of distillate with a sp. gr. of 0.900—0.925 from 22.94 to 29.98 per cent., a gain of 7 per cent., and of that of higher specific gravity than 0.925 from 4.96 to 12.53 per cent., a gain of about 7½ per cent. At present two chief grades of lubricating oil are manufactured, viz.:—

	Specific Gravity.	Viscosity at 20° C.	Flashing Point.
Car oil	0.9065	15.05	Above 215° F.
Engine oil	0.9125	25.17	" 273° F.
	Burning Point.		Cold Test.
Car oil	Above 265° F.		Below -17° C.
Engine oil	" 325° F.		" -15° C.

—C. S.

Tar and Petroleum Oils, Action of Aluminium Chloride on; Theory of Formation of Petroleum. F. Reusler. *Zeits. f. angew. Chem.* 1896, **11**, 318—321.

It may be stated generally that the action of aluminium chloride upon a mixture of saturated, unsaturated and sulphur-containing hydrocarbons may be so directed that the removal of the last two classes may be achieved. Apart from the practical value of this observation, it is of interest to know of the existence of a reaction, which apparently is capable of affording means for determining the percentage of saturated hydrocarbons even in mixtures of very various composition. Armed with this knowledge, one may determine the proportion of unsaturated substances in crude petroleum distillates or in petroleum badly refined or adulterated with oils from brown coal and shale distillation.

With regard to the theory of the origin of petroleum, the author endeavours to elaborate Engler's hypothesis. On treating some of Engler's distillate, boiling from 100° to 120° C., with aluminium chloride, about 60 per cent. of saturated hydrocarbons were left unattacked, the remainder of the material being converted into a resinous mass. A highly viscous oil boiling at 190° to 280° C. under 15 mm. pressure and resembling an ordinary mineral lubricating oil, was also isolated. The following percentages of saturated hydrocarbons were found in various mixed raw materials:—Brown coal-tar, 61.5 per cent.; shale oil, 62 per cent.; fish-oil distillate (according to Engler), 61 per cent.; petroleum from Alsace, 95 per cent.; Ohio petroleum, 97 per cent. From these results the author deduces that the fish-oil distillate of Engler approaches a shale oil rather than a true petroleum, but that from it can be prepared oil precisely similar to that characteristic of true petroleum. Accepting Engler's main hypothesis, the natural formation of petroleum may be considered as taking place in two stages, viz., (1) the resolution of fats by distillation under pressure; (2) the removal of the unsaturated bodies by a process corresponding with that formulated by the author. Whether aluminium chloride or some other agent was concerned in this change cannot be definitely stated.

With regard to the presence of naphthenes in certain petroleum, it may be noted that these hydrocarbons have been found in the distillation products of brown coal and in those of Scotch shale. Bituminous substances therefore exist which are capable of yielding this particular class of petroleum hydrocarbons on being subjected to destructive distillation.—B. B.

Wood, Yield of Charcoal, Methyl Alcohol, and Acetic Acid from Different Kinds of. E. Barillot. *Rev. de Chim. Ind.* 1896, **7**, [76], 100—102.

Two series of experiments were carried out—one in the laboratory and the other on a manufacturing scale, as mentioned this Journal, 1896, 346 and 347.

For the laboratory experiments, retorts of a capacity of $\frac{1}{2}$ cb. m. were used, which were connected with a condenser, and the liquid portions, pyroligneous acid and tar, were collected in a tared receiver. The gaseous products, by means of an exhauster, were conducted through a scrubber charged with coke, where the ascending gases met a fine spray of descending cold water. The greater part of the acid, alcohol and acetone, which escaped condensation was here absorbed. The liquid from the scrubber was then collected for analysis, so as to determine the proportion of useful products lost in actual manufacture.

The method of analysis was as follows:—After saturating the acid with milk of lime, the alcohol was distilled off according to the directions of Gay-Lussac, that is, until 50 per cent. of the original volume had passed over. But, in order to recover all the alcohol present in the crude liquor, the residue, after having been slightly acidified with sulphuric acid, was submitted to a further distillation until another 50 per cent. passed over. The distillate was purified by fractional distillation over an excess of lime until a clear spirit of 96°—98° (alcoholometric degrees) was obtained. This crude alcohol still contained the ethers and acetones produced from the wood, but are included in and returned as methyl alcohol in the first table, page 347.

The acid was titrated with normal soda, using phenolphthalein; and though there are also other acids present in the crude liquor, they are here, for purposes of comparison, all included as acetic acid, and in the table following as calcium acetate. All the quantities given, represent the yield from 100 kilos. of wood, and must be regarded as maxima, as they were obtained by slow and very regular distillation. The results demonstrate that for the production of alcohol, mixtures of barked beech and elm are to be preferred to either round or split cord-wood, and the latter to split beech. For the production of charcoal, white woods should be rejected.

In the experiments on the large scale the same methods were employed as those used in the laboratory experiments. See second and third tables, page 347.—I. S.

IV.—COLOURING MATTERS AND DYES.

Solvents, Some New [for Induline Dyestuffs]. Ch. Gassmann. *Mém. Scient.* 1896, **10**, 348—350.

The author refers to the use of levulinic acid (Ger. Pat. 34,515) and of the acetyl derivatives of glycerin (Ger. Pat. 37,064) as solvents for the indulines. The high price of the former tells against its employment in practice. Whilst the acetyl derivatives of glycerin give excellent results, it is curious that the formic derivatives are not satisfactory. The latter are readily obtained by heating glycerin with either oxalic or formic acid, and the product readily dissolves the indulines; after some time, however, the solution becomes of a greenish colour. This change may be due either to a reduction of the induline at the expense of the COH group or to a condensation resulting in the formation of a di- or triphenylmethane derivative. Glyceryl-acetal, obtained on heating a mixture of glycerin and acetic aldehyde, is also a good solvent for the indulines, but this solution also becomes greenish, and the results obtained on printing are very unsatisfactory. On the other hand, good results are obtained with the glyceride of levulinic acid and its acetyl derivative. These compounds dissolve 25—30 per cent. of induline, and on printing with these solutions, good and regular shades are obtained. The glyceryl derivative of tartaric acid dissolves 40—45 per cent. of induline at 130°—140°. The pastes obtained, do not precipitate on dilution with water or acetic acid, and are satisfactory for printing. The product of its acetylation dissolves 25—30 per cent. of induline.

The above solvents are not satisfactory in the case of the rosindulines or of naphthaeridine.—A. K. M.

Thiorescinol. O. Hesse. *Ann.* 1895, **289**, 61—70.

Thiorescinol [$110.C_6H_4.O.C_6H_4.O.C_6H_4.OH$] is formed by heating (at 85° for 72 hours) resorcinol (4 grms.) with glacial acetic acid (4—6 c.c.) and fuming hydrochloric acid (4 c.c.). It is thus obtained (yield, about 60 per cent. of the theoretical) in combination with hydrochloric acid, from which it is freed by boiling with water.

It is also produced in small quantity, instead of the corresponding diamido compound, when resorcinol (one part) and *m*-amidophenol (two parts) are heated together under the above conditions.

It forms (+ $2\frac{1}{2}$ H₂O) small prisms, which appear yellow by transmitted, and dark purple by reflected light, with a metallic lustre. It is sparingly soluble in cold water, alcohol, &c., its solutions displaying an intense green fluorescence, and it dyes from an alkaline bath, cotton and silk, mordanted with tannic acid, and unmordanted wool, a fast yellow colour. It decomposes at above 130° without melting.—E. B.

Dimethyl-m-amidophenol, Reactions of. L. Lefèvre. *Bull. Soc. Chim.* 1896, **15**, 900—904.

The author does not confirm v. Rothenburg's conclusions (*J. prakt. Chem.* **51**, 578; this Journal, 1895, 992), and points out that resorcinol when heated on the water-bath does not give a fluorescent substance and that this is only formed in presence of a condensing agent and at temperatures above 100° C. Hence v. Rothenburg's test for the position of a carboxyl group requires further investiga-

tion. Several reactions of dimethyl-*m*-amidophenol are described, the substance itself being obtained by fusing dimethylaniline-*m*-sulphonic acid with an alkali. It melts at 83°–85° C. and boils at 265°–268° C. (Ger. Pat. 44,702). When heated for 3–4 hours at 145°–150° C. the residue dissolves easily in very dilute hydrochloric acid, and after filtering, a red fluorescent solution is obtained somewhat similar to that of rhodamine, but the shade on silk has neither the brilliancy nor the strength of that colouring matter. A somewhat stronger colouring matter can be obtained by employing zinc chloride. Neither pyrocatechol, hydroquinone, salicylic acid, nor β -resorcylic acid give colouring matters with dimethyl-*m*-amidophenol, and the two latter substances give off carbonic acid during condensation. The condensation product obtained with benzoic acid is not a phthalein but is similar in its tinctorial properties to the rosanilines which are obtained by the action of phenylchloroform on dimethyl-*m*-amidophenol. Certain fatty acids, such as citric or tartaric acid, give colouring matters on heating with dimethyl-*m*-amidophenol, but these will require further investigation to determine whether they can be classed as phthaleins.—T. A. L.

Quinazine and Oxazine Dyestuffs, Researches on. R. Möhlau and K. Uhlmann. Ann. 1895, 289, 90–130.

THE authors adopt the nomenclature for the indamine, indophenol, and allied compounds, proposed by Nietzki (Ber. 25, 2994; this Journal, 1893, 137), that is, the names azine and azone to designate colouring matters, the chromophors of which are nitrogen atoms in the *p*-positions to nitrogen and oxygen atoms respectively, their derivatives being termed oxazines, thiazines, oxazones, &c.

Basic Azones.—*Dimethylamidodibromodiphenazone*—

is obtained by the action of dibromoquinonechlorimide (m.pt. 78°) on dimethylaniline. It decomposes, when heated, without melting; is insoluble in water, with difficulty soluble in cold alcohol and ether, more readily in hot alcohol, acetic acid, &c.; it crystallises from pyridine in needles; dissolves in dilute acids (in alcohol, &c.) and in concentrated sulphuric acid with a blue colour, the solutions changing colour on the addition of water, owing to the azone decomposing: it is completely decomposed by prolonged boiling with dilute hydrochloric acid into ammonia, dimethylamine, dibromo-*p*-amidophenol, dibromoquinone and quinone.

Phenolic Azones.—The sole representative of this group hitherto known has been the *p*-hydroxydiphenazone prepared by Hirsch (Ber. 13, 1907). Its dibromo-derivative—

is produced by the interaction of dibromoquinonechlorimide and phenol, and resembles it closely. Both compounds are very sensitive to acids.

To ascertain whether the stability towards acids of the members of the group could be increased by introducing into the molecule acidic groups, such as COOH, or by increasing the molecular weight, compounds were prepared from dibromoquinonechlorimide and salicylic acid and α -naphthol respectively (β -naphthol was found not to react with the formation of a colouring matter).

The first of these—*o*-hydroxydibromodiphenazonecarboxylic acid—

—forms a brown-red powder, which dissolves with difficulty in water and chloroform, but easily in alcohol and ether. It is decomposed when heated with acids. Its sodium salt is insoluble in ether, but very soluble in water and alcohol, the colour of the solutions being bluer than those of hydroxydibromodiphenazone. Like the latter, it gives a pale brown-red solution when heated with dilute alkalis, which, on cooling and exposing to air, becomes blue.

The second compound—*hydroxy-naphthodibromodiphenazone*—

—crystallises in brown-red needles; decomposes, without melting, at about 201°, and is soluble in alcohol and ether with an orange colour, but insoluble in water; acids decompose it on heating. Its sodium compound is readily soluble in water and alcohol with a purple-blue colour (redder than that of the solutions of the sodium salt of the compound last described), and is insoluble in ether. The aqueous solution does not change colour on adding alkalis and heating.

Oxazines.—*Dimethylamidophenonaphthoxazine*—

is formed when nitroso-dimethyl-*m*-amidophenol hydrochloride and α -naphthol are boiled together in acetic acid solution. The base crystallises from pyridine in long prisms which display a beautiful green surface-lustre, and appear by transmitted light reddish-brown. It melts at 244°, is insoluble in water, soluble in hot alcohol, chloroform, &c., with a cherry-red colour and scarlet fluorescence. It forms two series of salts, both of which are dissociated by water; of these, the monacid salts may be isolated (from chloroform) and are stable in dry air.

The diethyl compound is very similar to the foregoing.

Oxazines.—*Tetramethylamidophenonaphthoxazine iodide*—

is of interest, on account of its relationship to Methylene blue. It is obtained (in very small quantity) by the interaction of dimethyl-*m*-amidophenol and nitroso-dimethyl-*m*-amidophenol hydrochloride in acetic acid solution, and conversion of the resulting easily soluble chloride into the less soluble iodide, by the addition to its solution of potassium iodide. It is soluble in water, acetone, and chloroform, with a blue colour and powerful brown-red fluorescence; it is not affected by dilute acids, ammonia or caustic soda in the cold; the latter on heating give a blue precipitate, doubtless of the free base. It is dissolved by concentrated sulphuric acid with a brown-red colour, which changes to blue on the addition of water.—E. B.

Violet and Blue [Triphenylmethane] Colouring Matters. A Method for Preparing. Weinmann (J. R. Geigy and Co.). Bull. Soc. Ind. Mulhouse, 1896, 201.

A SEALED note, deposited February 16, 1885.

It describes the production of colouring matters by the conjoint oxidation of tetramethyldiamidodiphenylmethane and certain aromatic amido bases, namely:—diphenylamine, from which a blue-violet dyestuff was obtained, which, it was found, could be readily sulphonated; dimethylaniline, the product from which was a crystallisable violet dyestuff; and phenyl- α -naphthylamine, which yielded a soluble blue dyestuff, from which a sulphonic acid derivative was prepared. Colouring matters were also prepared from primary aromatic amines, which were employed in the form of their acetyl derivatives.

The intermediate formation of tetramethyldiamidodiphenylcarbinol or of tetramethyldiamidobenzophenone was not observed.—E. B.

Hydrols [Diphenyl Carbinols] and Aromatic Amines, Condensation of, in presence of Concentrated Sulphuric Acid. M. Prud'homme. Bull. Soc. Chim. 1896, 717–720.

By condensing *p*-nitro-amido diphenyl carbinol (benzhydrol) with benzylaniline, dibenzylaniline, or ethyl-benzylaniline

in presence of concentrated sulphuric acid, violet-red colouring matters are obtained, very different from the more or less bluish fuchsines produced when the condensing agent is hydrochloric acid and alcohol. Nitrodiethylamidodiphenyl carbinol gives bluish-greens, whilst tetramethyldiamidodiphenyl carbinol, on condensation with the above bases, gives leuco compounds which on oxidation yield pure greens. These three series of colouring matters are derivatives of the following types:—

where R is an alcoholic radical $\text{CH}_2\text{C}_2\text{H}_5$, &c. A compound of the second type has been prepared by dissolving *p*-nitro-diethylamidodiphenylcarbinol in a mixture of equal weights of benzene and sulphuric acid, and allowing the whole to stand for 48 hours at the ordinary temperature. The triphenylmethane derivative, after separation from the benzene, is converted into a bluish-green colouring matter by the author's method for the synthesis of *p*-fuchsine. The influence of the condensing agent in determining the position at which condensation takes place was first pointed out by Noetting, who showed that with tetramethyldiamidodiphenyl carbinol and *p*-toluidine, the condensation occurs in the *meta* or *ortho* position relative to the amidogen, according as to whether hydrochloric or sulphuric acid is employed. In the latter case the colouring matter obtained is a bluish-green, which on benzylation gives a greenish-blue. The direct condensation of the carbinol with dibenzyl-*p*-toluidine in sulphuric acid gives a pure green. It is assumed that in this case the condensation takes place in the benzyl and not in the benzene nucleus; and as a matter of fact, on condensing benzylamine with the carbinol in presence of sulphuric acid, a base is obtained which gives a green on oxidation. Benzylamine can also be condensed with *p*-nitrodiethylamidodiphenyl carbinol by means of sulphuric acid, and subsequent reduction and oxidation gives a corresponding colouring matter, *viz.*, a bluish-green, but no condensation of benzylamine, and any of the three carbinols mentioned above could be effected by means of hydrochloric acid and alcohol. Hence benzylamine in its condensations behaves like an aromatic hydrocarbon, and is, in fact, a toluene substituted in the side chain. Benzylaniline, dibenzylaniline, and ethylbenzylaniline in presence of concentrated sulphuric acid act like dibenzyl-*p*-toluidine and benzylamine. The corresponding colouring matters may be considered as diamidotriphenylmethane derivatives, giving violet-red, bluish-green, or green shades, according as to whether the amidogens are unsubstituted or are partially or wholly so. With regard to the manner in which the condensation takes place, some light is thrown on this by a condensation, carried out by the author, of tetramethyldiamidodiphenyl carbinol and diethylaniline. Equal parts by weight of these two substances are heated with 15 parts of concentrated sulphuric acid for 24 hours to 95–100° C. The melt is then poured into water and steamed, to expel the excess of diethylaniline. The leuco base so obtained, after oxidation with acetic acid and peroxide of lead, gives a colouring matter which dyes wool and silk blue. It is, however, a mixture of a violet and a green, which can be separated by salt, the former being precipitated. The violet corresponds to a normal condensation para to the amido group, whilst the green corresponds most probably to a condensation in the ortho position. It would thus appear that condensations between a hydroxyl (carbinol) and an amine take place in presence of concentrated sulphuric acid, and preferably in the para position when this is unoccupied.—T. A. L.

Benzylated Parafuchsines. M. Prud'homme. Bull. Soc. Chim. 1896, 720–723.

By condensing *p*-nitro-amidodiphenylcarbinol, *p*-nitrodiethylamidodiphenylcarbinol, and *p*-nitrobenzaldehyde with mono-

and dibenzylaniline and with ethylbenzylaniline in alcoholic solution by means of hydrochloric acid, nine new fuchsines have been obtained. The colouring matters produced are either bluish fuchsines or reddish-violets, but the effect of the benzylation as regards blueness, although analogous, is inferior to that of a methylation. The increase in molecular weight does not appear to have a preponderating effect; thus dibenzylaniline has less effect than ethylbenzylaniline. With a view of testing the applicability of this rule to parafuchsines benzylation in three nuclei, the author has condensed ethylbenzylaniline with *o*-formic ether in presence of zinc chloride. The leuco base is oxidised with chloranil and the colouring matter obtained is a violet intermediate between hexamethyl and hexa-ethyl violet. Hence benzylation is equivalent to methylation, that is to say, the C_6H_5 group in $\text{C}_6\text{H}_5\text{CH}_2$ is without action on the colour, and it would appear that this difference between the phenyl and benzyl derivatives is due to the fact that, in the former case, C_6H_5 is directly united to nitrogen, whilst, in the latter, CH_2 is interposed.—T. A. L.

PATENTS.

Phthaleins, Manufacture of, by the Action of Mixed Anhydrides [Rhodamines]. A. Fischesser and Co., Lutterbach, Germany. Eng. Pat. 13,949, July 22, 1895.

THE manufacture of phthalein colouring matters by the action of mixed acid anhydrides on resorcinol, *m*-amidophenol, cresol, and their alkyl and phenyl derivatives is claimed, also the colouring matters so produced.

The mixed anhydrides are obtained by the action of the chloride of one acid on a salt of the other in molecular proportions; thus, phthalyl succinyl anhydride by the following reaction:—

The anhydride condenses with the phenol on heating the two together without dehydrating agents. The new rhodamines obtained by this process produce on wool and silk fine bluish-red shades, extremely fast to acids, soda, soap, air, and light. They are well suited for cotton dyeing.

—A. C. W.

Dyestuffs [Basic] and Chemical Compounds derived from Phenolic Bodies, The Manufacture or Production of. H. E. Newton, London. From "The Farbenfabriken vormals F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 14,488, July 30, 1895.

ACCORDING to Eng. Pat. 8988 of 1895 (this Journal, 1896, 349), new products were obtained by the action of phenols or naphthols on primary or secondary fatty amines in presence of formaldehyde. These products had the general formula $\text{O.C}_6\text{H}_5:\text{N.R}:\text{C}_2\text{H}_5$, R being an alkyl group. Thus, for instance, the action of dimethylamine on phenol in presence of formaldehyde yields dimethyl-*exo*-amidomethylphenol ether, $\text{C}_6\text{H}_5\text{O.CH}_2\text{N}(\text{CH}_3)_2$. It has now been found that such products can be converted into isomeric compounds, that last mentioned yielding hydroxybenzyl-dimethylamine, $\text{HO.C}_6\text{H}_4\text{CH}_2\text{N}(\text{CH}_3)_2$. In order to carry out this reaction, the products are heated either alone or in presence of a solvent or diluent together with the addition of a small quantity of an alkali, or an acid, or of certain salts. The following is a typical example:—An alcoholic solution of 2.1 kilos. of *p*-acetamidodimethyl-*exo*-amidomethylphenol ether, $\text{CH}_3\text{CONH.C}_6\text{H}_4\text{OCH}_2\text{N}(\text{CH}_3)_2$ (obtained from 1.5 kilos. of *p*-acetamidophenol, 0.8 kilo. of a 40 per cent. formaldehyde solution, and 0.9 kilo. of a 50 per cent. dimethylamine solution), is heated on the water-bath until a sample dissolves in caustic soda-lye. The resulting product has the formula—

and melts at 110° C. This process can also be applied for the production of colouring matters, and several new basic dyestuffs have thus been obtained. For instance, 1.35 kilos. of a 33 per cent. dimethylamine solution and 0.75 kilo. of a 40 per cent. formaldehyde solution, are run into 20 litres of alcohol containing 1.98 kilos. of benzene-azo-phenol. The mixture is cohobated on a water-bath for

several hours until the action is complete. After distilling off the alcohol, the residue is dissolved in hydrochloric acid, and the hydrochloride of the colouring matter is salted out and filtered off. It has the formula—

and dyes cotton mordanted with tannin, yellow shades fast to alkalis. In a similar manner, muscarine (obtained from nitrosodimethylaniline and 2,2'-dihydroxynaphthalene) can be converted into a new colouring matter. For this purpose, 3.26 kilos. of it mixed with 30 litres of alcohol are cohabited as above with the same quantity of dimethylamine and formaldehyde. The new dyestuff is separated in the same manner. It is more soluble than muscarine, and tanned cotton dyed with it gives blue shades fast to alkalis. The new product has the formula—

—T. A. L.

Azo Colouring Matters [Yellow to Brown], and of New Bases for Use therein, Manufacture of. O. Imray, London. From "The Farbwerke vormals Meister, Lucius, and Bräuning," Höchst a/M., Germany. Eng. Pat. 11,494, July 30, 1895.

THE new bases referred to are amido-ammonium bases of the general formula $\text{H}_2\text{N}\cdot\text{A}\cdot\text{N}(\text{X})_2$, where A is an aromatic radicle, R is an alkyl group, and X is a halogen. These products are obtained by reducing the corresponding nitro-ammonium bases or the azo-ammonium bases, or even by alkylating diamines in which one amido group is protected by an acetyl group, which is subsequently split off. The nitro-ammonium bases are obtained by alkylating the nitro bases, or nitrating the corresponding ammonium bases. About 2 kilos. of *m*-nitrophenyltrimethyl ammonium chloride are mixed with 5 litres of water and 5 kilos. of hydrochloric acid and reduced with 2 kilos. of zinc turnings. On concentrating, the zinc chloride double salt of *m*-amido-phenyltrimethylammonium chloride separates out. It may be freed from zinc by adding the calculated amount of sodium carbonate, filtering, evaporating, and extracting with alcohol, when the product forms colourless tablets readily soluble in hot alcohol and water. The following is an example of another method employed:—*p*-Acetyl-amido-dimethylaniline, melting at 130°C ., is heated on the water-bath with one molecular proportion of methyl iodide. The resulting *p*-acetamidophenyltrimethylammonium iodide is tolerably soluble in water and melts at 325°C . The corresponding chloride melts at 215°C ., and crystallises in small scales from alcohol. On boiling with 6–10 per cent. hydrochloric acid it yields *p*-amidophenyltrimethylammonium, and the double zinc salt may be precipitated from the solution by means of zinc chloride, or the solution may be employed directly for the production of azo colouring matters. By nitrating β -naphthyltrimethylammonium in concentrated sulphuric acid, the resulting nitro- β -naphthyltrimethylammonium sulphate yields, when reduced with zinc and hydrochloric acid, amido- β -naphthyltrimethylammonium chloride, which gives a sparingly soluble zinc chloride double salt. All these amido-ammonium bases can be diazotised and combined with phenols and amines in the usual manner; for instance: 1 kilo. of the zinc chloride double salt of *m*-amidophenyltrimethylammonium dissolved in 10 litres of water is diazotised with 0.7 kilo. of concentrated hydrochloric acid and 0.195 kilo. of nitrite. When combined with β -naphthol in presence of acetic acid, a yellowish-red powder is produced. By substituting resorcinol for the β -naphthol either a mono- or disazo colouring matter can be obtained. The process can be further modified by forming first of all amido-azo colouring matters, which subsequently are converted into ammonium azo colouring matters. For instance: diazotised dimethyl-*p*-phenylenediamine is combined with β -naphthol, and the resulting *p*-dimethylamidobenzene-azo- β -naphthol is heated with methyl iodide at 90° – 100°C . The original dark blue mass is converted into an orange-yellow product soluble in water. All the colouring matters produced according to the

preceding methods dye tanned cotton yellow and reddish-yellow to brown shades. The specification contains a table showing various dyestuffs obtained and some of their reactions.—T. A. L.

Anthraquinone Derivatives, The Manufacture or Production of. H. E. Newton, London. From "The Farbenfabriken vormals F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 14,686, Aug. 2, 1895.

THE introduction of hydroxyl groups into anthraquinone is covered by the following patents:—Eng. Pats. 8725, 12,715, 17,712, and 18,729 of 1890 (this Journal, 1891, 567, 759, and 917); 4871, 13,677, and 21,717 of 1891 (this Journal, 1892, 513, 749, and 1000); 1657, 12,579, and 12,580 of 1892 (this Journal, 1893, 142 and 596); 14,345 of 1893 (this Journal, 1894, 723); and 973, 974, 975, 2325, and 3113 of 1894 (this Journal, 1895, 30,144, and 146). According to the present specification the process can also be carried out by the use of perchloric acid or its salts, the following being typical examples:—10 kilos. of potassium perchlorate are carefully stirred into a hot solution of 10 kilos. of anthraquinone in 200 kilos. of fuming sulphuric acid containing 20 per cent. of SO_3 , the temperature being kept below 150°C . The first products are quinizarin and the like, but these are further oxidised, yielding hexahydroxyanthraquinone sulphonic acid, and the product can be separated from the melt in a suitable manner. 6 kilos. of potassium perchlorate are stirred into a solution of 10 kilos. of alizarin in 200 kilos. of the above fuming acid, the temperature being kept below 30°C . After stirring for some hours, the melt is poured into 2,000 litres of ice-water containing 10 kilos. of sodium bisulphite. The whole is then boiled and filtered, the residue consisting of hexahydroxyanthraquinone, which may be purified in a suitable manner.—T. A. L.

Black Colouring Matters of the Anthraquinone Series suitable for Directly Dyeing Cotton in the Cold Bath, The Manufacture and Production of. J. Y. Johnson, London. From the "Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 15,242, Aug. 13, 1895.

IN Eng. Pat. 10,996 of 1893 (this Journal, 1894, 630), the action of alkaline reducing agents on the dinitronaphthalenes is described, giving rise to black cotton dyestuffs. By applying this process to the dinitro-anthraquinones, diamido-anthraquinones, or to the intermediate products obtained by the action of alkaline sulphides on nitro derivatives of anthraquinone, black colouring matters are produced, which dye cotton directly from a cold alkaline bath in shades fast to light, acids, soap, or chlorine. The products are soluble in water, giving bluish-green or violet-blue solutions which are precipitated by acids. About 250 kilos. of crystallised sodium sulphide are heated with 75 kilos. of sulphur until saturated, when about 50 kilos. of 1,4-di-*o*-nitro-anthraquinone are added, and the whole is heated until a sample is completely soluble in water. The resulting solid mass may be used directly for dyeing, or suitably purified. It dissolves in water with a blue colour, in concentrated sulphuric acid with a greyish-black, and in alcohol with a green colour, but it is insoluble in acetone. Mineral acids or acetic acid precipitate the aqueous solutions, and the precipitate is readily soluble in alkalis and alkaline sulphides, the solutions dyeing cotton black.

—T. A. L.

Colouring Matters of the Rosinduline Series, Manufacture of. C. D. Abel, London. From "The Aetien-Gesellschaft für Anilin Fabrikation," Berlin, Germany. Eng. Pat. 16,217, Aug. 29, 1895.

THESE colouring matters can be obtained by the oxidation of equimolecular proportions of α -naphthylamine and *o*-amidodiphenylamine sulphonic acid or derivatives of these substances. Corresponding rosinduline derivatives may also be obtained by heating together α -naphthylamine and *o*-nitrodiphenylamine sulphonic acid. The two following examples illustrate these methods:—A mixture of 17.1 kilos. of ethyl- α -naphthylamine and 26.5 kilos. of *o*-amidodiphenylamine sulphonic acid dissolved in dilute hydro-

chloric or acetic acid is treated with ferric chloride solution or with a solution of 20 kilos. of sodium bichromate. The ethylsulphadine sulphonic acid, which is sparingly soluble in water, separates out. 25 kilos. of α -naphthylamine, 10 kilos. of α -naphthylamine hydrochloride, 16 kilos. of nitrodiphenylamine sulphonic acid, and 5 kilos. of zinc chloride are well stirred together and heated for 4–5 hours at 140°–150° C. After cooling, the melt is powdered and extracted with dilute hydrochloric acid, when the rosinduline sulphonic acid remains undissolved as a greenish powder. It is sparingly soluble in soda-lye and dilute acids. The rosinduline derivatives thus obtained may be converted into readily soluble sulphonic acids by subsequent sulphonation.—T. A. L.

Dis- and Polyazo Dyes [Cotton Dyes] by Oxidation, Impts. in the Manufacture of. B. Willeox, London. From the "Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 17,260, Sept. 16, 1895.

This is an improved method of obtaining the colouring matters produced according to Eng. Pat. 12,303 of 1895 (this Journal, 1896, 351). For instance, in the manufacture of Congo red, benzene azo-naphthionic acid was oxidised in sulphuric acid solution by manganese peroxide. The patentees, according to the present specification, carry out the oxidation by means of an electric current, the following details being given:—A solution of about 50 kilos. of α -toluidine-azo-naphthionic acid (sodium salt) in 750 kilos. of 91 per cent. sulphuric acid is placed in a porous cell containing the positive electrode of platinum or other suitable material. The porous cell stands in another vessel containing concentrated sulphuric acid and the negative electrode. A current of about 4 amperes per sq. dec. at 5–6 volts is then passed through the cell until no further change of mono- to disazo-dyestuff takes place. The solution is then poured on to ice, filtered, washed, and converted into the sodium salt.—T. A. L.

Mangrove Bark, Impts. relating to the Treatment of, for the Obtainment therefrom of Pure Solid Tannin, Dye, and Cutch. W. Clarke, Singapore. Eng. Pat. 17,402, Sept. 18, 1895.

MANGROVE bark, either dry or fresh, and in small pieces, or pulverised, is boiled in water for 12 hours, more or less. The strained-off liquor is evaporated to half its bulk, and to it is added a suitable quantity of "either ammonia, potash, soda, or any other alkali or alkaline carbonate, mercurial chloride, gum ammoniacum, alum, or borax." The boiling is now continued until a semi-solid mass is obtained, which is then cut into suitable pieces and dried by sun heat, or otherwise.

To obtain 1 picul = 133½ lb. of "solid tannin, dye, or cutch," 533½ lb. of bark are treated with 150 gallons of water, and 30 oz. of alum, or 20 oz. of borax or fixed alkali, or 5 oz. of "mercurial chloride," gum ammoniacum, or ammonia, are added.—E. R. B.

Pyrocatechin-anhydro-monoacetic Acid, Processes for the Manufacture of. Chemische Fabrik von Heyden, Radebeul, Germany. Eng. Pat. 8154, April 17, 1896.

THE above substance is claimed as a new product, with the following processes for its manufacture. Pyrocatechin is heated with monochloroacetylchloride and precipitated chalk:—

Also pyrocatechinmonoacetic acid, its esters, or amide, on heating, yield the anhydro acid.—A. C. W.

Black Azo Dyestuffs on the Fibre, Process for Producing. E. Ritter von Portheim, Prague, Bohemia. Eng. Pat. 9912, May 9, 1896.

THE process consists in impregnating the cotton fibre with sodium- β -naphtholate and applying the diazo compound of an amidochrysoidine. The proportions employed for producing the diazo compound are given in the following

example:—A mixture of 5.3 kilos. of amidochrysoidine (triamido-azobenzene), 7 kilos. of hydrochloric acid (sp. gr. 1.2), 75 litres of water, and 45 kilos. of ice, is diazotised by adding a concentrated solution of 1.78 kilos. of sodium nitrite. The diazo solution is mixed with 110 kilos. of acetic starch paste, 5.3 kilos. of oxalic acid, and 2.4 kilos. of sodium acetate. It is claimed that deep shades can be obtained which are fast to light.—T. A. L.

V.—TEXTILES: COTTON, WOOL, SILK, Etc.

Vegetable Textile Fibres, Lignification of. A. Herzog. Chem. Zeit. 1896, 20, 461.

THE amount of lignin in the various fibres named below was determined by Zeisel's method, as amended by Benedikt, Hamberger, and Grüssner, the methyl number of pure lignin being taken as 52.9:—

Nature of Fibre.	Water.	Lignin in Fibre Dried at 100°
SEED-HAIRS:—		
Cotton, <i>Gossypium barbadense</i> (Sea Island).....	Per Cent. 7.40	Per Cent. ..
Cotton-silk, <i>Bombax speciosa</i>	6.77	12.90
" <i>Calotropis gigantea</i>	6.68	15.46
Typia angustifolia.....	7.07	18.08
(MONOCOTYLEDONOUS.) FIBRE BUNDLES:—		
Manilla hemp, <i>Musa textilis</i> (hackled).....	7.81	30.11
Agave americana (hackled).....	7.10	16.02
Aloe, <i>Aloe perfoliata</i> (hackled).....	7.90	17.22
Cocoa-nut, <i>Cocos nucifera</i>	7.36	41.59
Tillandsia, <i>Tillandsia usneoides</i>	8.19	21.13
(DICOTYLEDONOUS.) BAST FIBRES:—		
Common nettle, <i>Urtica dioica</i> (bleached).....	8.15	..
China grass, <i>Boehmeria nivea</i>	7.84	1.46
Jute, <i>Corchorus capsularis</i>	8.06	40.26
Paper mulberry, <i>Morus papyrifera</i>	6.03	4.74
Linen, <i>Linum usitatissimum</i> (Russian) (imperfectly retted) (broken).....	8.40	0.92
Linen (Belgian; Courtrai) (hackled).....	8.71	..
Hemp, <i>Cannabis sativa</i> (Italian) (hackled).....	7.93	5.33
Hemp, <i>Cannabis sativa</i> (Polish) (hackled).....	8.20	5.41

The fibres examined, with the exception of those of the common nettle, were in the unbleached state. As is well known, a portion of the lignin is removed in the process of bleaching.

The lignin imparts harshness to the fibres, and unfavourably affects their elasticity and suppleness.

It is pointed out that, as unbleached hemp and linen are widely differentiated by their methyl values, the determination of the latter will afford a sure means of distinguishing these fibres from each other.—E. B.

Carbon Tetrachloride [Solvent] as a Substitute for Petroleum Spirit. Neueste Erfind. u. Erfahrungen, 1896, 3.

CARBON tetrachloride, by reason of its solvent action on tar, grease, paraffin, stearin, &c., and the unflammable nature of its vapour, is well calculated to replace petroleum spirit for cleansing purposes. It may also be used in conjunction with the latter substance, since the inflammability of the petroleum spirit is considerably reduced, combustion being gradual and the flame greenish, with copious evolution of smoke. The tetrachloride also combines with absolute alcohol, ether, oils, and soaps, and is useful in the caoutchouc industry, for brocade printing, and bronzing. It combines with benzine soaps, and may, by suitable treatment, be invested with considerable washing power; this effect may be increased by the addition of ammonium chloride, and acetic acid may be added for preserving certain colours, both these ingredients being first mixed with alcohol.

Being heavier than water the latter may be used as a seal to prevent the evaporation of the tetrachloride.

In removing grease spots, carbon tetrachloride is preferable to petroleum spirit, since it does not leave marks round the edges of the greasy places.

Experiments on the behaviour of the tetrachloride towards woollen and silk stuffs dyed with aniline colours failed to reveal any action on the latter, and it is therefore assumed there would be no influence exerted on colour-shades. Satisfactory results were also obtained in testing the resistance of the various "finishing" materials for textiles.—C. S.

Cotton Warps. Sizing and Dressing, Alsation Methods of.
E. Ackermann and V. Ackermann. Rev. d. Chim. Ind. 1896, 7, [76], 102—104.

THERE are two methods of preparing cotton warps for weaving, technically known as "dressing" and "sizing." The former is used for the finer and the latter for coarser yarns. For "dressing," the composition is used tepid, and is applied by brushes moving in the same direction as the yarn, to give smoothness to the latter without the sizing completely effecting penetration. For "sizing," on the contrary, the yarn is passed through the composition, which is hot and less concentrated than in the former case, so that the yarn is saturated and retains a more or less woolly surface. The chief ingredient used for sizing in Alsace is farina, starch being seldom used on account of its high price. To this are added fatty or other substances, such as oil, tallow, soap, glycerin, &c., to give the cloth a soft handle, and glutinous substances (gum, dextrin, size) to give adhesiveness, but which must not be used in large quantities or the yarn becomes stiff and brittle. To prevent mildew, sulphate of copper or zinc is added to the size, and often also pipe-clay, kaolin, &c. In the following table are given some of the compositions used for dressing:—

No.	Water.	Farina.	British Gum.	Sulphate of Copper or Zinc.	Yellow Wax.	Glycerin.	Fermented Farina.
	Litres.	Kilos.	Kilos.	Kilos.	Kilos.	Litres.	Kilos.
1	100	8.30	0.250	0.084
2	"	20.00	1.900	0.250	0.530	0.250	..
3	"	16.00	0.600	0.250	0.500	0.250	..
4	"	10.00	0.150	0.150
5	"	12.00	0.100	0.200	1.200
6	"	7.00	..	0.200	0.200

No. 2 is used for yarns of Nos. 12—18, intended for cretonnes; No. 3 for those of 24—30 for twills; and 28—40 for figured cloth and crêpes. In general, larger quantities of farina are used for coarser threads. By experience it has been found that in "sizing," the yarn absorbs 15—30 per cent. of its weight of size and 6—12 per cent. in "dressing," or about 10—15 grms. per skein of 100 m. in the former and one-third of this quantity in the latter.

The following table gives a few formulæ of compositions used for sizing:—

Litres.	Kilos.	Kilos.			
700	100	Tallow.....	4.50	Soft soap	3 kilos.
"	"	".....	5.00	"	4 "
"	"	Gommeline ..	5.00	Glycerin	7 litres.
"	"	Glyxiogomme	2.00	"	8 "
"	"	Soda crystals	1.35	Tallow...	8 kilos.
"	"	Cornflower...	1.00	" ...	8 "

—L. S.

Tussah Silk, The Examination of, in Textile Fabrics.

F. Filsinger. Chem. Zeit. 20, 324.

See under XXIII., page 619.

PATENTS.

Peat Fibre, to be used for making Sheets or Laps of Fibre, Threads, or Surgical Dressings, An Impd. Process and Apparatus for the Preparation of. G. A. Cannot, London. Eng. Pat. 12,331, June 25, 1895.

THE peat fibres are washed in running water, in which they are agitated; then they are dried more or less completely, and, finally, are worked in carding engines.

The apparatus claimed for the first of these operations consists of a movable frame carrying rods or bars, arranged in a vessel provided with pipes for the supply and discharge of water, the bars on the movable frame passing, as the frame is raised and lowered, between similar bars on a frame affixed to the vessel.—E. B.

Flax and Hemp, Impts. in and connected with Retting.
G. Loppens and H. Deswarte, Nieuport, Belgium. Eng. Pat. 14,781, Aug. 3, 1895.

THE retting is performed in a tank with vertical sides and a perforated false bottom. Inlet and outlet water-pipes are placed between the bottom and false bottom, the first at a higher level than the second, their size being sufficient to allow the water to pass in and out without producing eddies or whirls.

The flax or hemp is made up into bundles, which are arranged vertically on the false bottom of the tank, and are prevented by suitable means from rising in the water.

In virtue of "the superior density of the juice given out by the stems," this sinks to the bottom of the tanks and is replaced by fresh water, uniform action being thus secured with the use of "a minimum supply of water."—E. B.

Wool, Cotton-Waste, and like Materials, Impts. in Degreasing and Cleansing, and in Apparatus therefor. F. N. Turney, Nottingham. Eng. Pat. 14,978, Aug. 8, 1895.

THE materials (loose wool, &c.) to be operated upon are laid upon a canvas band and wound with it upon a roller. The roll thus formed is placed inside an "air-lock," A, at the entrance end of a system of vapour tight tanks, a, in which the operations of cleansing or "degreasing" are performed, the object being to keep the apparatus, when closed, supplied for a considerable length of time with the materials to be treated.

(See next page for illustration.)

The materials, which, as the roll is unwound, fall away from the supporting band, are carried along progressively by endless travelling bands through the tanks, and are subjected to heating and squeezing while immersed in or saturated with the volatile solvent (carbon disulphide, "petroleum spirit," &c.) employed. They pass next into a drying chamber, B, being again deposited upon a series of endless travelling bands, and are dried in a current of hot air, the vapours escaping from the chamber passing through a condenser, for the recovery of the solvent. The dried materials are received in an "air-lock" at the exit end of the apparatus, whence they are removed after a sufficient quantity has accumulated therein.—E. B.

VI.—DYEING, CALICO PRINTING, PAPER-STAINING, AND BLEACHING.

Textiles, Chemical Technology of; Report on the Progress made during 1895 in the. O. N. Witt and A. Buntrock. Dingl. Polyt. J. 300, 185—191.

Bleaching.—A continuation of report of 1895 (Dingler's Polyt. J. 295, 233). The reference there made to the combined ozone-hypochlorite process of bleaching (this Journal, 1895, 33) is now supplemented, the process having since been successfully tried in a Silesian linen bleach works (Oesterreichs. Wollen u. Leinen Ind. 1895, 746). Seven hours' ozonising is said to be equal to four days' "grassing" for a $\frac{1}{2}$ -bleach; for a full bleach the process is repeated three or four times. The tints obtained by the two processes vary slightly, the former giving a yellowish, and the latter a bluish-grey white.

To bleach satins composed of raw silk and unbleached cotton, L. Tabourin (Bull. Soc. Ind. Mulhouse, 1895, 351) recommends 10 per cent. barium peroxide suspended in water at 40°—60°. Hydrogen peroxide in alkaline solution is also said to give good results.

"Scrooping" Woollen Yarn.—A silky lustre and "handle" may be conferred on wool (Oest. Wollen u. Leinen Ind. 1895, 634) by the following process:—The cleansed and still wet material is treated for 10—30 minutes in a cold bath (for heavier yarns warm up to 70° C.)

[See page 589.] APPARATUS FOR DEGREASING AND CLEANSING WOOL, COTTON-WASTE, &c.

containing 5–10 grms. of sulphuric acid per litre. Hydro-extract, work 20–30 minutes in a cold solution of bleaching powder (5–15 grms. per litre), rinse well, soap 20–30 minutes at 30°–70°, with 5–10 grms. of soap to the litre, pass again through acid bath, rinse, and dye with acid colours to required shade. This process is said to intensify considerably the affinity of the wool fibre for colouring matters. Its felting properties, however, are diminished, whereby the use of the process is limited to knitting and hosiery yarns. It is stated that hard, lustrous mohair fibre is the most suitable for this treatment.

Silk.—E. Herzog (Färber Zeit. 6, 201) gives the following characteristics whereby to distinguish artificial (*Chardonnet's*) from natural silk. Artificial silk does not possess the crisp feel and crunching sound ("seroop") peculiar to boiled-off natural silk. In potassium hydrate solution artificial silk dissolves with a yellow colour, while the solution of natural silk is colourless. The behaviour of most other solvents is the same towards both fibres, with the exception of the alkaline copper glyceride solution (10 grms. of copper sulphate dissolved in 100 grms. of water and 5 grms. of glycerin, and just sufficient potassium hydrate to re-dissolve the precipitate formed), in which Chardonnet's silk is insoluble, whereas natural silk is completely dissolved by this reagent. (See also J. Soc. Dyers and Col. 1896, 115.)

Dyeing of Unions.—To dye mixed goods of wool and cotton with substantive colours exactly to shade, G. Mecklenburg (Färber Zeit. 6, 197) concludes that the safest method is to use mixtures of such colouring matters as will dye in a neutral boiling bath one or other of the two fibres only.

Mixed Colours on Piece-Goods.—The process for dyeing silk, woollen, or cotton cloths in different colours by mordanting one part only of the threads of silk, wool, or cotton, patented by Zillesen (Eng. Pat. 4984, 1892; this Journal, 1893, 261), is stated on the authority of L. Schreiner (Färber Zeit. 6, 229) to be specially adapted for the production of two-coloured cotton goods. The dyeing to shade in a single bath is alleged to be very easy, and calculations as to cost are given in the original paper.

Removing Stains.—The stains on the white parts of cloth, caused by the bleeding of the dyed portions during the process of milling, may be completely removed in the case of certain alizarins and many of the azo colouring matters, according to F. Geissler (Färber Zeit. 6, 145), by passing the cloth through a solution of sodium thiosulphate.

Artificial Dyes for Army Cloth.—As a result of careful investigation and comparative trials, the Prussian War

Office has sanctioned the use of certain artificial colouring matters for the dyeing of army cloth, and instructions have been given that in future cloths thus dyed shall be accepted, provided they answer to the following tests.

p-Nitraniline Red on the Fibre.—V. Werner, who made investigations as to the best method of preparing the diazo solution of *p*-nitraniline, arrived at the following results (Färber Zeit. 6, 294):—The nitraniline should be dissolved in boiling water before the requisite quantity of hydrochloric acid is added, and then cooled quickly so as to ensure a fine division of the nitraniline hydrochloride. The solution should be complete, as any undissolved portions are not acted on by the nitrite. If too little of the acid be taken, the diazo solution soon decomposes, and too large an excess of acid produces yellowish shades, and requires larger quantities of sodium acetate. With less than the theoretical quantity of nitrite, the diazotising will be incomplete, causing the formation of an insoluble, brownish-yellow, flocculent precipitate, while an excess favours decomposition; but in practice it has, nevertheless, been found best to use a small excess of nitrite. A properly prepared diazo-hydrochloride solution does not commence to decompose, even at 23°, until after 1½ hours' standing; and at lower temperatures will keep, it is alleged, for months. The addition of sodium acetate greatly favours the decomposition, and in proportion as the acetate solution is more concentrated. On these observations Werner bases the following method for the diazotising of *p*-nitraniline as the most suitable:—5 kilos. 520 grms. of *p*-nitraniline are dissolved in 16 litres of boiling hot water, and 11 litres of pure hydrochloric acid of 22° B., to which are then added 40 litres of cold water and 40 kilos. of ice. When cooled down to 0°, 2 kilos. 888 grms. of sodium nitrite dissolved in 20 litres of cold water are quickly added, and the whole is stirred. After 15 minutes' standing, the clear solution is made up to 160 litres. For use, 20 litres of this stock solution are diluted with 60 litres of cold water, and then 2 kilos. 500 grms. of sodium acetate dissolved in 20 litres of water added thereto. Soda may be substituted for part of the acetate, taking care, however, that the solution remains distinctly acid after such addition; the remaining free hydrochloric acid being then neutralised with sodium acetate.

A bluish shade of Nitraniline red may be obtained, according to a patent specification of the *Farbwerke Hoechst* (German application refused), by adding to the sodium naphtholate solution small quantities of the sodium salt of $\beta_1\beta_2$ -naphthol-sulphonic acid (F acid of Cassella). An addition of 5 per cent. is said to be sufficient to produce a

TABLE FOR TESTING ARMY CLOTH (GERMAN ARMY) DYED WITH FAST ARTIFICIAL COLOURING MATTERS.

Kind of Cloth.	(a.) Immerse for two minutes in cold dilute HCl (1 part strong acid to 3 of water) and rinse at once in cold water.	(b.) Boil for one minute in dilute HCl as under (a).	(c.) Put a drop of strong HCl on cloth, and after five minutes press between filter paper.	(d.) Boil for two minutes in 15 per cent. acetic acid, let solution cool, shake up with ether, and add 2-3 drops of a solution of equal parts stannous chloride, strong HCl, and water.
Dark blue cloth for coats, I. and II. Russian blue cloth. Dark blue molton. Grey cloak cloth.	The colour to turn only slightly redder. Solution should not turn a distinct red. (Absence of log-wood.)	The solutions should be according to the different colouring matters used, reddish to bluish-violet, giving with soda-lye of 20° B. after a short time, a reddish-blue to bluish-green precipitate. The colour of the fibre with this test is immaterial.
Black cloth.....	The colour of the fibre should not alter much, and the solution should be nearly colourless. (Logwood turns the acid red.)	Solution should be only slightly reddish, and should turn to greenish-blue or become decolorised with soda-lye of 20° B. The boiled and well-rinsed cloth, on being heated with soda-lye, to yield a blue to greenish-blue solution.	Colour may change, but not to red; filter paper must not show a red stain. (Logwood.)
Dark blue cloth (black mixed with white).	As above.....	Solution red to violet, turning, when supersaturated with soda-lye, blue to greenish-blue, and, after some time, a reddish-blue to bluish-green precipitate. The fibre, washed free from acid and heated with soda-lye, should yield a blue or greenish-blue solution.	As above.....
Green cloth.....	Colour of cloth must not change materially. (Logwood would give a red solution.)	Solution brown-red to bluish-red, turning green with excess of soda-lye, and, after standing, green to blue precipitate. (Fustic with indigo does not give this precipitate.)	The upper layer of ether is coloured yellowish-red to bluish-red, but must not show a yellow fluorescence (fustic). Lower layer of water nearly colourless.
Brown cloth.....	Colour lighter.....	Yellowish-brown solution, giving, with sodium hydrate of 20° B., a greenish-black precipitate. Acidifying this with acetic acid and filtering, a brown residue is left, which turns yellowish-brown with HCl, and dark violet with NaHO.	As above.

distinct bluish shade equal, in fastness to soaping, to ordinary red.

To prevent the cotton cloth impregnated with naphthol solution from turning brown, Lauber and Caberti have patented the use of the addition to the alkaline naphthol solution of an alkaline solution of antimony oxide in glycerin. (See also this Journal, 1896, 111 and 112.)—I.S.

Indigo, Loss of, through Chroming. K. Ernst. *Färber Zeit.* 7, [18], 282-283, and [19], 298-300.

In chroming indigo-dyed wool, more or less of the indigo on the fibre is destroyed. To determine how far this destruc-

tion is favoured by the different auxiliaries in common use for chroming wool, the author has made a series of experiments, the results of which are given in the following table.

The horizontal columns give the percentage quantities used of the substances specified for each column, and the vertical lines represent the comparative degrees to which the indigo on the fibre has suffered destruction. No. 1 of the scale has been scarcely affected; in No. 20 the indigo has been completely destroyed, whilst the other numbers represent intermediate results:—

PATENTS.

Textile and other Materials, An Impd. Process for the Treatment of [Bleaching, &c.], and Apparatus therefor. G. C. Dymond, London. From La Société Lebleis Piceni and Co., Elbeuf St. Aubin, France. Eng. Pat. 11,453, July 30, 1895.

PERFORATED BOXES, K, containing the materials to be treated, are affixed to a shaft L inside a vessel which, when closed, will withstand considerable external pressure. The air is exhausted from the vessel, and the bleaching, &c.

liquors drawn in, their action being assisted by revolving the shaft and by drawing the liquors from the lower part of the apparatus and discharging them at its centre. Steam is supplied, and the bleaching, &c. liquors and air are introduced and withdrawn, as required, by the pipe H.—E. B.

Cotton, Wool, Silk, Jute, Rhea, China Grass, and other Fibrous Materials in a Raw, Manufactured, or Partly Manufactured State: Impd. Apparatus and Plant for Scouring, Bleaching, Dyeing, Impregnating, Digesting, Drying, Carbonising, and otherwise Treating. W. Hepworth-Collins, Bolton. Eng. Pat. 21,032, Nov. 7, 1895.

THE apparatus is a movable, cylindrical cage with a perforated bottom, serving as receptacle for the fibrous material to be operated upon, which is placed inside a chamber.

The lower portion of this chamber is formed into a cylinder, from, and to which, the treating liquors or gases are alternately forced and drawn through the mass of the materials lying above, by the motion of a piston in the cylinder.

The liquors, &c., may be heated by a steam-coil. Various combinations and modifications of the apparatus are described.—E. B.

Fabrics, Impts. in the Art of Fixing Dyes in [by Electricity]. C. M. White, London. From The Electro-Waterproofing and Dye-fixing Co., New York, U.S.A. Eng. Pat. 8318, April 21, 1896.

A process for "fixing natural dyes" on fabrics, accomplished by applying them in suitable solvents to the fabrics, either entirely over their surface or in parts (patterns) only, placing the impregnated fabrics in contact with an anode of an oxidisable metal, the oxide of which is

capable of acting as a mordant, and a suitable (carbon) cathode, and passing a current of electricity through to oxidise the surface of the anode and so produce a mordant which, as it is formed, shall combine with the colouring matter upon the fabrics and produce a colour-lake. The fabrics are next dried, and, if necessary, washed, to remove any colouring matter from the untreated portions.

It is stated that with plates of tin, lead, and aluminium 2—3 ins. in diameter, and a current of 20—30 volts, a treatment of the fabrics 10 seconds in duration is required.

—E. B.

VII.—ACIDS, ALKALIS, AND SALTS.

Sulphuric Acid, Arrangement of Plant in Manufacture of. R. H. Niedenführ. Chem. Zeit. 1896, 20, 583—584.

NEW principles for the arrangement of a sulphuric acid plant have been brought to light by work done during the past decade.

On the one hand, Lunge and Sorel have shown that the conversion of sulphurous to sulphuric acid going on in the chambers is due to the continuous formation and decomposition of nitrosylsulphuric acid, and that this reaction is improved with lesser concentration and higher temperature. On the other hand, the researches of Schertel and Retter have demonstrated that, working with a single chamber, the entering concentrated gases become, at the beginning of the system, excessively dilute, their power of reaction being thereby weakened and the duration of the process lengthened. All these investigators come to the conclusion that the acid formation is assisted by mixing the gases and by the impact of these on solid surfaces.

The value of a one-chamber system was thus decided; no results have, however, been given to show the value of single small chambers, nor the variation of this value according to the relative position of these in the system. The tendency of the inactive constituents of the gaseous mixture to lag in the passage through the system, prevents the answer to this question being arrived at by an estimation of the sulphurous acid at different points.

The only method is by direct measurement of the acid formed in each chamber, and the author gives some figures so obtained. The plant, worked without Glover or Gay-Lussac towers, was specially arranged for this investigation; the results show that too much must not be expected from making the chambers smaller.

The system consisted of five chambers and two after-towers of the following dimensions:—Chambers 1 and 2 had a ground area 4.25 × 4.25 m. and a height 6.55 m.; chamber 3 was 8.5 m. broad, 32 m. long, and 7.1 m. high; chambers 4 and 5 were each 4.3 × 8.3 m. in area and 6.75 m. in height. The two towers (6 and 7) were respectively 1.95 × 1.95 m. and 1.95 × 1 m. in ground area, and each was 6.35 m. high.

Sicilian sulphur (97—98 per cent.) was the raw material employed.

The table on next page shows the relation of the production in the single chambers.

On calculating the chamber space used for 1 kilo. of sulphur (from the acid produced), the following values are obtained:—

For Chamber 1:			
For 1,800 kilos. daily consumption,	1.068 cb. m.	per 1 kilo. sulphur.	
" 1,895 " " "	0.948 " 1 "		
For Chamber 2:			
For 1,800 kilos. daily consumption,	1.068 cb. m.	per 1 kilo. sulphur.	
" 1,895 " " "	0.948 " 1 "		
For Chamber 3:			
For 1,800 kilos. daily consumption,	1.567 cb. m.	per 1 kilo. sulphur.	
" 1,895 " " "	1.531 " 1 "		
For Chamber 4:			
For 1,800 kilos. daily consumption,	2.028 cb. m.	per 1 kilo. sulphur.	
" 1,895 " " "	2.128 " 1 "		
For Chamber 5:			
For 1,800 kilos. daily consumption,	2.375 cb. m.	per 1 kilo. sulphur.	
" 1,895 " " "	2.235 " 1 "		
For Chambers 6 and 7:			
For 1,800 kilos. daily consumption,	3.984 cb. m.	per 1 kilo. sulphur.	
" 1,895 " " "	3.731 " 1 "		

Number of Chamber.	Chamber Space in Cu. m.	Kilos. H ₂ SO ₄ produced from		Kilos. H ₂ SO ₄ produced per 1 Cu. m. Chamber Space from		Percentage of Total Production from

Totals and Averages.	2686'1	5,971	5,336	2'24	2'42	100'00	100'0

These results show that Schertel's proposal to estimate the acid formed from the percentage of sulphurous acid in the ingoing and exit gases would lead to error. Thus, while chambers 1 and 2 produce the same quantity of acid per cu. m., the working capacity of the large middle chamber is lessened only to the extent of 50 per cent., and chambers 4 and 5, which are fed with very dilute gases, show a result only slightly less than half that of the first and second. Schertel's figures may be explained by the fact that the active gases travel more quickly through the system, leaving the inactive gas in the so-called dead space of the chambers; this phenomenon goes on until a definite limit has been attained. This tendency to lag is less with smaller chambers, but the above figures show that the division of the chamber space into a large number of smaller chambers leads to a constantly decreasing advantage. The author concludes that the best way to obtain the necessary surface for good working in a small compass is by using the Lunge-Rohrman plate-towers. (See this Journal, 1896, 541—543.)

—J. T. C.

Sulphuric Acid, Concentration of. E. Loew. Zeits. f. angew. Chem. 1896, [9], 259—262.

THE methods at present in use for concentrating sulphuric acid may be grouped as follows:—

- (1.) Concentration by means of distillation.
- (2.) Concentration by means of air at a temperature when the acid possesses considerable vapour tension.
- (3.) Concentration by crySTALLISING the monohydrate from high-strength acids.

For the concentration of sulphuric acid by distillation, a great variety of apparatus has been tried, constructed of different materials, such as platinum, gilded platinum, glass, porcelain, or iron, but at the present time those made of platinum find most favour.

It is well known that sulphuric acid may be concentrated by means of hot air, the chief aim being to saturate the air with aqueous vapour and allow the concentrated acid to flow off.

It is by no means essential that the sulphuric acid should be maintained at its boiling point, as concentration will take place at lower temperatures with absolutely dry air; nevertheless, the higher the temperature the better, as the vapour tension increases, the nearer the boiling point is approached. The intensity of the work of concentration is determined by the difference between the absolute and maximum vapour tension of air and the vapour tension of the acid. The work of concentration is determined by—

- (1.) The heating surface.
- (2.) The volume, temperature, and dryness of the air.
- (3.) Loss by radiation and conductivity.

To make a calculation of the work of concentration, the following conditions are presupposed:—

- (1.) The acid to be concentrated has a temperature of 20° C., and contains 64·5 per cent. of monohydrate.
- (2.) The air leaves the apparatus saturated with aqueous vapour at 80° and 760 mm. tension; the acid formed is at its boiling point, and contains 95·6 per cent. of monohydrate.
- (3.) The air has a temperature of 20° at 760 mm. tension. From these figures the amount of heat required to produce 95·6 per cent. acid from 64·5 per cent. may be calculated,

and it will thus be found that 100 kilos. of acid require 49,500 cal. If, under the same conditions, the air should leave the apparatus saturated at 50·6°, 51,800 cal. would be required; on the other hand, saturated at 90° C., only 48,900 cal. are necessary.

The presence of carbonic acid in the gases, when obtained from a direct fire, has scarcely any influence on the figures quoted, whereas the presence of water, formed by the combustion of any material used for firing, would naturally be disadvantageous.

Theoretically, it is immaterial whether the heat be supplied by means of air or sulphuric acid. When concentrating in lead vessels, the acid is heated to 139°—150° C., and the air is allowed to heat itself and absorb aqueous vapour. By this means, however, it is impossible to saturate the air with aqueous vapour; even under the most favourable conditions the air will only be so far saturated that its tension for steam is equal to the vapour tension of the hot dilute sulphuric acid. The temperature of 140° C. is rarely exceeded in lead vessels, at which temperature the tension of an acid of 60 B. is inconsiderable, wherefore it is advantageous to cover such vessels in, thus making it possible to allow the air to escape at a temperature of 80°—90° C. In Kessler's apparatus the escaping air is caused to meet the acid to be concentrated, when it is possible for the air to have a higher tension than that of the acid to be concentrated, with which the air was last in touch. However, practically, it is impossible to utilise the air in such a manner that it shall escape, saturated with moisture, and it is therefore always necessary to employ an excess over the theoretical amount. This, however, still permits of a good utilisation of the heat supplied, and a production of an acid of any strength up to 98 per cent.—J. R.

PATENTS.

Sodium Cyanide, Manufacture of. W. McD. Mackey, Leeds, and J. F. Hutcheson, Glasgow. Eng. Pat. 6009, March 22, 1895.

IN Eng. Pat. 6925, 1894 (this Journal, 1895, 482), the inventors describe a process for obtaining potassium cyanide, consisting in heating together carbonaceous matter and some potassium compound, such as the carbonate, in a cupola subjected to blasts from specially arranged tuyères. To obtain sodium cyanide, the same process is now to be used, substituting a sodium compound for one of potassium.

—E. S.

Hydrocyanic Acid, Manufacture of. A. K. Huntington, London. Eng. Pat. 14,855, Aug. 6, 1895.

ACETYLENE and nitric oxide are drawn in about equal volumes into a cylinder provided with a piston as in a gas engine: the mixture is fired, preferably by an electric spark, and the products of the ignition, consisting mainly of carbonic oxide, hydrogen, and hydrocyanic acid, are expelled by the in-stroke of the piston, into, for instance, solution of soda or potash, to form a cyanide. The unabsorbed gases may be used for combustion.—E. S.

Cyanides. A Process for the Manufacture of. J. Pflieger, Kaiserslautern, Germany. Eng. Pat. 15,116, Aug. 10, 1895.

A MIXTURE of five parts of potash (carbonate of potash) and one of charcoal is placed in a crucible having a cap and escape tube. The crucible is heated to 900° C., and ammonia gas, at a certain pressure above that of the atmosphere, is forced in through a tube reaching to the bottom. More charcoal is then added. The operation is complete in about two hours, when the fixed product consists of pure cyanide. The reaction takes place according to the equation $K_2CO_3 + 4C + 2NH_3 = 2KCN + 3CO + 6H$. If an excess of carbon be added, it remains with the product, and may be separated by solution and filtration. Instead of ammonia, nitrogen or air may be used in the process; but if air be used, the proportion of charcoal must be increased. When nitrogen is used, a considerably higher temperature must be attained, but with air this increase of heat is given by combustion of the charcoal. The inventor points out the distinctions between his process and those of Siepermann and Beilby, which are stated to involve the preliminary production of cyanate.—E. S.

Chlorine, Impts. in the Manufacture of, from Hydrochloric Acid Gas. T. T. Best, A. Kay, and J. Brock, Liverpool. Eng. Pat. 13,451, July 12, 1895.

WHEN a mixture of dry hydrochloric acid gas and air is passed through a "Deacon's decomposer" or equivalent apparatus, part of the acid gas is decomposed into chlorine and aqueous vapour, and part remains unacted upon. According to the present invention, the residual gases are withdrawn, cooled, and freed from moisture by sulphuric acid or other hygroscopic substance, when the dried gases are passed through a second decomposer, and the process may be repeated until practically all the hydrochloric acid has been converted.—E. S.

Carbonic Acid, obtaining from Gas Mixtures in the Dry Way. An Impt. Process for, and Apparatus therefor. P. W. Raydt, Stuttgart, Germany. Eng. Pat. 13,456, July 12, 1895.

SODIUM or potassium carbonate is moistened, and exposed to the action of cooled gases of combustion, or of other carbonic acid gas mixture, when it becomes bicarbonated, according to the equation $Na_2CO_3 + CO_2 + H_2O = 2NaHCO_3$. The bicarbonate is then heated to obtain pure carbonic acid gas, which is collected and may be liquefied, and the recovered carbonate is again moistened for renewal of the process.

The carbonate is spread out on horizontal trays or wicker-work within a closed vessel, having an aperture at the bottom for admission of dilute carbonic acid gas, and an exit opening at the top. Perforated tubes, connected to small cisterns filled with the necessary quantity of water, and simultaneously discharged by gas-pressure, are suitably placed for moistening each layer of carbonate, several such layers being arranged, one above the other, within the apparatus. A pipe also circulates under and over each carbonate layer, carrying heating or cooling gases or water. For continuous working, several such apparatus are connected in series, so that in some vessels carbonic acid gas is being absorbed, and in others expelled by heat from the already formed bicarbonate. Gases of combustion, after passage through a lime-stone purifier, are led through the heating tubes of two apparatus in which the carbonate has already been bicarbonated, when pure carbonic acid is thus expelled; the fire gases are then taken through a cooler

and a washing vessel successively, and then pass through two apparatus containing moistened carbonate, to which they give up their carbonic acid, and the residual gases are allowed to escape. Provision is made for collecting and storing the carbonic acid gas evolved on heating the bicarbonate. The process is thus alternated in the different vessels of the series.—E. S.

Nitric Acid, Impts. in the Manufacture or Production of, and Apparatus therefor. C. Dreyfus, Manchester. Eng. Pat. 13,826, July 19, 1895.

SODIUM or potassium nitrate is heated with sulphuric acid in a still in which a vacuum is maintained to a regulated temperature, reaching from 170° to 190° C. The vapours pass into a receiver, then through a cooling coil, thence through a set of receivers and another cooling coil, and are then taken through a series of small receivers, alternately empty and partly charged with a liquid, which in the second vessel is sulphuric acid (to absorb nitrous fumes), in the fourth vessel, water, and in the sixth vessel, an alkaline solution. The vapours then pass up and through a tower containing coke, down which an alkaline solution trickles, an outlet pipe to the tower being connected to the air-pump or exhauster, which, by the described means, is preserved from injury by corrosive gases.—E. S.

Hydrochloric Acid, Impts. in and Apparatus for the Manufacture or Production of. C. Dreyfus, Manchester. Eng. Pat. 13,827, July 19, 1895.

THE distillation of sodium chloride with sulphuric acid to obtain hydrochloric acid, is conducted as is described in the preceding abstract in reference to sodium nitrate, except that the most suitable temperature is found in the present case to be about 260° C.; that the small receivers are all charged with water; and that two washing towers are used, the first for water and the second for an alkaline solution, the air-pump being connected to this tower as in the before-described process.—E. S.

Carbon Bisulphide, Impts. in Manufacture of, and Apparatus therefor. A. J. Holt, Manchester, and G. Millard, Droylsden. Eng. Pat. 14,912, Aug. 7, 1895.

THE improvement claimed in the process consists in passing sulphur vapour up through the carbon in the retort, and then returning the gases through the carbon to the bottom of the retort. The improved apparatus claimed, suitable for this process, has, in addition to the lid and exhaust-pipe at the top of the retort, an additional exhaust-pipe and a feed-pipe by which melted sulphur may be added, both at the bottom of the retort. The improvement may be applied to existing retorts.—A. C. W.

Certain Waste Materials, Impts. in Treating, to Produce Valuable Products, such as Plaster or Stiffening, Weighting, and Whitening Materials therefrom. J. H. Lester, Manchester, and T. E. Thomlinson, Bury, Lancaster. Eng. Pat. 15,283, Aug. 14, 1895.

THE residues of the process of treating ammonium sulphate with slaked lime, and other like residues, were directed, in Eng. Pat. 13,198, 1894 (this Journal, 1895, 483), to be treated with sulphuric acid; but the inventors have found it preferable to use hydrochloric acid, and, after separation of the solution from undissolved calcium sulphate, to precipitate the liquor with sulphuric acid. The calcium sulphate obtained is prepared for the applications named in the title by processes described in the cited patent, *loc. cit.* The dilute and impure hydrochloric acid remaining after the precipitation by sulphuric acid, is utilised in treating other portions of the calcareous residues.—E. S.

Galvanisers' Flux Skimmings, Impts. in the Treatment of. A. Wolf and W. S. Blythe, Church, near Accrington. Eng. Pat. 15,326, Aug. 15, 1895.

THE portion of the flux skimmings soluble in hot water is treated in solution with an alkaline carbonate in excess, and the precipitated zinc oxy-carbonate is separated. Lime is added to the residual solution to obtain ammonia. The zinc oxy-carbonate, or normal carbonate, is agitated with a hot solution of potassium chloride or sodium chloride, and

chlorine is passed in until the precipitate is dissolved; the solution is then filtered and concentrated, to obtain a chlorate of the alkali metal, which is crystallised out, zinc chloride remaining in solution.—E. S.

Kelp Liquor, Impts. in or relating to the Treatment or Utilisation of. J. W. Stevens, Horley, Surrey. Eng. Pat. 15,807, Aug. 22, 1895.

The first liquor obtained on lixiviating kelp is concentrated, and the alkali chlorides and sulphates are separated by crystallisation, the process being repeated until a mother-liquor is obtained rich in iodides. Sulphuric acid is then added, and, after addition of manganic oxide, the iodine and bromine are distilled off. The second and subsequent liquors are neutralised by hydrochloric acid, and after filtering off any separated sulphur, and concentrating to obtain a crop of potassium sulphate, "the liquor is electrolysed to convert chlorides, iodides, and bromides respectively into chlorates, iodates, and bromates." The chlorates are in part crystallised out, and the liquor again concentrated, or it is saturated with the alkali chlorides previously obtained and is "again electrolysed," the process being repeated until, it is stated, the liquor is sufficiently charged with iodates and bromates, which are then reconverted into iodides and bromides by sulphurous acid, from which the iodine and bromine may be obtained in the usual manner.—E. S.

Chlorine and Zinc, Impts. in and connected with the Production of. F. M. Lyte, London. Eng. Pat. 15,813, Aug. 22, 1895.

BLEND, or mixed ores of blende and galena, may be roasted, and the product lixiviated with dilute sulphuric acid, and the solution of zinc sulphate, after purification, treated with calcium or sodium chloride. After separation of the calcium or sodium sulphate formed, the solution of zinc chloride is evaporated to dryness, and may then be subjected to distillation to separate from non-volatile impurities. The zinc chloride is now heated to a temperature slightly above the melting point of zinc, and is then electrolysed, an anode of carbon and a cathode of fused zinc being used. As the zinc accumulates in the cell, it may be automatically siphoned off. The chlorine set free may be liquefied and stored. Residual galena from the treated ore may be worked by known processes to obtain lead and any precious metals that it may contain.—E. S.

Chlorine Gas, Process for Purifying. P. Jensen, London. From D. Cappelen and H. Cappelen, Gjemso Kloster, Norway. Eng. Pat. 9544, May 5, 1896.

THE chlorine gas produced in the electrolysis of alkaline chlorides is apt to contain impurities, and especially carbonic acid, which is objectionable in the use of the chlorine for making bleaching powder. It is found that when such impure chlorine is passed through milk of lime, that most of the carbon dioxide and but little of the chlorine is absorbed. The absorption vessels have pipe devices and are worked under pressure, the purified chlorine being led away through pipes provided with regulating valves. The chlorine water obtained as a by-product may be utilised in paper factories.—E. S.

VIII.—GLASS, POTTERY, ENAMELS.

PATENT.

Glass, Impts. in the Manufacture of Articles of. F. Kopp, Janstein, Moravia. Eng. Pat. 46, Jan. 1, 1896.

ARTICLES, such as bottle stoppers, which are commonly moulded by pressing a divided mould on a mass of plastic glass, are made, according to the present process, by the patented apparatus consisting of two half-moulds, initially closed, and arranged radially round a central reservoir provided with a piston serving to force plastic glass through radial channels into the moulds. By providing these moulds with cores, hollow goods may be produced. The depression of the piston and the insertion of the cores may be performed at one operation by connecting the piston with the cores by suitable links and levers.—B. B.

Glass Industry of Germany. U.S. Consular Reps., June 1896, 222.

See under Trade Rep., page 626.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Cement, Action of Water on. A. Stutzer. Zeits. f. angew. Chem. 1896, 11, 317—318.

THE author has had the opportunity of observing the action of water on the cement mortar used to line a reservoir for the supply of a small town on the Rhine. The reservoir had been built for nine years, and at the end of that time it was noticed that the cement mortar forming its lining had been converted into a brownish mud, which became softer in consistency as the bottom of the reservoir was approached. The bottom of the reservoir was partly stripped of its cement rendering. An examination of the water showed that it contained only 0.205 grm. per litre of total solids, largely consisting of calcium carbonate. Analysis of the unaltered mortar above the water line, and of the sludge below the water line, went to show that the greater part of the lime of the cement had been abstracted from the mortar below the water level. A similar result was observed in the case of another reservoir. In this case the water, regarded from a dietetic point of view, was of good quality, and the bulk of the mineral matter contained therein consisted of calcium carbonate. The author attributes the failure of the mortar of these two reservoirs to the solvent action of the carbon dioxide contained in the waters, and explains the greater effect observed at the bottom of the reservoir by the increased solubility of carbon dioxide at increased pressures. He further cites Michaelis concerning the behaviour of Portland cement towards solvents, in particular towards sea-water. That chemist, starting with the fact that during the setting of Portland cement a good deal of calcium hydroxide is set free, argues that the lime thus liberated is a source of weakness in that it is acted on by many substances with which the cement may be brought in contact, e.g., sea-water with its sulphates, magnesium salts and so forth. Further, loose compounds, such as calcium ferrite, may be attacked if the solvent be sufficiently active; the calcium aluminates are the next to go, the cementitious calcium silicate resisting longest. It is on account of these considerations that Michaelis recommends the addition to Portland cement of some active form of silica, such as trass, capable of combining with the lime, which would otherwise be set free as calcium hydroxide ready for attack by many solvents to the injury of the cement. The proportion of 125 parts of trass to 100 parts of Portland cement is stated to be suitable for this purpose. The author correlates these views (based chiefly on the observation of the action of sea-water on cement) with his own experience of the influence of fresh water containing carbon dioxide, the latter serving as a solvent for a portion of the lime essential for the strength and permanency of mortar made with Portland cement.—B. B.

PATENTS.

Peat, Impts. in the Process of and Apparatus for the Manufacture of different Articles from, and the Residue resulting from the Manufacture of Fibrous Peat, or from Peat Litter or its Residues. G. A. Cannot, London. Eng. Pat. 12,332, June 25, 1895.

PEAT, or peat litter or waste, is broken up, mixed with water, and incorporated with 20 per cent. of slaked lime or cement. The product, of clay-like consistency, may be incorporated with a variety of materials and moulded into bricks, or otherwise brought into a merchantable form. The articles that it is proposed to manufacture from material thus prepared are of a most varied kind, such as chimney pieces, paving tiles, roofing slates, waterproof cardboard, stocks for guns, &c., resembling carved ebony, artificial stone, &c.—B. B.

Composition, Impd. Plastic [for Sewer Pipes, Ducts, &c.], and Process of Combining the same. W. L. Woods, Washington, U.S.A. Eng. Pat. 25,013, Dec. 31, 1895.

A MIXTURE of 30 parts of magnesia, 60 of silica, 60 of sulphur, and 3—10 of "mineral wax" (e.g. ozokerite), is prepared by grinding and drying the silica and magnesia, melting the sulphur and wax, and pouring them into water repeatedly, following this by incorporating the whole of the materials at 300—500° F.

The product is used as a cement for any suitable aggregate, the resulting concrete mass serving for the manufacture of water ducts, sinks, battery jars, burial caskets, &c. In all underground work the material is said to be "imperishable."—B. B.

Wood, Method and Apparatus for Treating, for Fire-proofing or Preserving the same. A. M. Clark, London. Eng. Pat. 7032, March 31, 1896.

THE apparatus consists of a horizontal cylinder into which the wood to be treated can be run on cars, the wheels of which are supported by rails, while their axles project so as to pass beneath supplementary rails designed to prevent the rising of the car with its load from the main rails. The method of preservation consists in exhausting the cylindrical vessel, heating its contents, ejecting the gases and vapours arising from the wood, and treating the wood with a saturating liquid.—B. B.

Hot-Blast Blocks and Bricks, and Similar Apparatus. C. A. Brackelsberg, Steele, Germany. Eng. Pat. 8106, April 17, 1896.

THE bricks commonly used in hot-blast stoves are hexagonal in section, whereas in the present patented pattern they are triangular, the corners of the triangle being, however, hollowed out, so that where six such corners meet, a hole similar to that existing in the centre of the triangular brick is formed. In the next course the continuity is broken by placing a single block with its central hole over that formed in the way described. It is claimed that by this means a better bond is secured than by the usual practice.—B. B.

Fresco Painting, Impts. in or connected with. O. Matthiesen, Charlottenlund, Denmark. Eng. Pat. 10,000, May 11, 1896.

IN order to harden the surface of fresco and to neutralise the free lime which it contains, the patentee prescribes the distribution of pure carbonic acid under pressure over the plastic surface, while the latter is still wet and after the paints have been applied thereto.—B. B.

Firebricks, Impts. relating to the Manufacture of. J. G. Henry, T. E. W. Henry, and R. O. Henry, Jarrow. Eng. Pat. 10,293, May 14, 1896.

A MIXTURE of about equal volumes of lime water and "red liquor" (from the manufacture of soda-ash) is mixed with one of equal parts of sawdust and coke-dust in the proportion of about 3½ galls. of the liquid mixture to 1 cwt. of the coke- and sawdust mixture. Finely ground fireclay and ganister in the proportion of about 2 : 1, are mixed with the product described above, in the proportion of 4 cwt. of the former to 1 cwt. of the latter. Water is added until a consistency suitable for brick-making is reached, when the mass may be used for the production of firebricks, said "to be light and refractory."—B. B.

X.—METALLURGY.

Lead and Zinc Deposits of Iowa. A. G. Leonard. Eng. and Mining J. 1896, 61, 614.

THE lead and zinc ores are found in crevices, which widen out into several openings, in beds of galena limestone. The lead occurs as galena and the zinc as zinc carbonate. The zinc ore generally occurs a short distance beyond the lead, and if the ores are mixed, the amount is small.

The mine of the Dubuque Lead Mining Company has three shafts, 210 ft. deep, with a steam hoist on one, and "gins" (large wooden drums revolving in a horizontal

plane) on the other two. The ore-bearing dolomite forms a zone from 2 to 4 ft. wide, and contains an abundance of iron pyrites and galena. Up to the present, 100,000 lb. of lead ore have been raised.

The mine of the Lansing Mining and Smelting Company, in Allamakee County, extends 1,000 ft. horizontally; the vein is 3 to 4 ins. wide and 25 to 30 ft. deep in the main body of the mine. Since 1891, over 500,000 lb. of lead, and in the last two years over 250,000 lb., have been raised from the mine, although the output during the past year was small on account of the low price of lead.

The mine of the Dubuque Zinc and Lead Mining Company is worked by an open cut. The larger masses of the deposits are blasted, and the smaller ones loosened with the pick; the ore, when broken from the rock, is mixed with sand and small fragments of rock, and, after washing to free it from sand and dirt, is hand-picked. The output for the past few years averages about 2,500 tons per six months.

Several mines have been closed for nearly two years on account of the low price of zinc carbonate—5 to 6 dols. per ton, as against the former price of 12 to 18 dols. per ton. The price of lead is also low at present—17 dols. per 1,000 lb., as against 20 to 22 dols. formerly.

The output of the Iowa mines for the year 1895 was about 700,000 lb. of lead ore and 3,000 to 3,500 tons of zinc ore; but the zinc mines, which are capable of turning out 8,000 to 10,000 tons of ore per year, were closed during the greater part of the year.—A. S.

Diffusion of Metals. W. C. Roberts-Austen. Proc. Roy. Soc. 59, 281—285.

THE author states that owing to the want of sufficiently accurate methods, very little attention has been devoted to the measurement, or even to the consideration, of the molecular movements which enable two or more metals to form a truly homogeneous fluid mass. His own recording pyrometer for high temperatures used in conjunction with thermo-junctions renders it possible to measure and record the temperatures of diffusion of metals. Values have been thereby obtained for the diffusibility in square centimetres per day of various metals as follows:—

Gold in lead.....	3.19 at 500°
" bismuth.....	4.52 "
" tin.....	4.65 "
Silver in tin.....	4.74 "
Lead ".....	3.18 "
Rhodium in lead.....	3.04 "
Platinum ".....	1.69 at 190°
Gold in lead.....	3.03 "
Gold in mercury.....	0.72 at 11°

The diffusibility of sodium chloride in water at 18° is 1.04. No conclusions are at present drawn from these figures, but it is observed that the relatively slow rate of diffusion of platinum as compared with gold, points to its having the more complex molecule.

The diffusion of solid metals is then dealt with, first of all historically and then in consideration of the author's experiments. Cylinders of lead, with either gold or a rich alloy of gold and lead at their base, were maintained at temperatures below the melting point of lead for 31 days. After cutting the cylinders into sections and assaying, the following results were obtained:—

Diffusibility of gold in fluid lead at 550°	Per Sq. Cm. per Day.
" " solid " 251°	3.19
" " " " 200°	0.03
" " " " 165°	0.007
" " " " 100°	0.004
" " " " 100°	0.00002

Clean surfaces of lead and gold held together *in vacuo* at a temperature of only 40° for four days, united so firmly as to withstand a load equal to one-third of the breaking strain of lead itself before parting. Experiments are still in progress, and from them it would appear that the diffusibility of solid gold in solid silver, or copper, at 800°, is of the same order as that of gold in lead at 100°.

—A. W.

Zinc-Iron Ores, Magnetic Concentration; Wetherill System of. Eng. and Mining J. 1896, 61, 564-565.

Two electro-magnets are arranged with adjustable pole-pieces (fixed at any point by means of suitable nuts) at a convenient distance apart. The ore is fed in a $\frac{1}{2}$ to $\frac{3}{4}$ in. layer on to a belt from a hopper with adjustable feed. The belt travels towards and over a roller, bringing the fine ore particles within the sphere of attraction of the pole-pieces; the magnetic portion is attracted and is caught and carried on by another and a horizontal belt travelling away from the poles. The ore particles are thus carried off until they fall by gravity into a suitable receptacle. The non-magnetic particles fall into a second receptacle beneath. A proper adjustment of the current, of the space between the poles, and of the distance of the belt carrying the ore from the poles, causes the ore to be removed by the horizontal belt as fast as it is attracted by them. With a current of 6 amperes and 16 volts, such a machine with four pole-pieces separates Franklinite from Willemite, but requires to be passed three times through the apparatus to insure perfect separation, each passage being made at the rate of $3\frac{1}{2}$ tons per hour. For hematite, a yoke with two pole-pieces is used, with a current of 8 amperes and 22 volts. The machine for treating coarse particles is slightly modified. The process as in use in the Lehigh Zinc and Iron Co., removes garnet, Franklinite, tephroite, and Fowlerite from Willemite, zincite, and limonite, treating 1,000 tons of the mixture per mensem. The magnetic intensity of the machine being readily adjusted, several products may be obtained showing slight differences in magnetic permeability. The only substances in which iron is largely present that have not been attracted by the magnets constructed up to the present time, are the higher sulphides and "the cyanides of that metal." Magnets of greater power are being constructed, and it is expected that these substances will also be capable of magnetic separation.—W. G. M.

Aluminium, The Presence of Sodium in. Rev. de Chim. Ind. 1896, 7, [76], 107-108.

Besides carbon and nitrogen, the presence of which has been proved by Moissan, commercial aluminium nearly always contains sodium. 250 grams of aluminium filings were digested for 15 days in 300 c.c. of absolutely pure distilled water, and to avoid other possible sources of error, the filings were digested in an aluminium vessel. Every day the mixture was heated to boiling, and finally filtered and washed with boiling water. The liquid was slightly alkaline. It was evaporated in a platinum dish and ignited at a dull red heat. On the addition of HCl, carbonic acid was disengaged. After again evaporating and drying at 300°, the residue presented all the characteristics of sodium chloride. The quantity of Na thus extracted by water was determined by titration with silver nitrate. It was found to amount in different samples to from 0.1-0.3 per cent. In one sample prepared a considerable time, the sodium amounted to 0.42 per cent.

The presence of sodium in aluminium is very detrimental, since, in the presence of water, sodium hydrate is formed, in which the film of aluminium oxide (which always forms and serves as a protection to the metal against further oxidation) is dissolved. The quantity of soda present being very small, it may not be able to dissolve all the oxide formed; but the aluminate decomposes, liberating the sodium hydrate, which dissolves fresh portions, thereby increasing the alkalinity of the liquid, and, in proportion, its corroding action.

The properties of the alloys of aluminium depend on the purity of the metal employed, and also on the homogeneity of the alloy. An alloy of aluminium absolutely free from sodium, with 6 per cent. of tin, was not attacked by water with disengagement of gas, as stated by Riche. After two months, the metal was punctured in parts, with an efflorescence of alumina. But in presence of a considerable amount of tin, the decomposition is much stronger; hence tin solder for aluminium should be absolutely rejected.

The frequent want of homogeneity in the aluminium alloys, notably those also containing copper, is another great defect; for in such a case, in presence of moisture,

currents are set up, and the metal becomes oxidised. A sheet of aluminium which was kept in contact with water for several days became covered at certain points with an incrustation of alumina. On examining such parts under the microscope, a particle of carbon or some other foreign body was in most cases detected, which must have formed with the rest of the metal, a galvanic couple. In a solution of salt the action is much stronger, and takes place also in dilute alcohol. This accounts for the corrosion of the cans used by the military. With pure metal, free from nitrogen, carbon, and sodium, corrosion does not take place.—I. S.

Aluminium Alloys prepared by Chemical Reaction. C. Combes. Comptes rend. 122, [25], 1482-1484.

In place of the method recently proposed by Moissan (Comptes rend. 122, 1302) of combining powdered aluminium with metallic oxides in a bath of the molten metal, it is proposed to apply the metal from which the alloy is to be prepared, in the state of sulphide or chloride, to the fused aluminium, the result being a reduction to the metallic state and incorporation with the aluminium, whilst the sulphide or chloride of the latter metal simultaneously formed, can be collected and the metal recovered. In most cases the possibility of the reaction can be ascertained by reference to thermo-chemical data, the essential particular being a positive difference between the heat required for the formation of the metallic sulphide or chloride in question and that of the aluminium salt. For example, an alloy of nickel and aluminium can be so prepared, whereas zinc and manganese are not suitable. This rule hardly holds good, however, in the case of chlorides, since manganese can be alloyed with aluminium from the chloride of the former. One result of this reaction is the removal of a portion of the sodium frequently present in aluminium.

For nickel alloys, refined Bessemer nickel matte (NiS) is used. The alloy, containing 20 per cent. of nickel, is hard, and crystallises on cooling.

For manganese alloys, pieces of the chloride are dropped into the aluminium bath, and the chloride of the latter metal volatilises directly. The 4 per cent. (Mn) alloy exhibits a crystalline fracture.

In the case of chromium, the sesquichloride is employed, and the reaction is very violent. The 7 per cent. (Cr) alloy is very hard, and exhibits a fine crystalline structure, and the 13 per cent. alloy is perfectly crystalline, and can be powdered in a mortar.—C. S.

Gold Extraction by Potassium Cyanide. J. Loewy. Chem. Zeit. 1896, 20, [49], 479-480.

Working with a refractory cupriferous gold ore from the Lydenburg District (Transvaal), containing about 9 dwt. of gold per ton and 2.59 per cent. of copper, the author found that under similar conditions different cyanide solutions gave extractions as follows:—

Strength of Cyanide Solution.	Ag extracted.	Cu extracted.
Per Cent.	Per Cent.	Per Cent.
0.5	15.2	4.5
1.0	13.7	8.4
2.0	48.0	19.6
5.0	53.0	} over 25.0
10.0	76.5	

The results of all experiments tried may be summed up as follows:—

- (1.) The McArthur-Forrest recommendation to use only weak (0.2 to 1 per cent.) cyanide solutions for refractory ores, is not sound according to the author's opinion.
- (2.) Such weak solutions give an inferior extraction.
- (3.) The stronger the cyanide liquors, the greater is the amount both of base metals and of gold dissolved.
- (4.) The cyanide process is not suitable for most refractory ores, as the strength of cyanide required is too high, and the time needed for extraction too great.—W. G. M.

Gold Extraction: the Rignaud Process. Eng. and Mining J., 1896, 61, 561.

The ore or tailings are treated with the chloride of sulphur, S_2Cl_2 (see page 599), whereby chlorine is to be evolved and

the whole of the gold extracted. Taking the cost of tailings at 3 fr. per ton, and allowing 2 fr. for sinking fund, the total cost of the process is to be 9 fr. per ton.—W. G. M.

Gold Extraction, The Cassel-Hinman Bromine Process of. P. C. McIlhenny. J. Amer. Chem. Soc. 1896, **18**, [5], 451—456.

THIS process is intended for the extraction of low-grade ores, not suitable for amalgamation, as, for example, the telluride ores of Colorado. The *modus operandi* is practically the same as in the chlorination process. The ore is crushed, dried, sifted, roasted if necessary, and treated, either by percolation in vats, or, preferably, is agitated in revolving barrels, with an aqueous solution of bromine (strength, apparently about $1\frac{1}{2}$ per cent.). The liquid is then drawn off, the ore washed, &c. The chief and essential feature of the process is the subsequent recovery of the bromine, which is effected by adding bleaching powder, or potassium permanganate and sulphuric acid, to the liquor. The latter is then heated in a covered stone tank by direct steam. The bromine vapour is condensed in an earthenware worm, and there brought into contact with weak wash liquor from previous operations, for the purpose of regenerating bromine solution for future use. From a bath containing 15 lb. of bromine per 100 galls., the whole of the halogen is expelled, when 5 per cent. of the liquid has been distilled.

Important advantages are claimed for the process. As a solvent for gold, bromine is not only more rapid and thorough in its action than chlorine, but, on account of its superior solubility in water, may be used in stronger solutions, (up to 3 per cent.). Unlike chlorine, however, bromine attacks only to a slight extent the useless constituents (pyrites, &c.) of the ore, and the proportion converted into bromide little exceeds that corresponding to the gold dissolved. On this account the preliminary roasting of the ore (to destroy sulphides, &c.) need not be carried so far as is essential in the chlorination process; and this is a point of great importance, since certain ores—particularly tellurides of gold—lose a large proportion of the precious metal, either mechanically or by volatilisation, during the final stages of the roasting.—H. T. P.

Silver and Gold, Removal of, from Sea-Water by Mants-Metal Sheathing. A. Liversidge. Roy. Soc. of N. S. Wales, 1895.

COMPARING old Mants-metal plates which had been long exposed to the influence of sea-water with new specimens, the metallic portion showed an apparent loss of about half the silver and nearly one-third of the gold supposed to have been present originally; the scale upon the surface, whilst indicating about the same loss of silver, showed a gain of over 7 dwts. (or 700 per cent.) of gold. There is therefore a distinct loss of silver. The increase in the amount of gold may be accounted for, either by precipitation of the metal from the sea-water, or by the concentration, due to the solution of the other constituents of the sheathing, leaving the gold unattacked. Samples of new sheathing exposed for about 20 months to the influence of salt water showed a slight decrease in the amount of silver and an increase in that of gold; but the latter result is not satisfactory, as the gold contained platinum from the sulphuric acid used to dissolve the metal for analysis.—W. G. M.

Metallic Alloys, Fusibility of. H. Gautier. Comptes rend. 1896, **123**, 109.

THE melting point of alloys of tin and nickel, tin and aluminium, aluminium and silver, antimony and aluminium, were determined by means of Le Chatelier's thermo-electric couple. In each case the curves expressing the connection between melting point and percentage composition consist of three branches, thus pointing to the existence of definite compounds. The composition of these compounds is expressed by the formulae Ni_3Sn_2 , SnAl or Sn_2Al_3 , Ag_2Al , and SbAl .

The alloys of antimony and aluminium containing more than 2 per cent. of the latter metal are less fusible than aluminium. Antimony was found to melt at 632°, and not at 420°, which is the temperature usually given.—A. C. W.

Alloys, Metallic. H. Gautier. Comptes rend. 1896, **123**, 172—174.

IN continuation of his former paper (see preceding abstract), the author quotes a fourth case which may present itself in the solidification of alloys, *viz.*, where two non-isomorphous metals give a combination isomorphous with one of them, just as ammonium chloride and ferric chloride give a double compound isomorphous with the former. The study of the fusibility of the alloys should in this case throw light upon their constitution. Taking five pairs of metals, the effects upon the fusing point, of adding successive quantities of the less fusible metal to the other are as follows:—

Zinc-Silver.—The curve in this case runs in almost a straight line from 433° C. at 100 per cent. Zn up to 715° at 42 per cent. Zn; it then falls to 690° at 38 per cent. Zn, and finally rises almost in a straight line to 954° at 100 per cent. Ag.

Cadmium-Silver.—This curve rises evenly from 322° C. at 100 per cent. Cd to 710° at 58 per cent. Cd (which is higher than the mean of the constituents); thence it is less steep, but runs in a straight line up to 880° at 22·4 per cent. Cd; and thence assumes the form of a gradually flattening curve to 954°.

Tin-Silver.—The curve shows a fall from 232° at 100 per cent. Sn to 221° at 4·86 per cent. Ag; thence a nearly steady rise to 535° at 58·8 per cent. Ag, where the curve becomes gradually steeper up to 900° at 90·9 per cent. Ag; and, lastly, somewhat flatter up to 954°.

Copper-Nickel.—This would be a steadily flattening curve from 1,950° (pure Cu) up to 1,450° (pure Ni) but for a slight depression which finds its maximum at 1,340° for the 50 per cent. Ni alloy. The eutectic alloy, however, contains 0·5 per cent. Ni and melts at 1,945°; with this exception all the alloys of these metals have fusing points above the means of the constituent metals.

Antimony-Silver.—The fusing point is gradually lowered from 632° (pure Sb) to 482°, which is the eutectic alloy, and contains 55 per cent. Ag; thence it rises by a slightly S-shaped curve to the melting point of silver.

In these alloys, silver added to zinc or cadmium raises the fusing point above the mean; similarly, the melting point of tin or bismuth is raised by small quantities of antimony; and bismuth and antimony are isomorphous. This abnormal rise in the fusing point appears to be connected with isomorphism in alloys.—W. G. M.

Tungsten, Researches on. H. Moissan. Comptes rend. 1896, **123**, 14.

TUNGSTEN is readily obtained pure by reducing excess of tungstic acid with carbon in the electric furnace. If excess of carbon be used, or the metal fused so that it attacks the crucible, the carbide CW_6 is formed. Porous tungsten can be easily powdered, and at a temperature well below its melting point can be welded. It is more infusible than chromium and molybdenum, does not oxidise in moist air, but is slowly attacked by water containing carbon dioxide, reduces that gas at 1,200°, and is only attacked by acids (except a mixture of hydrofluoric and nitric) with difficulty. The carbide has very similar properties.—A. C. W.

PATENTS.

Refractory Ores [of Precious Metals], Impts. in Treating. A. J. Boulton, London. From P. A. Gasse, Paris. Eng. Pat. 12,692, July 1, 1895.

The refractory ore is suspended in water and agitated, air or oxygen containing about 5 to 7 per cent. of ozone being introduced through a pipe composed of unoxidisable material. The ozone is generated by passing dry and cooled oxygen or air through a chamber containing insulated metallic sheets, placed parallel with one another, and communicating alternately with the opposite poles of an intermittent or alternating current generator of high potential (7,000 volts). The ozone-laden gas is passed through water to absorb nitrogen acids, and then passes direct to the ore chamber, the intention being to oxidise the baser metals to oxides and sulphates, whilst leaving the "precious metals" in a refractory state, and thus better suited for separation from the former.—W. G. M.

Cyanide Process, Impts. in Treating Ores by, and in Appliances for. E. G. Appleby, London. From L. F. Gowans, Johannesburg. Eng. Pat. 14,162, July 25, 1895.

Two long, rectangular vats are built side by side, with a launder at one end placed at a level 12 in. below that of the discharge of the concentrator, and with accurately fitting discharge doors communicating with a second launder at the opposite end. The actual bottoms of the vats slope downwards toward the inlet end, but there is a perforated false bottom, covered with a filtering medium, which is placed horizontally. Running longitudinally over the vats, are a 6-in. water-pipe and a 9-in. air-main, each communicating with several series of perforated pipes suspended at any desired level in the vats. Within the air-main is a steam-coil, to heat the air supply when necessary. In use, water is admitted to the height of 1 ft. above the false bottom; air is next passed through one set of perforated pipes to agitate the liquid; the ore is then allowed to enter, more and more air being passed during the process in order to distribute it evenly. The water is pumped out from below, the cyanide solution being introduced, and in turn pumped away for further treatment, whilst the tailings are finally discharged through the end doors, with the aid of the agitation produced by the admission of water and air through the perforated pipes.—W. G. M.

Gold-extracting Processes [Chloride of Sulphur] and Apparatus therefor, Impts. in. W. P. Thompson, London. From La Soc. pour l'Extraction Intégrale et Economique de l'Or, Procédé de Rigaud, Paris. Eng. Pat. 15,954, Aug. 24, 1895.

The powdered ore is treated in a closed vessel with chloride of sulphur; the mixture is warmed and agitated. It is stated that only one clearly defined chloride of sulphur exists and that of the formula S_2Cl_2 , and this it is which is here referred to. The gold dissolves as chloride, and is recovered by precipitation; the other metals form insoluble compounds, which may be readily separated. The precipitant proposed is ferrous sulphate.—W. G. M.

Antimony Gold-bearing Ores, Improved Method of Treating. A. Jones, Melbourne. Eng. Pat. 10,097, May 12, 1896.

The powdered ore is treated with hydrochloric acid in a closed vat provided internally with a steam-coil for heating purposes, and with a rotary stirrer actuated from without; the hydrogen sulphide generated, is collected in a tank of water placed above the vat. When the acid is saturated with antimony, the solution is run off through an asbestos filtering box to an electrolysing vat, in which the antimony is deposited on suitable cathodes opposed to insoluble anodes; the chlorine produced by electrolysis is conveyed to the hydrogen sulphide tank, where it reacts with the latter substance, forming precipitated sulphur and hydrochloric acid, which may be used to treat a second batch of ore. The electrolysed solution is also returned by means of a pump to the dissolving vat. The ore, freed in this

manner from antimony, still retains the whole of the gold, and for further treatment is removed from the vat through a man-hole provided at the bottom.—W. G. M.

Reed Wire; Impt. in Means of Cleaning, Galvanising, and Hardening or Tempering, to prevent Rust and Wear. S. Stankie, Walsden, Lancashire. Eng. Pat. 12,908, July 4, 1895.

The wire is unwound from the reed-maker's flanged pulley and passed consecutively through an acid bath for cleansing, a metal bath for galvanising, an asbestos-lined clip to remove superfluous liquid metal, and finally over a revolving pulley through water to "temper" it, and thence it is wound on to a tin wheel.—W. G. M.

Puddling and Reheating Furnaces of the Siemens Type, Impts. in. E. Bonchill, Marchienne-au-Pont, Belgium. Eng. Pat. 15,701, Aug. 20, 1895.

These are (1) the provision of a valve adapted to serve specially in connection with each gas producer, and provided with its own independent operating lever, in order that any one producer may be thrown out of work without interfering with the others; (2) cooling the basin of the furnace by causing the required amount of external air to pass under them, such air being drawn in by the natural draught of the furnace; (3) causing the burnt gases to pass through comparatively long flues before they enter the regenerators, so that they may deposit suspended matters, and at the same time be partially cooled, whereby they are prevented from too quickly destroying the brickwork of the regenerators.—A. G. B.

Chlorine and Zinc, Impts. in and connected with the Production of. F. M. Lyte, London. Eng. Pat. 15,813, Aug. 22, 1895.

See under VII., page 595.

Double Aluminium Sulphides or Sulphurets with Alkaline Metals, or Metals of the Nature of Alkaline Earths; A Process for the Production of [Aluminium Manufacture]. D. Péniaikoff, Pierre Huy, Belgium. Eng. Pat. 6290, March 21, 1895. (Under Internat. Convention.)

When alumina is highly heated in vapour of carbon bisulphide, the reaction whereby aluminium sulphide is formed takes place with difficulty, owing to the absorption of heat. But the conditions are in this respect reversed by introduction of a body, such as potassium oxide, which in reacting with carbon bisulphide evolves much heat. Thus, by using a "triple base aluminate," the reaction is shown to become exothermic or heat-generating. In practice, an aluminate is obtained "by treating red bauxite and alkaline sulphate, mixed with iron pyrites or alkaline sulphide," and the aluminate is mixed with tar, carbonised, and then subjected in small fragments to the action of the vapours of sulphur, carbon oxy-sulphide or bisulphide, to obtain (according to the proportion of carbon present) either a baked or a melted product. From the baked product, aluminium or aluminium alloys may be obtained by the action of reducing gases, and from the fused product, by electrolysis.—E. S.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A).—ELECTRO-CHEMISTRY.

Lead Accumulators, Theory of. C. Liebenow. Zeits. für Elektrochem. 1896, 2, 30, 653, 655.

In a previous paper the author has shown that the reactions in a lead accumulator can be more simply described if we assume that negative PbO_2 -ions are present; but hitherto the existence of such ions has not been proved.

Consider an aqueous solution of the compound $Pb(KO)_2$. If it is to be regarded as a solution of the double oxide PbO, K_2O , it ought to split up into ions in accordance with the equation—

but, if it is to be regarded as a solution of lead plumbate, it ought to split up into ions according to the equation—

Which view is correct may be tested as follows:—A dilute solution of caustic potash is electrolysed between platinum electrodes (wires) in a glass cylinder divided by suitable membranes into three parts. The solution in the middle part is saturated with lead oxide; the parts on either side contain only potash. When a current is passed, oxygen is evolved at the anode and hydrogen at the cathode. At the same time all positive ions in the electrolyte move towards the negative electrode and all negative ions towards the positive electrode. If the lead only gives rise to positive metallic ions (equation 1.), it will move with the sodium ions in the direction of the current; but if it gives rise to negative PbO_2 -ions (equation 11.), these will move in a direction opposite to that of the current. The author finds that the latter is what actually takes place, and regards this as conclusive proof of the existence of negative PbO_2 -ions.

Electrolysing Apparatus, An Impd. [Bi-polar Electrodes.] J. Kolb and A. D. A. Lambert, Lille, France. Eng. Pat. 14,342, July 27, 1895.

THE electrolyser consists of two series of plates of insulating material—say ebonite; one series is provided with conducting blades which form bi-polar electrodes, and the other, which is interposed between the above, has porous extensions. All these plates are recessed on both sides, so that when placed together, they form compartments for the circulation of the electrolyte. Ribs are arranged on the inner surface of the recesses on each plate so that they come against each other without making contact. Each plate is provided with four openings which, in the case of the electrode plates, are closed with thin metal blades of about $\frac{1}{20}$ th mm. in thickness, the two faces of which are of opposite polarity; while in the intermediate plates the conducting blades are replaced by porous plates. The blades and plates are held in front of the apertures in the insulating plates by frames and ebonite pegs, and there are channels in the thickness of the plates carrying electrodes, the lower of which admit, while the upper discharge the electrolyte. These channels, which are connected with a main conduit, are so arranged that the liquid entering at one side of the apparatus, leaves it at the other, whilst two apertures at the top of each plate form continuous channels for the collection and removal of the gases when the plates are in juxtaposition, and similarly formed channels at the bottom of the plates serve to admit air under pressure, when necessary. By means of these two systems of channels, both the liquid and gaseous products of electrolysis are separated. The plates are clamped together in suitable frames, from which they are insulated, and electrical connection is made with the four metal blades on each of the terminal electrodes.—G. H. R.

Electric Accumulators [“Dry” Alkaline], Impts. in. E. W. Jungner, Skara, Sweden. Eng. Pat. 15,880, Aug. 23, 1895.

THESE improvements relate to the construction of an alkaline secondary battery of the “dry” kind. Cotton or asbestos saturated with zincate of potash for electrolyte, with an oxygen-absorbing metallic powder next the anode in charging—finely-divided silver, mercury, or an amalgam of silver and mercury being claimed, copper also being mentioned in the specification. The inventor claims a method of sup-

porting the oxides in a bag (asbestos), mixing the metallic powder with graphite, and sealing the cell with a layer of sand and pitch to exclude carbon dioxide.—J. C. R.

Electric Accumulators [Celluloid Plates], Impts. in. P. F. Ribbe, Berlin. Eng. Pat. 5506, March 11, 1896.

THIS invention is based on the use of carrying-plates of celluloid, which plates, after a thin lead plate has been placed between, are connected by means of a celluloid solution. The celluloid plates are so pressed or stamped that they are directly connected at suitable places by the celluloid solution. The celluloid plates thus enclose the lead plates, and are provided with a number of openings, the edges of which form the supports for the active material or paste. The invention is illustrated by drawings.

—J. C. R.

Electric Batteries, Impts. in [Primary]. J. Entwistle, Manchester. From S. N. Smith and E. S. Baring-Gould, Minnesota, U.S.A. Eng. Pat. 6981, March 31, 1896.

THE battery consists of an outer vessel within which is fixed a porous pot. Between this and the outer vessel the zinc, in the form of an incomplete cylinder, is suspended from the lid, and through an opening in it is passed a cup of porous carbon which constitutes the other element. The outer vessel contains a solution of common salt, whilst in the porous pot is placed a depolarising solution made by diluting one to three parts of sulphuric acid with three parts of water, to which, when cold, is added nitrate of soda in the proportion of 8 to 10 oz. of the nitrate to 1 lb. of the acid. The carbon pot is closed by a lid provided with a washer, and connection is made with the lower part of the zinc to prevent unequal action.—G. H. R.

(B.)—ELECTRO-METALLURGY.

Electrolytic Separation and Refining of Metals, Process for. D. Tommasi, Monteur Scient., July 1896, 10, 507—508.

THE anodes are either cast plates or granulated material resting in direct contact with the positive leads. The cathode is a vertical disc capable of rotation about its horizontal axis. Only the lower portion is immersed in the electrolyte, and the upper part is passed during rotation between scrapers that effect the removal of any spongy deposit, transferring it to channels by which it is conveyed to a convenient receptacle. The disc is constructed in replaceable sectors, when a reguline deposit is to be obtained, and the sectors are one by one removed mechanically as they attain sufficient thickness, and are plunged beneath a fluid bath of the metal under treatment until the deposit has been melted away and the sector is ready for use again. A solid disc is preferred for spongy deposits. The advantages of this arrangement are that polarisation is prevented by the rotation of the cathode and by the action of the scrapers, and the liquid is sufficiently agitated to prevent separation into layers of different density, whilst spongy deposits are removed as fast as they are produced, thus preventing oxidation by the liquid and the occurrence of local action. At the same time the electrodes may be allowed to approach more closely owing to the impossibility of short-circuiting through irregularity of deposit, and the resistance of the bath is therefore sensibly diminished.

—W. G. M.

PATENTS.

Electrolytic Deposition of Metals, Impts. in the, and in means applicable therefor [Compound Cathode]. C. Kalkigh, Johannesburg, Africa. Eng. Pat. 11,944, June 1, 1895.

THE electrodes are constructed of two or more layers of the same or of different metals, or of a substance having a metallic surface temporarily attached, the object being to facilitate the separation of the deposited metal. In the case of the deposition of gold, lead cathodes, the surface of which has been gilded electrolytically, may be employed, and this surface is covered with lead-foil, which receives the deposit of gold. The lead-foil is removed from its backing and placed on an inclined sheet of screening, or metal

plate, and heated above the melting point of the lead, which runs off, leaving the film of gold. Any suitable metal having a melting point sufficiently different from that of the deposited metal, may be used. With cyanide solutions the electrodes are plates of copper, silver, or other metal, or may take the form described in Eng. Pat. 23,431, 1893 (this Journal, 1894, 402), but their surfaces must be plated with silver or gold, and be kept saturated with mercury sprayed on them in a finely divided state. To secure better deposition, a salt of a base metal, preferably mercury, is added to the solution in excess of the gold; or silver-foil, which will form a salt in solution, may be employed. The excess of mercury drips off the cathode, carrying with it the gold before it has time to get attached to the copper. The used electrolyte is run through copper turnings to free it from the mercury salt. It is preferable to frequently reverse the current so that deposition takes place on both electrodes, but an alternating-current dynamo may be used. The deposition of other metals is also improved by the addition to the electrolyte of the salt of a second metal the electro-chemical energy of which is lower than that of the metal to be deposited, but with lead cathodes the salt of mercury is inadmissible.—G. H. R.

Gold and Silver Extracting [Ramic Diaphragm], from Cyanide Solutions by Electricity; Impts. in or connected with Apparatus for. J. Pflger, Kaiserslautern, Germany. Eng. Pat. 16,736, Sept. 6, 1895.

THE inventor claims a porous diaphragm, made of ramie fibre, in apparatus for extracting gold and silver from cyanide solutions by electricity, with or without soaking the said diaphragm in a solution of caustic alkali.—J. C. R.

Gold and Silver Extracting, from Cyanide Solutions, Electrical Apparatus for; Impts. in or connected with. J. Pflger, Kaiserslautern, Germany. Eng. Pat. 16,737, Sept. 6, 1895.

THE essential feature is in employing a cathode of large surface in precipitating gold electrolytically, or by zinc, short-circuited, battery-fashion. The cathode is made of shavings, wire-work, or gauze (iron). The electrolyte circulates through the cathode. The gold may be separated from the cathode by mercury, or cyanide of potassium solution (8 to 10 per cent.), a carbon plate being joined up to the cathode to form a couple.—J. C. R.

Nickel Plating, Impts. in Process of [Corrugated Anodes]. H. L. Haas, New York, U.S.A. Eng. Pat. 7358, April 7, 1896.

CORRUGATED nickel anodes are employed, whereby it is claimed that the strength of the bath is maintained, as the solution of the anode by the sulphuric acid formed on the passage of the current through the neutral solution, takes place uniformly with deposition of the metal at the cathode. The large anode surface also admits of the use of a power as low as 2 volts; and the formation of basic salts of nickel and the stripping of the deposit due to the action of an excess of hydrogen at the cathode, which are the results of a high voltage, are prevented.

—G. H. R.

XII.—FATS, OILS, AND SOAP.

Fatty Acids, Salts of, and Soaps; Behaviour of, in Presence of Water. F. Kraft and A. Strutz. Ber. 29, [8], 1896, 1328—1334. (Compare this Journal, 1894, 1207; and 1896, 206.)

IN the last communication on the above subject, Kraft and Wiglow showed that it was impossible to determine the molecular weights of the real soaps in aqueous solution by the ebullioscopic method, and that such solutions behaved in all respects like *colloids*. It is well known that alcoholic solutions of soaps exhibit a neutral reaction towards indicators, showing that they are not decomposed, as is the case with aqueous solutions; hence the authors have applied the ebullioscopic method to the determination of the molecular weight of sodium oleate (chosen on account of its greater solubility) in alcoholic solution, and found that

it corresponds very closely to that required by the formula $2C_{18}H_{35}O_2Na$. The authors have also, for the sake of comparison, extended their experiments to hexadecyl ammonium chloride ($C_{16}H_{33}NH_3Cl$), which is a salt of an organic base with an inorganic acid, whilst the soaps are salts of inorganic bases with organic acids, and found that this substance behaves in precisely the same way as the soaps, *viz.*, in aqueous solution it exhibits the properties of a *colloid*, *i.e.*, it does not raise the boiling point of the solvent, whilst in alcoholic solution it behaves as a *crystalloid*, and gives a molecular weight of 291, corresponding to the theoretical number 277. That sodium oleate possesses a molecular weight twice that of the theoretical is comparable with the fact that, besides the neutral salts of the fatty acids, acid salts are also known, such as potassium diacetate, $C_2H_3O_2K$, $C_2H_3O_2$, &c. On the other hand, acid salts of ammonium chloride have never been discovered. The analogy between the soaps and the homologous series of which hexadecyl ammonium chloride is a member, is complete. In the case of aqueous solutions of the soaps, the lower members, *e.g.*, sodium acetate, are *crystalloids*, whilst the higher members are *colloids*; and the same holds good for the hexadecyl ammonium chloride series, the lowest members, *viz.*, ammonium chloride and methyl ammonium chloride, being *crystalloids*.—J. S.

Colloidal Solutions, A Theory of. F. Krafft. Ber. 29, 1896, [8], 1334—1341.

THE author discusses the work which he, in conjunction with others (see preceding abstract), has carried out on the nature of soap solutions, and arrives at the following conclusions:—

1. Colloidal liquids or solutions contain the liquefied substances in the molecular condition; and
2. Colloidal liquefied molecules rotate in very small closed paths or surfaces.—J. S.

Oil-Presses, Impts. in or appertaining to. G. C. Dymond. Liverpool. From K. Eisenwerke, Harburg, Hamburg. Eng. Pat. 13,623, July 16, 1895.

THESE consist in an oil-press with revoluble earthenware press-pots, in combination with a seal-heater, charging hopper, and hydraulic preliminary and final pressing apparatus, arranged in such a manner that the axis of one pot coincides with the axes of the heater and the press, whilst the axis of the other pot coincides with the axes of the preliminary pressing apparatus. To increase the production of oil, the preliminary pressing apparatus (by changing the pressure) is used as high-pressure, and the main press as low-pressure apparatus, the first partly pressing out the oil, and the second completing the operation without removing the material from the press-pot in the interval.—J. J. K.

Soap, Impts. in the Manufacture of. R. E. Green, London. Eng. Pat. 18,163, Sept. 28, 1895.

AN insoluble soap is first made by combining, with the aid of steam, fatty matter with any of the hydrates of barium, calcium, magnesium, aluminium, or with lead oxide. The liberated glycerin is separated by pressure. The insoluble soap is then converted into a soluble one by boiling with sodium silicate (if a hard laundry soap be desired) or sodium phosphate (if a neutral soap be required). Sodium

chloride is added to separate the soluble soap from the insoluble silicate or phosphate of the alkaline earth, and, after settling, the soap is drawn off for a final melting before it is run into the frames. The insoluble residue is said to be useful for the manufacture of paint.—J. J. K.

PATENT.

Treating Skins [Sulphide of Sodium], Impts. in the Art or Process of. J. W. Pearson and F. A. T. Moor, both of Philadelphia (Penn.), U.S.A. Eng. Pat. 3715, Feb. 18, 1896.

THE inventors claim the preparation of skins or hides, ready for "any preferred method of tanning," by a single, continuous, and uninterrupted operation of a few hours' duration.

The process consists in subjecting skins and hides to the action of a solution of sodium sulphide in a closed vessel. The solution at first, has (or may have) a temperature of about 100° F.; and, during the first two hours, the containing vessel or drum is rotated, whilst, during the next ten hours, it remains at rest. The drum is then opened and the skins taken out and washed. They are then ready for tanning.

25 lb. of sodium sulphide are dissolved in 20 "ordinary buckets full" of water, this solution being sufficient for the treatment of 240 sheep-skins.

The "skins or hides" are placed in the solution "just as they come from the animal, except in the case of sheep-skins, when the wool is previously removed."—E. R. B.

XV.—MANURES, Etc.

Excessive Manuring in Spain. U.S. Consular Reps., July 1896, 591.

UNDER date of June 18, 1896, Consul-General Bowen, of Barcelona, transmits the annual report from Consular Agent Mertens, of Grao, from which the following statement relative to the indiscriminate use of fertilisers in Valencia is extracted:—

While the exports from Grao during the year 1895 were largely in excess of those of the preceding year, as far as tonnage is concerned, the profits did not keep pace with this increase. This was chiefly due to the indiscriminate use of artificial manures, which the farmers of this province have employed during the last few years in their fields to obtain a larger quantity of fruit and other produce. The result has been that the quality of oranges is, in many cases, such that they could not stand exportation, and arrived at their destination in a completely spoiled condition. The complaints from the rice millers are to the same effect, and the low prices of this grain, due to this deterioration in quality, proves a veritable calamity. The desire to secure larger crops was, in many instances, such that some farmers went beyond employing an increased quantity of guano, and used sulphates of ammonia and nitrates of soda alone as manure, without any other preparation or mixture with other chemicals. The effect on the soil must, sooner or later, prove disastrous, and the result will be complete failure of crops, likely to last for several years. American farmers should take warning from this, and use artificial manures carefully and judiciously.

Fertiliser, Ground Mineral Phosphate as a. F. T. Shutt. Chem. News, 1896, 74, 4.

THE author found that by treatment of finely ground mineral phosphate (apatite), containing about 25 per cent. of carbonate of lime, with a 1 per cent. citric acid solution, only 6.2 per cent. of the total phosphoric acid was rendered soluble, or 1.5 per cent. of phosphoric acid passed into solution. Experiments were undertaken with the object of rendering the phosphoric acid soluble. The results of the first series of experiments were published in the Report of the Minister of Agriculture for 1893. It was found in one instance that fusion of the finely ground apatite with bisulphate of soda rendered phosphoric acid equivalent to 38.49 per cent. of the apatite, soluble. In the above-mentioned report the author draws the following conclusions from his first series of experiments:—Any soluble phosphoric acid formed by ignition of the mineral phosphate with sodium or potassium sulphate immediately re-combines in presence of water to form tricalcium phosphate. The ignition of mineral phosphates with sodium or potassium bisulphate produces, according to circumstances, more or less soluble phosphoric acid.

Since the issue of this report the author has undertaken a further series of experiments, but he states that these were made before the publication of Dr. Dyer's paper (this Journal, 1894, 13, 288), wherein it is said that 1 per cent. citric acid solution represents the acidity in root-sap, and he used 2 per cent. citric acid solution to ascertain the soluble phosphoric acid.

The finely ground mineral phosphate was ignited with sulphate of soda, with the result that phosphoric acid

equivalent to from 35 to 37 per cent. of the phosphate was soluble in the citric acid solution.

Ignition of the finely ground apatite with a crude product consisting for the most part of sulphate, but containing a small proportion of bisulphate of soda, rendered 50 per cent. soluble in the citric acid solution.

Ignition of the finely ground phosphate with either wood ashes or a mixture of wood ashes and sand did not appreciably increase the solubility.

The finely ground phosphate was fused with potassium carbonate, and the mass treated with water. This dissolved phosphoric acid equivalent to 6.5 per cent. of the phosphate. Treatment of the residue in the cold with 1 per cent. citric acid solution further dissolved phosphoric acid equivalent to 4.3 per cent. of the phosphate.

The author points out that if the potash salt be used in the fusion, a better fertiliser is obtained on account of the potash introduced.—A. S.

Animals' Carcasses and Offal, Imps. in Apparatus for Treating. H. C. F. Otte, Altona, Germany. Eng. Pat. 8990, May 6, 1895.

The apparatus consists of a rotating perforated drum with a steam-jacketed pan. The offal, &c., is first heated by the steam jacket and afterwards by the direct injection of "live steam."—E. R. B.

XVI.—SUGAR, STARCH, GUM, Etc.

Sugar-House Analyses, Two Sources of Error in. E. C. Shorey. J. Amer. Chem. Soc. 1896, 18, [5], 462—465.

1. *The Determination of Fibre (Insoluble Matter) in Cane and Bagasse* is usually made by extracting with water and weighing the dried residue. It is shown that discordant results are likely to be obtained if the duration of boiling and the number of washings with water be varied. For instance, fibre prepared by exhausting cane with cold water, yielded up to boiling water 7.2 per cent. of its weight in five minutes, 12 per cent. in two hours. A uniform *modus operandi* therefore should be adopted in respect to time of boiling, state of sub-division of the sample, &c. When the sole object of an analysis is merely to compare the percentages of fibre in the cane and bagasse respectively, with a view to calculating the "extraction" by formula, the author prefers to dry and regard as "fibre" the residue from the alcoholic extraction of the cane, since the results are more uniform, and readily obtained.

2. *Determination of Albuminoid Nitrogen.*—In the generally accepted method, the cane juice is heated to boiling, treated with cupric hydrate, allowed to cool, filtered, and nitrogen determined in the precipitate. The results thus obtained are considerably too low, owing to the conversion, at a boiling temperature, of a portion of the albumin into other bodies (probably peptones)—not precipitated by copper hydrate—under the influence of the natural acidity of the juice. In two experiments, the loss of albuminoid nitrogen incurred by boiling the juice for one minute was found to be 9 per cent. and 16 per cent. respectively (total N = 100). It is recommended, therefore, to add copper hydrate to the cold juice, to filter cold and wash with cold water.—H. T. P.

Sugar Industry, Progress in, for the First Quarter of 1896. Dingl. Polyt. J. 1896, 300, 253—264.

The Simultaneous Determination of the Organic and Mineral Acidity of Beetroot Juice.—Sidersky (J. des Fabricants de

Sucre, 1896, 37, No. 3) recommends for this purpose the use of paper soaked in an aqueous solution (1:1000) of Congo Red, 4 R. A drop of dilute mineral acid produces a dark brown stain on the paper, whilst organic acids are without effect. If a known volume of beetroot juice be treated with alkali, the stain becomes less intense in proportion as the mineral acid is neutralised; the absence of colour on the test paper is an indication that organic acids alone are present. The same author has discovered that the colouring matter present in the beetroot is a more sensitive indicator. Beet juice oxidises rapidly in the air, thereby occasioning the black colour of diffusion juice. The addition of sulphuric acid prevents this oxidation and causes the acid distillery liquor to appear clear and bright. If potash of known titre be gradually run into a measured quantity of such juice, a sudden darkening occurs. This vanishes on shaking, so long as the juice contains free sulphuric acid; when this is neutralised, the oxidation and change of colour at once sets in, and some colouring matter is precipitated. More potash is added until the liquor is neutral to litmus paper. The end of the first reaction indicates the free mineral acid, and the second the total acidity; the difference between them is the acidity due to organic acids.

Grundmann, in some experiments on diffusion (Centralblatt f. die Zuckerind. der Welt, 1896, 4, 419), states that in most factories the sugar content of the thin juice was lower than that of the diffusion juice; he suggests that the slicings, before being mashed with battery juice, should be subjected to a previous diffusion with thin juice. The writer of the review suggests the following method of working:—When the diffuser is filled with slicings, these are mashed with thin juice at a temperature of 80° C., introduced from below by a conduit, so that the slicing and mashing take place whilst the juice from the previous diffuser is being discharged for defection. As soon as this operation is over the fresh diffuser is filled and mashed as before with battery juice, and the resulting thin juice passed into a special measuring vessel. When, after mashing, the thin juice has left the diffuser, the diffusion juice which is about to enter is passed by means of valves through another measuring vessel to the first defection, and when purified, serves for mashing in the succeeding diffusers. The thin juice derived from the previous diffusion contained in the first measurer passes to the second defection, and can be there treated with a small quantity of lime and saturated up to 0.03 per cent. of alkalinity in order to be ready for further working.

The electrical purification of juice has made little advance since the opposition offered to it three years ago. It is not generally known to what extent Schollmeyer's method is employed in Germany. According to Jauraux, Gallois, and Dupont (Gazeta Żukrowicza, 1895, 16, through Zeits. für Zuckerind. in Böhmen, 1896, 20, 252), lime or baryta is added to the juice from the beetroot or sugar cane until there is a slight alkaline reaction. It is heated from 85—90° C., filtered, and electrolysed in two series of vessels; the first being on a higher level, so that the juice can flow into the second. The first vessel is divided by two porous porcelain plates into three compartments; the middle one containing the defeccated juice and the two outer, water. The cathode, either of manganese or aluminium oxide, is lowered into the juice, whilst the anodes, prepared of carbon, iron, or other material insoluble in alkali, are placed in the water. Acids are liberated by the electrolysis from the cathode and combine with the same; the alkali diffuses through the porcelain plates into the water. The juice then flows into the second vessel, where complete purification is effected by means of lead electrodes. When the electrolysis is finished, the juice is run off and the precipitated organic compounds and lead salts are removed by filtration. Should the juice still contain traces of lead, they can be removed by rendering slightly acid with phosphoric acid, the excess of the latter being adjusted by lime. Little is known of this process, which, if generally employed, would revolutionise the purification of juice. One refinery, however, which has employed this or a similar method (Neue Zeits. f. Rübenzuckerind. 1895, 36, 19), finds that the lead anodes become covered with an insoluble precipitate, consisting for the most part of lead oxide, with which

apparently the organic acids are too weak to combine, and the working is thereby hindered.

Temporary unsatisfactory working of the defecation-mud presses frequently occurs, and arises from various causes—among others, cholesterin, which is derived from the beet root, and imparts a greasiness to the mud. The question has been discussed by the Brunswick-Hanoverian *Zuckerzeits.*, and Brüning (*Zeits. Ver. Rübenzuckerind.* 1896, **46**, 71) is of opinion that the difficulty in filtration arises from overheating during the diffusion. Herzfeld, who has examined the mud, found that it contained a considerable amount of iron, which combines with the pectins to form gelatinous compounds instead of the granular calcium salt of the pectin. He thereupon conjectured the cause of the difficulty in filtration to be that a considerable amount of pectin enters the juice during overheating; and in consequence of limestone being used, the iron present therein contributed to the formation of an iron compound of the pectin. When, therefore, Brüning only warmed to 75° C., the filter presses worked satisfactorily. Herzfeld also remarks that difficult working with thick juice presses is nearly always to be attributed to the presence of too much fat. A case is cited in which a mud was acid to phenolphthalein, alkaline to litmus, and contained a considerable amount of free alumina arising from the decomposition of aluminates by carbonic acid during saturation. This delayed deposition and made filtration through cloths impossible. On adding a small quantity of lime, the quality of the mud was immediately changed—it settled easily and filtered normally. It is therefore unnecessary, when material is rich in alumina, to carry saturation to the extent at one time considered requisite.—J. L. B.

Sugar Industry, Progress in, for the First Quarter of 1896. Dingl. Polyt. J., 1896, **300**, 282—287, 296—301.

Dry and Wet Defecation.—J. Murke (*Die Deutsche Zuckerind.* 1895, **20**, 1874) concludes from his experiments that in many cases wet defecation is to be preferred to dry. The darkening of the juice treated in the dry way might be somewhat lessened by diluting the juice prior to treatment, but then the chief advantage of dry defecation over wet, namely, the smaller quantity of water to be evaporated, would not be realised. On the other hand, it is generally advantageous to employ the dry process with beetroot material, this showing little or no difference in the final result, when the two methods are tested side by side.

Treatment of Calcium Saccharate in Filter Presses, Washing Out, and Shudging the Saccharate with Water, Lime-Water, or Solutions of Sugar and Saccharate Saturated or Supersaturated with Lime.—P. Bengtson Harje (*ibid.* 1896, **21**, 238) found that if calcium tri-saccharate be treated with water or lime-water, it is decomposed the more readily the higher the temperature of the wash water. Solutions of calcium mono- or disaccharate result, or the sugar is split off, in all cases with separation of calcium hydroxide. In practice this decomposition gives rise to the formation of channels in the press cakes during washing in the filter presses, through which the water flows off without fulfilling its purpose. The solution of the saccharate with attendant phenomena, are wholly prevented by the application of a previously prepared washing liquid, consisting of sugar or saccharate solutions, saturated or supersaturated with lime, which are without action on the saccharate. These washing liquids, the use of which is patented, have generally a composition of 0.1 to 1 per cent. of sugar, and 0.4 to 0.65 per cent. of CaO, and are prepared by adding an excess of powdered lime to a 0.3 to 0.5 per cent. sugar or saccharate solution. The excess of lime is afterwards removed by filtration, or the clear liquid is decanted from the lime. By washing with such a liquid, the formation of channels and clefts in the cake is avoided, little time is required, the filter-cloths remain soft, and the colouring matters and salts are completely removed. A saccharate washed in this manner yields after saturation a good, clear, sweet juice, the massecuite from which can be immediately employed for the production of finished sugar.

Hudec (*Oester. Ungar. Zeits. für Zuckerind. und Landwirts.* 1896, **25**, 38) gives a description of the separa-

tion of ammonia, by the Sixta-Hudec method, from the steam rising from the juice during evaporation—a process employed in a sugar factory during the last campaign. The ammonia is removed from the steam of the juice to prevent its action on the heating area of the succeeding member of the triple effect, by spraying a solution of potash alum into it. Experiments showed that the solution of alum does not exert an unfavourable influence on the evaporation. The alumina formed is pure and white, and the salts from the decomposition contained 12 to 16.25 per cent. of ammonia. Isolated groups of crystals were found in the mass of salt, containing as much as 24 per cent. of ammonia. The author calculates a profit of 4.62 fl. per cwt. of alum employed.

At the beginning of the present campaign, Drenkman *Zeits. Ver. Rübenzuckerind.* 1896, **6**, 81) noticed that the juices were frequently dark in colour after defecation, saturation, and boiling, and that this coloration became more frequent and regular when the beets had been stored for some time. This phenomenon is due, not to the colouring matters contained in the beet, but to the products of decomposition of glucose, apoglucinic acid, and saccharic acid. The author has also observed during evaporation a striking increase of alkalinity, which is mainly attributed to the presence of ammonia in the juices. The additional alkalinity is favorable to the colouring of the juice, for during the warming, the organic acids combine with a small quantity of iron, and under the influence of light become dark violet coloured. It seems that when glucose is boiled with lime or alkali, acids are formed, and it is noticeable that beets yielding dark syrups contain considerable quantities of reducing substances. The dark juices influence only the colour of the first products, and not the yield. The reason of the greater viscosity so often observed in the boiled after-products, is not so much the concentration of the dark organic acids as the excess of arabic acid, the deleterious effect of which on the crystallisation of sugar is considerably intensified by the increased alkalinity of the juice. It is therefore better to keep the alkalinity of after-products low, and the boiled mass in a state of motion.

Cane Sugar.—The propagation of the sugar cane is usually effected in all tropical countries by means of small shoots removed from the stem at the time of harvest. These, when planted, quickly develop "eyes," and at the end of the year have become full-grown plants ready for gathering. J. Waaker (*Botanisches Centralblatt*, 1896, **17**, 37), has succeeded in obtaining seed from the cane and in raising flourishing plants therefrom. He has not, however, met with the same degree of success with all species of the cane, some of the varieties having proved particularly ill-adapted for the production of seed.

Organic Non-Sugar in Cane Juice.—According to Maxwell (*Deutsch. Zuckerind.* 1896, **21**, 425 *et seq.*), the organic non-sugar, free from nitrogen, constitutes the gums, the chief impurity met with in the factory. Three groups of substances have been isolated from the gum, all of which are composed of glucose-forming constituents combined with a more or less insoluble modification of cellulose. Further investigations have shown that this is a mixture of mucilage and gum. The mucilage consists for the most part of hexosans, which are decomposed into glucose and cellulose by boiling with dilute acids (see Maxwell, this *Journal*, 1896, 125). The true gums are composed of pentosans, and on hydrolysis yield pentoses. Lime is the only substance capable of removing these gums from the juice. The electric current has exercised a favourable influence on the juice, for, although unaccompanied by any purifying effect, the boiling is rendered more satisfactory and the grain forms at once.—J. L. B.

Masseculite, Investigations relating to. Claassen.

Pap. Sac. Belge, **23**, 145.

It is desirable to determine the degree of concentration the composition of the syrup surrounding the crystals, and the amount of the crystals contained in the mass at different periods of the process, and for this purpose samples are taken before, during, and after the formation of "grain." The assay samples are polarised, and the amount of water they contain is determined. In order to calculate the

amount of crystals present, Schneider's formula is made use of:—Percentage of crystals = $100 \frac{P-n}{100-p}$, in which P = polarimetric reading of the massecuite, and p = that of the syrup. Finally, the amount of sugar dissolved in one part of water is calculated for each of the syrups, and this number is compared with that given by Herzfeld for

solutions of pure sugar. If a represent the quantity of sugar dissolved in one part of water in the syrup under examination, and b the quantity of sugar contained in a solution of pure sugar, then $\frac{a}{b}$ is the coefficient of supersaturation, which averages about 1.2. The results obtained are given in the following table:—

	Temp. of Massecuite.	Massecuite.			Strained Syrup.			Coefficient of Saccharose.	Crystals.	
		Rotation.	Water.	Quotient.	Rotation.	Water.	Quotient.		Per Cent. of Mass.	Per Cent. of Sugar.

Pentose, A New [from Wood-Sugar Molasses]: Lyxonic Acid and Lyxitol. G. Bertrand. Bull. Soc. Chim. 1896, 15, [3], 592–594.

This paper confirms the work of Fischer and Bromberg (Ber. 29, 581). In addition to lyxonic acid and lyxose, lyxitol was prepared by the further reduction of lyxose, and obtained in the form of a syrup. Lyxitol does not readily yield an acetal (with benzaldehyde, for example), differing in this respect from xylitol. As regards lyxonic acid, its strychnine, quinine, barium, and strontium salts are crystalline; the lead, zinc, and calcium salts, amorphous. In conclusion, a method is described for preparing lyxonic acid in quantity from the waste molasses of crystallised wood-sugar manufactories.—H. T. P.

Wood Gum, Composition of. S. W. Johnsen. J. Amer. Chem. Soc. 1896, 214–222.

1. From *Maize*.—Ground maize cobs were digested for 24 hours, with frequent agitation, in a mixture of 1 vol. of concentrated ammonia and 7 vols. of water, filtered, washed to remove ammonia, and digested for 48 hours with 7 per cent. caustic soda solution. The filtered extract was mixed with twice its volume of 93 per cent. alcohol. The precipitate was washed until the washings were neutral to test paper, then stirred up with dilute hydrochloric acid, again washed with dilute alcohol until neutral, and finally treated with absolute alcohol and ether, and dried over sulphuric acid. About 25 per cent. of white, easily powdered material was thus obtained, which answered to Thomson's description of wood gum.

It was not turned blue by iodine. Agitated with pure water at ordinary temperatures, a 0.14 per cent. solution was obtained, neutral in reaction. Boiled with water for six hours the solution contained 0.44 per cent. of dissolved substance, which very slightly reduced Fehling's solution. It was neutral, gave no precipitate with normal lead acetate, but a heavy flocculent precipitate with basic lead acetate. The average of three closely agreeing analyses gave: Carbon, 39.09; hydrogen, 6.73; ash, 0.61; moisture, 13.51; from which the composition of the dry and ash-free substance works out as according with the formula $C_5H_8O_4$.

By hydrolysis a syrup was obtained, which, after seeding with a little pure xylose, in a few days nearly solidified to a mass of crystals, which, when washed with alcohol and dried, melted at 153° C. The cobs of Indian corn therefore yield very pure xylan, $C_5H_8O_4$. Earlier analyses of wood gum, leading to the incorrect formula $C_6H_{10}O_5$, were probably made on imperfectly dried material.

2. From *Birch Wood*.—Preparations obtained from the wood of the American white or grey birch, *Betula alba*, differ in composition from the xylan of maize cob. Analysis points to the formula $C_4H_6O_3$. The gum, when hydrolysed, yields a syrup from which a very small proportion of

crystals can be separated, which do not appear to be increased in quantity by seeding with xylose crystals.

3. From *Vegetable Ivory*.—According to Reiss, this substance, the fruit of *Phytelphas*, yields about 7½ per cent. of yellowish-brown gum, soluble in water, levo-rotatory, and readily hydrolysed, yielding mannose. Reiss also obtained another carbohydrate as a white amorphous powder, which was found to swell and partially dissolve in water, reducing Fehling's solution; this, which he termed semini, also yielded mannose on hydrolysis. A quantity of refuse vegetable ivory received by the author with the information that "it had been used as a food for cattle, which ate it with great relish and fattened upon it," was subjected to "fodder analysis," with the following percentage results:—Water (at 100° C.), 18.78; ash, 1.08; crude fat (ether extract), 0.70; albuminoids (N × 6.25), 3.37; crude fibre, 7.50; nitrogen-free extract (by difference) 68.57.

Turnings of the materials were treated with ammonia, as described above for maize, then extracted with 10 per cent. potash solution, and the insoluble residue with a weaker solution. From each extract the gum was precipitated by alcohol in two fractions, and the four preparations thus obtained were purified, and two of them were analysed in an air-dry condition. The results yielded by the second fraction of gum from the first extraction closely correspond with the theoretical figures for pure mannan, $C_6H_{10}O_5$; the first fraction of gum from the second extraction contained about 0.5 per cent. less carbon, pointing to the presence of another carbohydrate.—L. PATENT.

Soluble Starch, An Impd. Process for Preparing. J. Kantowicz, Breslau, Germany. Eng. Pat. 5844, March 16, 1896.

This patent refers to the separation of soluble starch (rendered soluble in any desired manner) from its solution.

This is effected either by the addition of magnesium sulphate to the solution or by subjecting the latter to a temperature of -20° for about 10 hours.—A. K. M.

XVII.—BREWING, WINES, SPIRITS, Etc.

Sugars [Maltose, &c.], Ammonia Derivatives of Certain.
C. A. Lobry de Bruyn and F. H. van Leent. R. tr. ch. P.-R. 14, 134.

Maltose.—20 grms. of finely-powdered maltose are dissolved in 100 c.c. of methyl alcoholic ammonia, saturated at 17° – 18° C. (20 per cent. of NH_3) and set to crystallise (a less coloured product is obtained by replacing the methyl by ethyl alcohol). Water is eliminated in the reaction and *maltosamine* formed. The latter is comparatively stable; it does not lose ammonia in dry air, and may be recrystallised from hot methyl alcohol, from which it separates in needles, melting at 165° C. with decomposition. $[\alpha]_D^{20} = +110$.

Galactose yields two derivatives:—(1.) *Ammonio-galactosamine* ($\text{C}_6\text{H}_{10}\text{O}_5(\text{NH}_2)_2$), in groups of needles, m. pt. 113° – 114° C. This body is very unstable and gradually gives off its ammonia. $[\alpha]_D^{20} = 87^{\circ}3$, diminishing in two days to $62^{\circ}5$, at which value it remains sensibly constant. (2.) *Galactosamine*, ($\text{C}_6\text{H}_{11}\text{NO}_5$), obtained from the mother-liquor of the preceding compound, crystallises in long needles, m. pt. 141° C. It is stable and may be crystallised from boiling methyl alcohol. $[\alpha]_D^{20} = 64^{\circ}3$, very slowly diminishing to $58^{\circ}3$. The fixation of a second molecule of ammonia by this body is more or less prevented by the presence of water, and does not take place at all in an alcoholic solution containing 80 per cent. of water.

Xylose yields an osamine ($\text{C}_5\text{H}_{11}\text{NO}_4$) melting at 130° C. with decomposition. $[\alpha]_D^{20} = -18^{\circ}3$, which rises to $-0^{\circ}46$ in a fortnight.

Arabinose forms a very stable osamine, m. pt. 124° C., which is extremely soluble in alcohol. It may be precipitated by the addition of ether.

Rhamnose also furnishes an osamine, and at the same time fixes a molecule of alcohol. The resulting compound has the formula $(\text{C}_6\text{H}_{13}\text{NO}_5)\cdot\text{CH}_3\text{OH}$. It may be recrystallised from absolute alcohol. It melts at 116° C., and loses ammonia and alcohol even at comparatively low temperatures. $[\alpha]_D^{20} = +38$. The corresponding compound with ethyl alcohol fuses at 80° C. $[\alpha]_D^{20} = +28^{\circ}$.
—H. T. P.

Spirit, Direct Production of Good, from Asphodel and Squill with the use of Pure Cultivated Wine-Yeast.
Rivière and Bailhache. J. de la Distillerie Française, 13, (1), 609.

THE authors have previously shown that in order to obtain alcohol of good quality—that is, free from the greater part of the commonly occurring impurities—from beet juice, it is not sufficient to merely employ pure cultivated wine-yeast for the fermentation, but that an essential condition is the clarification of the juice with 1 per cent. of slaked lime, which effects the removal of objectionable nitrogenous matters. A similar method applied to asphodel (*Asphodelus ramosus*) and squill (*Scilla maritima*) has also given good results. These plants are very abundant in Algiers and Tanis, and the alcohol prepared from them in the ordinary way is of very low quality. In the method adopted by the authors, the plants were cut up, treated with hot water, and submitted to diffusion. The liquor was boiled and, when cold, treated with 2 per cent. of lime; the precipitate was filtered off after 48 hours, and the excess of lime precipitated with sulphuric acid. The exhausted residues were ground fine, boiled with 2 per cent. of sulphuric acid to convert the starch into fermentable sugar, filtered, supersaturated with lime so as to have 2 per cent. excess of the latter, and the treatment continued as above. The two extracts were then mixed, sterilised, and fermented with pure wine-yeast. When the fermentation was finished, the product was distilled, and a spirit obtained of agreeable taste. On analysis, it was found to contain considerable quantities of aldehyde, but no furfural, and only traces of the higher alcohols.—A. K. M.

Raw Grain: A Few Practical Remarks and Experiences.
A. J. Groom. J. Fed. Inst. Brewing, 1896, 2, 320–332.

THE author describes a short brewing of 55 quarters of grist, of which 25 per cent. was maize grits, with Billing's converter (this Journal, 1892, 628). 14 quarters of maize grits and 2 quarters of ground malt (for the purpose of adhesion) are placed in one division of a double-chambered hopper, the remaining 39 quarters of malt being ground into the second division. The converter contains 50 barrels of water; when the latter is raised to 120° – 124° F., the maize grits are run in, the machinery is set in motion, and the temperature increased to 150° F. The mixture is allowed to stand a short time, and the steam turned on full into the jacket in order to burst the starch cells. Some grits require a temperature of 195° F., others 200° F., before being gelatinised. The higher temperature is maintained for 20 minutes and subsequently lowered to the point required for striking the malt. The ground malt is then passed in, and the contents of the converter run into the mash tun. Care should be taken over this operation, as the fine grits may be forced into the slots of the false bottom of the mash tun. Brewings conducted in the above manner yield an extract of 97–98 lb. per quarter. The worts were generally cleaner than when malt alone was used, and there was less deposit on the coolers, fermenting vessels, and racking tanks. Satisfactory fermentations are said to have resulted; the ales are far more quickly acted on by finings, and are sounder and finer than malt beers.—J. L. B.

Slack Malt. N. Van Laer. J. Fed. Inst. of Brewing, 1896, 2, 363–373.

IN the author's opinion, malt containing more than 4 per cent. of moisture should not be used for brewing by the infusion system, since turbidity arising from slack malt is frequently met with in this method of working. In order to establish the cause of dimness in a sample of beer, it is filtered, and if the filtrate be clear, the turbidity is due to the presence of yeast; if the filtrate is cloudy a few drops of iodine should be added as a test for erythroextrin. Should the beer clarify on heating, the turbidity probably arises from hop resin or gluten; the resinous turbidity disappears when the beer is treated with finings, whilst that arising from gluten remains. If the filtered beer is still cloudy when warmed, the turbidity is to be ascribed to the presence of deleterious organised ferments.

IN Belgium, slack malt is worked by the decoction system known as "Dickmaische" or "thick mash," whilst in Germany the "Dickmaische" is used in combination with the "Lautermaische" (the milky and sedimentary wort in the tun after mashing). The principal feature of the Belgian method consists in the drawing off of the "Lautermaische" from the mash and treating it in the copper in various ways. The following is the method generally employed:—The grist is mixed in the mash tun with sufficient cold water to moisten the whole. Whilst the rakes are kept in motion, the goods are raised to a higher temperature by the addition of hot water. The milky liquid is drawn off and conveyed to the copper, where it is subjected to a saccharification temperature for a time sufficient to allow of the complete conversion of the starch, the temperature being subsequently raised to, and maintained at, 175° F. for some time. While this "Lautermaische" is in the copper, water is again run into the mash tun, at a temperature high enough to complete the saccharification of the remainder of the starch of the malt. One or two of the sedimentary worts are taken, according to the quantity of material used. The "Lautermaische" from the copper is filtered through the goods in the mash tun after the saccharified wort has been run off.

The combination of the "Dickmaische" with the "Lautermaische" referred to above, consists of drawing off a quantity of mash and raising it to the boiling point in the copper, after the mixing operations in the mash tun are complete, and then returning it to the mash tun to raise the temperature of the whole mash.

The author questions the use of mechanical devices for oxidising the wort whilst in the copper, when malts having

a tendency to glutinous turbidity are used. When a dried and warm malt is ground and used, it produces clear worts, whereas, if it be allowed to remain before being worked, the converse occurs.

Malt requiring re-drying should be placed on the kiln and kept at a temperature of 120° F. for 10 or 12 hours, the "lowres" being left open to allow of the escape of any moisture. At the end of this time the temperature should be gradually raised in 3 or 4 hours to 175° F., and this heat maintained for 4 hours. The temperature should subsequently be raised to 180° or 190° F., and kept at this for 5—12 hours, according to the quality of the malt treated. Re-drying never entirely removes all defects of slack malt, and care should be taken to prevent slackness by carefully storing the malt.—J. L. B.

Compound Ethers produced by Yeast from Green Malt and Wort. P. Lindner. *Wochenchr. für Brauerei*, 1896, 552—553.

When green malt is kept in a vessel with a plentiful supply of air, a strong odour of compound ethers is developed. If the grain be examined, a quantity of yeast cells will be found adhering thereto, which resemble *Saccharomyces Anomulus*. This yeast, when grown in wort, is known to produce a quantity of these ethers. A noteworthy observation is that the compound ether appears to act as an antiseptic.

The author has observed the production of compound ethers by many varieties of yeast. *Saccharomyces Apiculatus*, when grown in a well aerated solution of dextrose, gave a plentiful amount, but when grown in non-aerated wort, hardly a trace. This yeast has been recommended for estimating dextrose; the author is inclined to prefer *Saccharomyces eruginus*, which does not yield any compound ether.—A. L. S.

Beer, Light, Brilliant, and Sparkling; The Preparation of. O. Reinke. *Wochenschr. für Brauerei*, 1896, 548.

A light, brilliant, and sparkling beer is produced in many districts of Germany from various materials. In East Prussia the moderate local barley is used, but in most districts only the best barley malt, though usually with the addition of some raw grain or sugar; the grain being usually rice, and the sugar ordinary cane sugar.

All these beers are lager beers, and the leading principles underlying their preparation are: short time of boiling both the mash and the wort, and protracted fermentations at low temperatures. It is also found advantageous to harden the mashing water with gypsum.

In using maize there is great danger of producing a raw taste, unless the grain be carefully de-germed. Thin barley and a very slightly grown barley malt are also used. These raw grains are conveniently added in the mash copper.

The author does not recommend the employment of a low-fermentation yeast, and states that he knows breweries that have used Saaz yeast and not found it satisfactory.

—A. L. S.

Malt, The "Withering" of, in Pneumatic Maltings.

O. Reinke. *Wochenschr. für Brauerei*, 1896, 606—607.

The author considers the difficulty which is experienced in satisfactorily "withering" malt in pneumatic malting drums, is due to the expansion of carbonic acid by the large volumes of air which have to be passed through the drums, and he proposes to remedy this by drawing air for withering, from the fermenting cellars, where no difficulty would be experienced in obtaining any quantity of carbonic acid.

PATENTS.

Alimentary Liquid, An Improved. J. H. Hooker, Buckingham. Eng. Pat. 11,613, June 14, 1895.

A wort is prepared from malt, but in place of hot water, warm peptonised milk is used, or milk which is undergoing peptonisation. The wort is separated from the grains in the usual way, and boiled either with or without hops. Beer is then prepared from the boiled wort in the usual manner.—A. L. S.

Brewers' Mash, Method and Apparatus for Treating. V. Lapp, Leipzig-Lindenau, Germany. Eng. Pat. 14,482, July 30, 1895.

The apparatus consists of a rotary perforated cylinder, within which is a worm conveyor and a hollow perforated shaft. The cylinder is surrounded by a casing provided with exit pipe for the wort and fitted with steam or hot-water jacket. The mash is introduced through a pipe at one end of the apparatus, and as it travels along the perforated cylinder, the wort drains into the outer casing and is carried away through the exit pipe. Whilst the grains are being propelled along the cylinder, they are washed by the water passing through the spray holes of the hollow shaft.—A. K. M.

"Draft" or Spent Grains, Brewers' and Distillers', Utilisation of. R. D. Bailey, Gloucester, and L. P. Ford, London. Eng. Pat. 1788, Jan. 25, 1896.

The spent grains are mixed with water and heated to boiling. The product is cooled to below 60° and treated with diastase, malt extract, or "taka-moto" to convert the starch into maltose and dextrin. Sulphuric or other suitable acid (about 1 per cent.) is then added and the liquor boiled for 30 minutes; the maltose and dextrin are converted into dextrose, and a large proportion of the cellulose of the husk is converted into "fermentable furfuroid sugars." After neutralising, the liquor is settled and mixed with the ordinary wort, or may be used for other purposes.—A. K. M.

Margarin Manufacture in France. A. M. Villon. *Monit. prod. Chim.* 1896, 4.

The separation of the liquid olein from the solid fat of the tallow (premier jus) is effected by pressing the mass—previously formed into flat cakes, 20 × 18 × 2 cm.—in a

hydraulic press, some 200 of the cakes being treated at a time in layers of five, separated by linen cloths, warmed to 50° C. The olein begins to run from the heat of the cloths alone, and pressure is only applied when the flow diminishes.

The oleomargarin forms a yellow crystalline mass, the chief market for which is Rotterdam. The residual solid fat is used for candle-making. To work the oleo up into margarin, it is churned along with milk and cotton-seed oil, arachis or sesame oil, warmed to 45° C. (the melting point of the oleo), the proportions varying with the quality desired and the season:—

Oleomargarin.....	800 kilos, or 500 kilos,
Cotton-seed oil.....	100 " 50 "
Milk.....	500 litres 500 litres.

In winter, 30—40 per cent. of oil is used, whereas in summer it is sometimes entirely omitted. The function of the oil is to impart a buttery consistency to the product. Churning takes about two hours, and, when ended, the margarin is emptied into an inclined trough leading to a large tub. Cold water is sprayed on to the margarin during its descent, to produce granulation, and after floating in the water of the tub, the margarin is collected in sieves and left to drain in a perforated vessel for a couple of hours. Subsequently it is kneaded, to express the milk and render the mass homogeneous, in machines like ordinary butter-workers, and is finally made up in $\frac{1}{2}$ -kilo. pats.

Ice water is sometimes used in the cooling, but is not so suitable, hindering the development of the true margarin flavour produced in the slight fermentation allowed to occur before the mass is drained. The best results are obtained when the margarin encloses a small proportion of milk in setting, for which purpose the water should not be too cold.

"In order to impart the characteristic flavour of butter, the product is moistened, whilst draining, with a small quantity of ferment obtained from fermentation cultures from good butter."

It is stated that the agents of margarin-makers persuade agriculturists that an admixture of 5 or 10 per cent. of their article to butter is both innocuous and undetectable, with the result that as much as 50 per cent. of some butters consists of margarin.—C. S.

Meat, Butter, Cheese, and other Animal and Vegetable Substances; Impts. in the Method of and in Means and Appliances for Preserving. J. H. Fitter, London. Eng. Pat. 13,008, July 5, 1895.

The meat is stored in an air-tight room strong enough to sustain a vacuum. The room is encased by an external chamber filled with charcoal, asbestos, or other non-conducting substances.

The meat is first cooled and then placed in the previously cooled room, the door of which is then at once closed and rendered air-tight. A more or less complete vacuum is

then produced by an air-pump. The cooling is effected by the ammonia refrigerating process, the cold pipes being arranged in the inner chamber.

Although cooled, the meat is never actually frozen, and therefore keeps in better condition than by the old plan of freezing.—L. de K.

Cocoa Compounds, Impts. in the Manufacture of. O. Imray, London. From C. Rach, Chicago, U.S.A. Eng. Pat. 14,250, July 26, 1895.

A WEIGHED quantity of cane-sugar is dissolved in about one-tenth of its weight of water at a temperature of 280—290° F., and about an equal weight of cocoa is added, and the whole mixed at this temperature. After about 30 minutes the temperature of the mixture is reduced to 210° F., and four times its weight of milk added; this is thoroughly incorporated and the temperature raised to 240° F. The product is then evaporated, at first under ordinary pressure and finally in *vacuo*, until a dry mass is obtained. This forms the new product.—A. L. S.

Germ [Wheat] Extract, Impts. in the Manufacture of. A. Mackey Parker, London. Eng. Pat. 14,631, Aug. 1, 1895.

100 lb. of germ of wheat are mixed with 40 gallons of water at 100° F., and 300 grains of bicarbonate of potash are stirred in. After keeping the whole at this temperature for 1½ hours, the mixture is strained and the residue once more treated with 15 gallons of water at 100° F.

The mixed liquor, after adding 1 lb. of a preservative compound, such, e.g., as a borate, is placed in a settling vat and kept at a low temperature for 18—24 hours. The clear liquid is then drawn off and evaporated at 130° F. until it has acquired a suitable density, and, after filtering, 5 lb. of the best extract of malt are added. The extract is then ready to be filled in tins, and may be used for making bread biscuits, and certain aerated beverages.

—L. de K.

Alimentary Extract, The Manufacture of a New. E. Kressel, London. Eng. Pat. 15,885, Aug. 23, 1895.

BREWERS' yeast, preferably bottom yeast, is washed three times in pure water. The mixture is strained and then subjected to a temperature not exceeding 58° C., preferably in *vacuo*, to kill the yeast cells, but not to coagulate the albuminoids.

After being heated for three hours, the mass is filtered, and the filtrate evaporated to the consistency of a paste. If a powdered extract be desired, filtering is omitted, and after complete drying, the mass is ground.—L. de K.

Beverage from the By-Products of Dairies, The Preparation of a. A. Bernstein, Berlin, Germany. Eng. Pat. 23,590, Dec. 9, 1895.

TEN gallons of separated milk are poured into a vessel and heated to 35°, when rennet is added. After standing in a slightly warm place for two hours, the curd will be sufficiently contracted, and the whey may then be poured off.

This is then allowed to become sour to a point at which 25 c.c. require 15 c.c. of deci-normal soda for neutralisation. The same object may, however, be obtained by adding to the whey some citric or other suitable acid. The liquid is now heated in steam chambers for two hours to complete the coagulation of the caseine, and the albumin is then cooled to 5°—10° C., and filtered through thick cloth. The beverage thus produced contains the protein matter only in the state of albumose and lactoprotein.—L. de K.

Milk Products, Condensed, Impts. in the Manufacture of. W. F. Maclaren and A. Smith Fleming, both of Glasgow. Eng. Pat. 2081, Jan. 29, 1896.

The object of the invention is to prepare a wholesome condensed milk from separated milk. 40 galls. of the latter are mixed with 28 lb. of sugar and condensed to about 100 lb. To this is then added an emulsive compound consisting of 12 lb. refined beef oil (oleo oil), 8 lb. of lime water, 1 lb. of corn flour, and 12 lb. of sugar. The emulsifying is, preferably, carried out in a steam-jacketed pan provided with an agitator, the lime water being gradually added during the mixing operation.—L. de K.

Meat by the Help of Electricity, Preserving. A. B. Pinto, Rio de Janeiro, Brazil. Eng. Pat. 2176, Jan. 30, 1896.

The meat to be preserved is immersed in a 20 per cent. solution of common salt, and a continuous current of electricity is passed through the solution. In from 10 to 20 hours the salting is complete, and the meat is taken out and hung up to dry.

In working a bath of 3,000 litres of brine in which 1,000 kilos. of meat may be immersed, the current may be of 100 amperes with an E.M.F. of 8 volts. The electrodes must be of platinum, since if other metals such as zinc or iron were used, salts of these metals would be formed, and would be injurious.—A. L. S.

Milk, Cream, and other Liquids, Impts. in Apparatus for Sterilising by Means of Steam. A. T. Pfeiff, Copenhagen, Denmark. Eng. Pat. 7802, April 13, 1896.

The inventor points out the various drawbacks in sterilising milk by using hot water as the heating source.

In the new apparatus as the source of heat, steam is employed, and by means of an inverted U-shaped bell attached to a close-fitting lid, it is compelled to pass through the apparatus under pressure and divide itself into two streams, so that the liquid under treatment will receive heat on both sides. Suitable pipes are provided for carrying off the condensed steam.—L. de K.

Margarine or Butter Substitute, Impts. in the Method of and Apparatus for the Manufacture of. J. C. Uhlenbrock, Neuss, Prussia. Eng. Pat. 8194, April 18, 1896.

The usual ingredients are placed in a churn, and when sufficiently churned, the mixture is allowed to run into a trough, where it is not treated, as usual, with cold water, but with a jet of cooled skimmed milk or butter-milk. The stiffened product is then again churned, this time with the milk. The surplus milk flows through suitable pipes into a receiver, and may be used over again several times.

It is claimed that the margarin thus produced looks more like butter, has a nicer flavour, and keeps better.

—L. de K.

Antiseptic Preparations for the Preservation of Animal and other Foodstuffs, for use in the Manufacture of Butter, for the Prevention of or Removal of Taint from Animal Food Substances, including Beef, Mutton, Bacon, Fish, Game, Poultry, and for use in the Production of Beers, Light Wines, Aërated and Non-Alcoholic and other Drinks, and for other Purposes; Impts. in and connected with. J. Ascoug, Hand-worth, Stafford. Eng. Pat. 9345, May 2, 1896.

The preparations described are made by dissolving sodium carbonate and common salt in a small quantity of water, adding pure boric acid with sodium borate or calcium borate or "tineal sodium borate," stirring the warm mixture until it has become cold and has assumed a finely crystalline state, drying the product, and grinding it to a powder. Various proportions of the different ingredients are given.

Sewer Water, A Process for Treating, with the Double Object of Improving its Sanitary Condition and Separating and Utilising the Substances contained in it. E. Dussan, Paris. Eng. Pat. 12,388, June 26, 1895.

The process consists of the following successive operations, viz.:—"Spontaneous decantation"; treatment with hydrofluoric acid gas and fluoride of silicon; precipitation by means of lime; coagulation of the fatty matters by means of successive currents of compressed air, steam, and cold air.—L. A.

Sterilisation and Purification of Water [Ozone], Impts. in and Apparatus for. N. Van der Steen, Haarlem, Holland, and A. Schneller, Alfen, Holland. Eng. Pat. 16,308, Aug. 30, 1895.

Ozone is generated according to Eng. Pat. 23,297 of 1894 (this Journal, 1895, 493). The present invention refers in general to the means for bringing the ozone in intimate contact with the water to be sterilised and purified.

Ozone is admitted at the bottom of a chamber containing perforated plates at intervals, water flowing in from the top through the plates and out at the bottom. The water may be broken up, atomised into or within a stream of ozone.

—J. C. R.

Water, Softening and Purifying, Impts. in Apparatus for. O. Guttman, London. Eng. Pat. 11,739, May 29, 1896.

The hard water and the reagent solution are admitted, in regulated proportions, into the softening tank, in which they are heated or merely agitated together by any suitable means; the softened water is conveyed by an overflow pipe into a filter consisting of a long trough-shaped channel, divided by partitions into a number of communicating compartments filled with wood-wool, wherein it is clarified for use.—L. A.

(C.)—DISINFECTANTS.

Quinosol and Diaphtherine. Journ. Pharm. Chim. 1896, 3, [10], 495—496.

DIAPHATHERINE is a compound of one molecule of ortho-phenolsulphonic acid and two molecules of orthohydroxy-quinoline. It is a yellowish crystalline body, readily soluble in water and melting at 82°. Its aqueous solution gives a blue-green coloration with ferric chloride. According to Vulpius, quinosol is potassium oxyquinoline sulphate. The two bodies are easily distinguished by heating on platinum-foil; the former burns completely, the latter leaves a residue containing potassium. An aqueous solution of quinosol is coloured green by ferric chloride, and gives precipitates with HgCl₂ and lime water. The value of a sample may be estimated as follows:—1 gm. is placed in a graduated tube and water added to 10 c.c.; 1 gm. of sodium acetate in 15 c.c. of water is now added, and the mixture shaken out with 15 c.c. of ether; the volume of the ethereal layer is now increased to 20 c.c. and one half of it removed and evaporated; the residue should consist of oxyquinoline, melting at 70°, and should weigh not less than 0.25 gm., corresponding to about half the oxyquinoline in the sample taken.

According to a report from the laboratory of the Pharm. Soc. of London, quinosol is used as an antiseptic in aqueous solution containing from 0.1 to 2 per cent.; it is about 40 times more powerful than phenol.—T. E.

"Cresochine." Journ. Pharm. Chim. 1896, 3, [10], 497—498.

The substance which goes by the above name is composed of neutral quinoline tricrosyl sulphonate and of a compound of quinoline with trieresol. It contains 33 per cent. of quinoline and 17 per cent. of trieresol. The quantities of the different constituents may be determined by acidifying 100 c.c. of the substance with dilute sulphuric acid and extracting with ether. The trieresol left after the ether is evaporated should amount to at least 17 per cent. of the substance taken and should boil at 185°—210°. The aqueous solution is now made alkaline with caustic potash (it becomes blue) and extracted with ether. The quinoline is obtained on evaporating the ether; it should boil at 227°—237° and amount to 33 per cent. of the substance.

Cresochine is distinguished from solutions of cresols by the absence of alkalis; it is not soapy to the touch, and is not caustic; water (even hard water) gives a clear solution containing 5 per cent. of it. As a disinfectant it possesses the advantage of not evolving ammonia, like the alkaline preparations.—T. E.

XIX.—PAPER, PASTEBOARD, Etc.

Wood [for Paper], *The Treatment of, with Strong Acids*. Prakt. Handbuch der Papierfabr. 42, 1896, 1631—1632.

M. Z. ORIOLI, of Pontelarræ, France, has experimented upon a practical scale on the action of strong acids upon wood. It was found that both hydrochloric and nitric acids penetrated the wood and removed the encrusting matters, but the resulting products differed considerably with the different acids. Hydrochloric acid blackens the wood. Nitric acid does not blacken the wood, but it is somewhat costly. A solution of 20 per cent. of nitric acid and 80 per cent. of hydrochloric was found not to blacken the wood. With this solution, pine shavings were digested for 24 hours, producing a pulp that could be easily disintegrated with the fingers, the encrusting matter of the fibres having been entirely removed and converted into pectic acid. It was found that 100 parts of wood yielded 50 parts of long, strong white fibres, after treating with 40 per cent. of the above solution, washing, and then bleaching with 10 per cent. of bleaching powder. The sandstone vessels employed, had a capacity of 1,000 litres, and it was found that the acid penetrated through the cracks, causing considerable trouble. After being treated with acid, the wood was ground under granite stones, and washed. Messrs. Coupiér, Barre, Blondel, and Delaye, have tried at different times to obtain cellulose by boiling the wood with dilute nitric acid, and Baehet and Machard have tried to convert the encrusting matter of the fibres into glucose by boiling with dilute hydrochloric and sulphuric acids, but none of these methods have proved successful in practice. Orioli declares that wood cannot be profitably decomposed without acids, and believes in the treatment of Baehet and Machard, providing suitable plant is used. According to the Ger. Pat. 60,233 of Dr. I. Lifschütz and others, pine wood is treated with a cold mixture of dilute nitric and sulphuric acids in the proportion of 3 parts (by vol.) of the former to one of the latter. After a time the wood is removed and washed in water, and a weak solution of soda, yielding, it is said, 45 per cent. of cellulose. The acid is re-used until the nitric acid is exhausted, when it is practically a saturated solution of oxalic acid which separates out by crystallisation, and the sulphuric acid may be re-used with a fresh supply of nitric acid. Apparently this process has not yet been practically applied. —S. P. E.

The Preservation of Wood Pulp. Translated especially for Hardwood from the *Moniteur Industriel*.

THE Association of German manufacturers of wood pulp has offered a prize of 3,000 marks (150*l.*) for the discovery of an efficacious means of preserving wood pulp in a damp state. It has been known perfectly well for a long time that manufacturers could preserve the pulp for only a short period, although in the moist condition it permits paper-makers to use it without difficulty and without previous preparation. Of course, if the pulp is preserved in a desiccated condition, in the form of coarse pasteboard, which does not add materially to its original cost, it can be kept for some time without any material or deleterious change. But before it can be used in the manufacture of paper it must be macerated or ground up, which adds greatly to the expense, and, besides, many paper mills have not enough of the necessary macerating machinery. Many European paper-makers experienced this trouble in a marked degree during the winter of 1893-94, from the general decrease of the water supply, owing to a widely-spread drought, their mills being run by water-power, and they were obliged to use an old stock of pulp, which could only be procured in a dry state. At the present time two processes of preservation are under trial, which are recommended by Mr. Chr. Braun, of Roehsburg, Saxony. One method consists of running the wet pulp from the machine on to an endless sheet of thin linen, 1.5 to 3 mm. thick, and which is not submitted to any pressure. This leaf or sheet of pulp is extremely spongy, and is either dried in the sun or artificially. The pulp thus prepared, contrary to the ordinary pasteboard pulp, which is pressed to extract the moisture, is thinned very easily in the desiccators, and

keeps in good condition for some years. Nevertheless this process implies the expense and delay of drying the pulp, and this fact has induced Mr. Braun to try the following method at a much less expense:—He dug long trenches in the earth, which he lined and covered with boards to prevent the paste from getting dirty. Down these trenches he ran the wet pulp, and the water separated by gravity, by absorption, and by evaporation, leaving the pulp in a condition still moist enough for use without re-desiccation. It is claimed by Mr. Braun that pulp prepared by this process gives very satisfactory results nearly five years after it is manufactured. This process, notwithstanding, still leaves a want unsupplied, under certain conditions, and this is why the German society has offered a reward of 3,000 marks for an entirely satisfactory process of preservation.

Paper made from Wood Pulp, Durability of. Prakt. Handbuch der Papierfabr. 42, 1896, 1633—1634.

PULP prepared by grinding wood, contains ligneous and other encrusting matters, and the composition is similar to that of the wood itself. Paper made from this pulp turns brown, and becomes brittle and rotten, when exposed to the action of light and air for any length of time. Pure wood-cellulose fibres are not affected by light or air, hence it is assumed that the above results are owing to the presence of the encrusting matters. Paper made from brown pulp is less sensitive to light, since the encrusting matter is partly removed by steaming and lixiviating. Cellulose made from wood by boiling with soda stands the action of light and air without turning brown, although it undergoes considerable change of another kind. Some years ago some blotting paper was made by an American firm from soda wood cellulose, and it was admitted by the makers that after a time the paper lost its absorbing qualities and in a few years became rotten, the fibres becoming again encrusted. A test of blotting paper several years old, confirmed this view. From this and other observations, it is suggested that certain cellulose pulps are liable to return by degrees into the state of the original ligneous fibre. Whether papers made of sulphite fibre will remain unaffected in the course of years is as yet uncertain, although many paper-makers assert that sulphite fibre is as suitable for documents as rag fibre.—S. P. E.

Sulphite Liquors from Wood Pulp, Utilisation of [Fuel]. Papier Zeit. 1896, 21, 1183.

See under H., page 579.

Sulphite Cellulose, Half-Stuff. Prakt. Handbuch der Papierfabr. 42, 1896, 1631.

THE treatment of wood by the sulphite process is preferable to the soda treatment, inasmuch as in the former process 20 to 30 per cent. more fibre is obtained from the wood. The quality of the cellulose fibre obtained by the sulphite treatment may be modified to suit the purpose for which it is to be applied. Boiling for a longer or shorter time at a higher or lower temperature enables one to produce a strong or weak fibre, a hard or soft pulp, having properties similar to hemp, cotton, &c. The chemicals required for its manufacture (lime and sulphur) are so cheap that it is unnecessary to recover them, which operation is essential in the soda and sulphate processes. In addition to the ordinary white ground wood pulp, the brown steamed wood pulp and the soda and sulphite cellulose fibres, some manufacturers are now producing a pulp of an intermediate quality between ground wood and cellulose fibres. A number of mills, especially in Sweden, are now making paper from this semi-cellulose, the method of production having so far been kept a secret.—S. P. E.

Sizing of Paper, The Influence of Sunlight on the. W. Herzberg. Die Chem. Ind. 1896, 19, [7], 137—141.

THE object of sizing paper is to limit the absorption and prevent the spread of ink. To ascertain what the observed destruction of the size in certain cases was due to, five various resin-sized papers were exposed to the influence of sunlight between double windows. The papers were previously tested for the amount of size, and all found normal.

The tests began on June 13th, 1888, when characters written upon them were clear. The papers were inscribed again on August 16th, and again on October 26th, when the sizing was again tested and proved to have altered considerably. The windows faced the east, and the sun could only shine on the exposed samples in the mornings. It is thus probable that the alteration would have been greater under more continued exposure. The appearance of the papers in October, after four months of the exposure referred to, were as follows :—

1. A paper made from linen and cotton without clay. The last characters showed an inclination to run, but the paper proved to be the same in size.

2. A foolscap paper, made from linen, cotton, and sulphite, without clay. The thin characters ran and the thick ones went right through.

3. Invoice paper (an ordinary yellow writing paper), made from wood pulp and sulphite, with 13.5 per cent. of ash. The characters were clear, and the paper proved to be well sized according to Leonhardt's method.

4. A white foolscap paper, made from straw, sulphite, linen, and cotton, with 13.8 per cent. of ash. All the characters ran, and the thicker ones went through.

5. A document paper, made from unbleached linen rags, without clay. The same appearance as No. 2.

The external appearance of the papers was as follows :—No. 5 was unaltered, Nos. 1, 2, and 4 showed signs of becoming slightly yellow, and No. 3 was very much discoloured.

Consequently four of the samples were totally unfit for writing purposes after four months' exposure, whilst the fifth, made from inferior materials, showed the greatest durability. The greatest alteration was in No. 4, made from sulphite and straw.

Other tests were made during 1890. Besides resin-sized papers, animal-sized papers were exposed. One sample was specially sized, by soaking an unsized sample of copper-plate printing paper in a solution of resin in ether. This paper therefore contained only free resin, and was fully sized. The composition of the papers was unequal, some being made from pure rags, some from rags, wood pulp, and sulphite, and some from pure sulphite.

The effect of two years' exposure to light was the same on all papers, the size being destroyed; but the degrees of destruction were unequal. The greatest effect was shown with the paper specially sized with ethereal solution of resin, in which, after exposure for one month (January), the size was weakened so much that the characters written on the paper ran, and the ink went through. The animal-sized papers lost their size completely, the ink spreading and going through.

To prove that only the light caused the loss in sizing, certain of the samples were covered so that, whilst the light could not reach them, the air had free access. After exposure, the covered parts were unaltered. With the animal-sized papers, however, the covered spots were slightly altered, this proving the existence of some other injurious factor.

Warmth was proved to be injurious.

Besides the above experiments, the following are described :—Wolesky and Haase exposed 17 samples of paper, of different compositions and sizing, to the influence of light from October 13th to November 9th, 1895, and made the following observations :—

1. Animal-sized paper does not show any perceptible deterioration in the sizing.

2. Resin-sized, highly glazed paper shows a considerable deterioration after a few days. After three to four weeks such paper loses the sizing so much as become as absorbent as blotting paper.

3. Resin-sized, unglazed papers resist rather more than glazed papers, but the difference is only to the extent of a few days.

Liesegang exposed samples of paper to sunlight, and found that it destroyed the size in resin-sized papers, but if the paper contained wood pulp the alteration was not noticeable.

By the examinations of Wolesky and Haase, and of Liesegang, &c., paper containing wood pulp does not show

any alteration, but in the experiments lasting a longer period (two years), the same papers had lost their size. Also animal-sized papers were not affected in Wolesky and Haase's experiments, but lost their size after two years' exposure. These show that the difference is due to the difference of time during which they were exposed.

A resin-sized paper, made from linen rags, was half covered, and the other half exposed to light. The uncovered part absorbed water in greater quantity and quicker than the covered part. The paper was soaked with a pyrogallol solution, when the part which had been exposed to light turned brown, the other part being only slightly coloured. Paper containing wood pulp gave the same reaction. Liesegang thinks that wood pulp plays a part similar to the Na_2SO_4 used in photography in the pyrogallol developer, the light acting first on the pulp and later on the size.

The surface of a piece of resin, or a glass plate coated with resin, when exposed for a long time to sunlight, becomes dull, and shows numerous cracks and flaws. In resin-sized paper similar action would lead to the spread of ink between such cracks and flaws. Another observation demonstrated that the action of light on resin-sized paper renders resin insoluble. A drop of ether on the samples at first gave on evaporation a distinct border of resin, particularly on the specially resin-sized paper, but after two years' exposure no trace of resin was dissolved by ether.

In animal-sized paper, the alteration of the covered part was undoubtedly due to cracks in the coat of size by changes of temperature, moist and dry air, &c. The following experiment is quoted :—A piece of animal-sized paper crumpled till full of wrinkles has the coat of size broken up and is no longer well sized, the ink penetrating the numerous cracks and spreading, giving thus the same result as in paper exposed to light. (See also this Journal, 1895, 1059.)—S. P. E.

Adansonia Fibre [Paper]. Prakt. Handbuch der Papierfabr. 42, 1896, 1642—1643.

This fibre is the bast of the baobab (*Adansonia digitata* L.), found in the tropics, principally in West Africa, in Senegal, and Abyssinia. The imported adansonia fibre chiefly comes from the Portuguese province of Angola, south of the Congo. The baobab grows in marshy as well as dry soil, on the banks of rivers and on table-lands. The trunks are seldom over 6 metres high, but very bulky, being sometimes 8 metres in diameter. After removing the external bark, which is useless, the bast is cut away, commencing about half a metre from the summit of the stem, and continuing down to within a metre of the bottom. The thickness of the strips is about 2 cm., and the length 1 to 1½ metres. After drying the strips in the sun for about a fortnight, they are ready for sale. The trees do not suffer from this treatment, a new layer of bast of about 1 cm. thick forming again in two years, although four years are generally allowed before cutting them again. Owing to the toughness of the bark, the adansonia fibre is difficult to obtain, and it is only profitable to collect in countries connected with the coast by rivers, overland carrying being too costly. The factories collect the fibre in small quantities, until they have sufficient for shipment, when it is baled in packages of 200 kilos, and sent to Europe. The price at Rotterdam is 17. per 100 kilos. At the paper-mills the strips are cut like ropes, with an ordinary rag-cutter, and are then boiled with 3½ per cent. solution of caustic soda for about 10 hours, under a pressure of 3—3½ atmospheres. The pulp produced is soft, and readily disintegrated. After boiling the raw fibre with a 15 per cent. caustic lime solution for six hours, the pulp was soft enough to beat in the hollander, but contained a large number of small dark specks. To remove these, the pulp was boiled a second time with a 20 per cent. solution of caustic lime, the effect being the production of a softer pulp and darker specks. It is essential that the fibre be covered with the solution before admitting steam, the latter darkening the fibre if dry. Fermentation and decomposition quickly set in when the pulp is stored moist, thereby reducing the strength of the fibre. The pulp requires considerable washing, otherwise the glutinous matter quickly clogs the

machine wire, drums, &c. 40 to 50 kilos. of paper are obtained from 100 kilos. of the raw fibre. Adansonia fibre is principally used for the manufacture of high-class wrapping papers, emery-paper, &c., and the strength of the fibre in a sheet of paper is only surpassed by that of the Japan mulberry tree. Owing to the small dark specks invariably present in the pulp, this material cannot be used for writing or drawing papers.—S. P. E.

Wood Cellulose in Paper. Testing of. Leipziger Papier-testing Inst. Papier Zeit. 1896, [44], 1417.

See under XXIII., page 619.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

Ether. M. Klar. Die Chem. Ind. 1896, 19, [7], 141—142.

ATTENTION having been turned to the use of ether as an anæsthetic, it has been proved that it causes less fatalities, and still less secondary effects, than chloroform. Pure ethyl ether is therefore more suitable in most cases than chloroform. Endeavours have been made to obtain a chemically pure ether—a so-called ether *pro narcosi*—for the trade; and recently a preparation obtained by distillation over metallic sodium has been introduced. This preparation even surpasses the claims of the German authorities for a pure ether. On testing it, chemists were surprised to find that such ether gives an aldehyde reaction with fuchsine sulphite (Schiff's reaction, this Journal, 1896, 560), and that it turns moist litmus paper blue, and does not redden phenolphthalein.

The ether, when freshly distilled over sodium, has a specific gravity of 0.717 to 0.718, and answers to the tests of Schering. But if the ether is not, immediately after its rectification, drawn off into bottles and carefully stored, it increases in specific gravity in a short time (0.720). The German authority, D. A. B. (Deutsches Arznei-Buch), requires ether of 0.720 sp. gr., thus allowing minimum traces of water and alcohol. It is extremely difficult to manufacture ether having exactly 0.720 sp. gr. The purest ether is of 0.717 to 0.718 sp. gr., but this absorbs water from the atmosphere, and rises to 0.720 to 0.721 sp. gr., when it assumes a certain steadiness. This property of absorbing small quantities of water is the cause of a good many differences between buyer and seller, as ether which left the manufactory with sp. gr. of 0.720, has, after repeatedly opening the bottles, drawing off, &c., absorbed water and risen to 0.721 sp. gr.

For specific gravity determination, the ether should be brought to 15° C. in a stoppered bottle with a narrow neck, fitted with a thermometer, and the specific gravity determined on the Mohr balance.—S. P. E.

Chloroform, New Method of Preparing. Chem. Rev. [39], 1896, 88—89.

To 75 kilos. of carbon tetrachloride are added, in the cold, 60 kilos. of hydrochloric acid (22° B.), and 50 kilos. of zinc, the whole being then heated in an autoclave. Hydrogen is liberated and reduces one atom of chlorine with the formation of hydrochloric acid which attacks the zinc anew, and the cycle continues until the process is complete, a condition indicated by the cessation of the formation of the hydrochloric acid. The upper layer of the substance is removed and the product refined.—C. S.

Acetone and Acetone-Chloroform, The Manufacture of, from Acetic Acid. E. R. Squibb. J. Amer. Chem. Soc. 1896, 231—247.

THE author has described a process for making acetone from acetic acid by passing the vapour of the acid through a rotating horizontal tube filled with barium carbonate or pumice stone (this Journal, 1895, 506). Since then, a large rotary still, 12 ft. long × 2 ft. diameter, has been set up and has decomposed in 126 hours about 1,700 pounds of absolute acetic acid, giving about 90 per cent. of the theoretical yield against 80 per cent. in the small experimental apparatus. This process and apparatus have

been objected to by the owners of certain patents by G. Rumpf for making acetone from acetates. The acetone made by this process was converted into chloroform, which was also objected to as an infringement of one of Rumpf's patents. The present paper contains the results of an inquiry into the history of acetone and acetone-chloroform, and a critical examination of the claims put forward by Rumpf.

With regard to acetone, it is shown that the manufacture of it from acetates was well known in 1818, and that prior to 1842 Liebig and Pelouze had described the preparation of acetone by leading the vapour of strong acetic acid through a heated tube of glass, porcelain, or iron, filled with pieces of charcoal to increase the surface. Rumpf in his patent application (1886) claims that he has improved the yield of acetone from acetates; but he makes no mention of acetic acid, and his apparatus and process are said not to be applicable to the use of the acid. Nevertheless, infringement is claimed on the ground that acetic acid is made from acetates and acetates from acetic acid. It is also alleged that the author's process is not a destructive distillation of acetic acid, but that the carbonate of barium he uses is first converted into the acetate which is then decomposed; in support of this, it is contended that if the barium carbonate be replaced by an inert substance like pumice very little acetone is formed. A number of comparative experiments was therefore made in the large rotary still, with the result, that whilst acetic acid alone heated in the empty still gave no acetone below 400° C., the presence of pumice caused the production to commence at 300° C., and a much larger yield was obtained at temperatures below 500° with pumice than without. The author also points out that barium acetate decomposes at 400°—405° C., whilst the most suitable temperature for the decomposition of acetic acid is fully 100° higher.

The preparation of chloroform from acetone is no new discovery, having been referred to by Liebig in 1832. Böttger, in 1848, showed how to prepare chloroform from acetates and from acetone, and stated that chloroform made directly from acetone was to be had in the market, 1 oz. of acetone yielding 1½ oz. of chloroform. Why this method of manufacture has not been generally followed up is doubtless owing, it is alleged, to the erroneous statements of Siemerling (1848) and Wackenroder, adopted by such authorities as Gmelin and Watts, who somehow failed to obtain anything like the proportion mentioned by Böttger. Thus Watts (1883), quoting Gmelin, states that the manufacture of chloroform from acetone cannot be usefully carried out, because acetone yields only about one-third of its weight of chloroform when treated with chloride of lime. But it is easily shown that Siemerling used only about half the theoretical proportion of chloride of lime, and he made no attempt to recover and treat again the acetone left unconverted. Rumpf bases his patent (1886) upon Watts' erroneous quotation, and claims the discovery that by using about double Siemerling's proportion of chloride of lime, 180 parts of chloroform for every 100 parts of acetone could be obtained. As proportions and results approximating Rumpf's had been published previous to Siemerling's paper, there is no discovery here. Yet to avoid litigation, and partly because he has found that by taking an excess of acetone the hypochlorite is more economically and promptly utilized, and the resulting chloroform cleaner, whilst the unconverted acetone is easily recovered and treated again, the author proposes to use Siemerling's proportions, and to carry out the whole operation in an apparatus described by himself in 1857, and used for many years for making chloroform from alcohol. It is proposed to use charges of 280 lb. of absolute acetone to 1,400 lb. of 35 per cent. bleaching powder, to pass the resulting chloroform through scrubbers, then distil it through water, and afterwards from a little bleaching powder, then pass it through sulphuric acid scrubbers, and finally rectify it in three fractions, accepting the large middle fraction and working the first and last over again. Part of the large excess of acetone taken is recovered by continuing the distillation after all the chloroform is over, and the remainder is almost wholly recovered from the wash water; this, carefully assayed, is mixed with fresh acetone for the next charge.—L. A.

Lemon Juice, Citric Acid in. H. H. Robins. Chemist and Druggist, 1896, **48**, 742—743.

ACCORDING to the British Pharmacopœia, 1867, lemon-juice was official if it contained $32\frac{1}{2}$ grains of citric acid per fluid ounce. In the present edition, however, the standard is raised to 36—46 grains. The author's experience, extending over many years, as well as that of other workers whom he quotes, indicates that the present standard is too high; also that the proportion of citric acid in natural lemon-juice frequently falls below even the lower limit (36 grains). The bulk of the lemon-juice sold in this country is squeezed from fruit arriving in December and January (lemons of these shipments are considered to be richest in citric acid), and was found to average (during nine seasons) 33.4 grains of acid per ounce. Whilst Palermo and Messina fruit (1895) yielded 33.3 and 23.4 grains respectively, the general average being about 35 grains per ounce. It is suggested, therefore, that in the next edition of the British Pharmacopœia the standard be altered to 33 grains and upwards of citric acid per ounce.

—H. T. P.

Phenylcoumalin. J. A. Leben. Ber. **29**, 1673—1680.

THIS substance, which occurs together with cotoin and *p*-cotoin in coto bark, has been investigated in several directions by the author. Separated by Ciamician and Silber's method the compound melts at 68° C. (Ber. **28**, 1557; this Journal, 1895, 881), and on heating for some time (24 hours to 110° C.) with hydrochloric acid it is polymerised to $(C_{11}H_8O_2)_n$, which melts at 219° C. (Ber. **27**, 845; this Journal, 1894, 756). When reduced with sodium amalgam, or better with hydriodic acid in acetic acid solution, phenylcoumalin yields β -phenylvaleric acid, crystallising in white rhombic plates, melting at 59° C. Phenylcoumalin readily forms addition products with phenolic compounds, of which the oldest known is phenylcoumalin-cotoin (dicotoin). New compounds of this class are those with picric and salicylic acid. By boiling phenylcoumalin with aniline, small yellowish nodules are obtained, which melt at 142° C., and have the composition $C_{11}H_8O_2 \cdot 2C_6H_5 \cdot NH_2$.—T. A. L.

Scopolamine and Atroscine. O. Hesse, Ber. **29**, 1776—1785.

THE alkaloid extracted from the root of *Scopolia atropoides* together with hyoscyamine has been termed scopolamine, although it was subsequently shown to be identical with hyoscyne. The two names are, however, used to denote the origin of the alkaloid, the former being employed when it is obtained from the root of scopolia, whilst it is termed hyoscyne when prepared from hyoscyamus. Scopolamine is said to have more active physiological properties than hyoscyne, and investigation has shown that commercial scopolamine hydrobromide contains, together with hyoscyne hydrobromide, the hydrobromide of a new alkaloid which the author terms atroscine, and identified by its lower rotatory coefficient. The alkaloid, which has the composition $C_{17}H_{21}NO_4$, gives a crystalline hydrate containing $2H_2O$, melting at 37° C. By the action of potash the alkaloid is decomposed into oscine and atropic acid. The substance is a strong base and gives characteristic salts, the solutions of which do not rotate polarised light. Attempts to convert hyoscyne into atroscine were not successful. With regard to the determination of atroscine in hyoscyne or scopolamine hydrobromide, which depends upon the rotation of the plane of polarisation, the following details are given. Hyoscyne hydrobromide, crystallising with $3H_2O$, gives, in an aqueous solution at $t = 15^\circ$ and $p = 4$, $[\alpha]_D = -22.5$. In 25 c.c. of solution, this concentration is obtained by dissolving 1 grm. of the crystallised, or 0.877 grm. of the anhydrous salt. Under these conditions, if the rotation be a and the scopolamine only contain hyoscyne and atroscine, then the percentage of true hyoscyne hydrobromide in hyoscyne or scopolamine hydrobromide is $\frac{100a}{22.5}$ or $\frac{100a}{25.7}$ if the anhydrous salt be used. Since a determination of the water of crystallisation must always precede that of a , it is preferable to employ the anhydrous salt. Based on this

method the author gives some numbers which he has obtained:—

	I.	II.	III.	IV.	V.
a	-22.1	-12.7	-12.1	-10.0	-11.3
Hyoscyne hydrobromide	85.9	43.4	47.1	38.5	43.9
Atroscine hydrobromide	15.0	50.6	52.9	61.5	56.1

The values can be easily converted into those for the crystallised salt, since both atroscine and hyoscyne hydrobromide contain $3H_2O$. With regard to its physiological properties, atroscine appears to act similarly to atropine and scopolamine so far as its action on the pupil is concerned, but is from two to four times more powerful in affecting the accommodation. In cases of iritis too, the new alkaloid acts more powerfully. For the oculist, therefore, it is of importance to have a hyoscyne hydrobromide with a low rotation, and the author, in conclusion, points out that the term scopolamine is superfluous, and should be no longer used.

—T. A. L.

New Method of Treating the Vanilla Pod. Board of Trade J., Aug. 1896, 207.

THE *Independent Créele* of Réunion contains a paper by Mr. Dolabaratz, upon a new process of treating the vanilla pod.

According to M. Dolabaratz the operation consists of drying the vanilla in an hermetically closed vessel by means of chloride of calcium, in the proportion of about 1 kilo. for every kilo. of dried vanilla obtained. The chloride of calcium is not lost, as it can be easily regenerated by heating it in an iron or copper receptacle; one lot of chloride of calcium is thus sufficient for several processes if kept, after regeneration, in an hermetically closed vessel.

According to information received, 2.981 kilos. of raw vanilla will produce about a kilo. of prepared vanilla.

It can be easily understood that vanilla dried in an airtight vessel must lose much less vanillin than when dried by the ordinary process, by which it is exposed in the open air for several weeks.

Licarcol, Licarhodol, and Limonol, Action of Gaseous Hydrochloric Acid on, Relation between the three Alcohols. P. Barbier and L. Bonveault. Bull. Soc. Chim. 1896, **15**, [3], 594—597. (See this Journal, 1893, 783.)

THE above isomeric alcohols all absorb hydrochloric acid readily, with evolution of heat, water being eliminated, and when saturated with the gas and fractionated, yield as chief product one and the same compound, an oily liquid, distilling under 10 mm. pressure at 120°—125° C. The oil has the composition corresponding to the formula $C_{10}H_{15}Cl_2$ (sp. gr. 1.0569), and appears to consist of a mixture of two isomeric bodies. When boiled with an acetic solution of dry potassium acetate, the chlorine is abstracted, and the product on fractionation yields (1) A mixture of hydrocarbons ($C_{10}H_{16}$) boiling at 170°—180° C.; (2) Limonol acetate from which, by saponification, a very pure inactive limonol may be regenerated. The limonol used in this investigation was derived from the essence of *Andropogon schoenanthus*.

The authors maintain, however, that licarcol and licarhodol are distinct chemical species, differing in constitution not only from each other, but also from limonol.—H. T. P.

Methylamines, a new Method of Separating them.

M. Delépine. Comptes rend. 1896, **122**, 1064—1066.

TWO methods of Hofmann and of Heintz are not very satisfactory. The new method is based on the action of formaldehyde on the methylamines. Henry has shown that monomethylamine reacts with formaldehyde to give a body $(CH_2 \cdot N(CH_3))_3$ boiling at 166°; whilst dimethylamine gives two compounds, $OH \cdot CH_2 \cdot N(CH_3)_2$, and $CH_2 \cdot N(CH_3)_2$, boiling between 80° and 85°. Trimethylamine, which boils at 9°, does not react. In putting the process into practice, the concentrated solution of the hydrochlorides of the amines is treated with caustic soda and the gas evolved

is collected in a 40 per cent. solution of commercial formaldehyde. By treating the liquid so obtained with an equal weight of caustic potash the greater part of the trimethylamine is evolved, and the liquid itself separates into two layers. The upper layer is dried over solid caustic potash, and submitted to fractional distillation; the remainder of the trimethylamine having passed over, fractions are collected boiling at 67–68° and at 166°. The former fraction contains a quantity of methyl alcohol derived from the impure formaldehyde. The amines may be regenerated by boiling the condensation products with alcoholic hydrochloric acid.

The process thus yields trimethylamine in solution, and the pure hydrochlorides of di- and mono-methylamine; it is simple, and does not, like the method with ethyl oxalate, necessitate the desiccation of the amines.—T. E.

PATENTS.

Mandelic Acid and Nitrile of Mandelic Acid, Impts. in the Manufacture of. Chemische Fabrik, vormals Hofmann und Schoetensack, Gernsheim, Germany. Eng. Pat. 11,886, Aug. 6, 1895.

The production of the nitrile by action of an aqueous solution of potassium cyanide upon an alkaline bisulphite compound of benzaldehyde is claimed, also the conversion of the nitrile into mandelic acid by agitation with concentrated hydrochloric acid, and finally heating.—A. C. W.

Camphor, Process for Preparation in the condition of Powder. W. Schmidt, Philadelphia, U.S.A. Eng. Pat. 17,351, Sept. 17, 1895.

PULVERULENT camphor is claimed as a new article of manufacture and the process for obtaining it by dissolving in a solvent of low boiling point (60–100° C.), and subsequent removal of excess of solvent by distillation, after a previous filtration, if necessary.—A. C. W.

Alkylglycollic Acid Derivatives of p-Amidophenol Ethers, Manufacture of. Basle Chemical Works (Bindschedler), Basle, Switzerland. Eng. Pat. 8770, April 25, 1896.

This patent claims substances of the above class and their processes of manufacture by the reaction (1) of haloacet-p-amidophenol ethers with sodium alcoholates—

(2) of the alkylglycollic acids with p-amidophenol ethers.

The bodies formed by these reactions are valuable as antipyretics and antineuralgics.—A. C. W.

Artificial Musk, Impts. in Process for Making. Gretsche and Mayer, New York, U.S.A. Eng. Pat. 9521, May 5, 1896.

THE following process and portions of it are claimed. Cold sulphuric acid is saturated with the soluble constituents of naphtha or kerosene, the solution so obtained is nitrated, gradually heated, neutralised, and the odoriferous substance precipitated by the addition of a metallic soap. In the last operation an alkaline resin soap is used and then a

suitable salt, e.g., aluminium sulphate, added, the precipitate is washed with water and then with alcohol, the alcoholic solution containing the purified musk.—A. C. W.

New Perfume or Odoriferous Principle [*Homovanillin*] and *Process for the Manufacture of.* Chemische Fabrik von Heyden, Radebeul, Germany. Eng. Pat. 11,166, May 22, 1896.

A PERFUME having the composition of a homovanillin, together with its manufacture by the action of chloroform on homoguaiacol in alkaline solution (Tiemann and Reimer's reaction) is claimed. The homovanillin thus obtained has probably the following formula—

has an adhering smell similar to that of vanillin, and crystallises from alcohol in colourless scales, melting at 165° C.—A. C. W.

XXI.—PHOTOGRAPHY.

Photography, Recent Impts. in. J. M. Eder and E. Valenta. Dingl. Polyt. J., 300, 42–43.

ACCORDING to Belitzky a very good emulsion for collodion paper is obtained by the preparation of the following solutions:—

First Solution.—Strontium chloride, 30 parts; lithium chloride, 10; distilled water, 62; and alcohol (absolute), 138 parts.

Second Solution.—Silver nitrate, 12 grms.; water, 16; and alcohol, 30 grms.

Third Solution.—Citric acid, 20 grms.; alcohol, 80 grms.

Fourth Solution.—Glycerin and alcohol, equal parts.

Four hundred grms. of crude collodion of 3 per cent. are mixed with 10 to 20 grms. of the first solution; then 20 grms. of glycerin-alcohol, prepared as described, are added; after that a small portion of the second solution is added, and the mixture well shaken; finally 20 grms. of the third solution, together with 50 c.c. of ether, are added. Baryta paper is used for the emulsion thus obtained.

Emulsion of Silver Chloride Collodion for Diapositives.—Zinc chloride, 6 grms.; citric acid, 2 grms. tartaric acid, 1 grm.; and alcohol, 240 c.c.

To the solution thus obtained one drop of ammonia, 12 grms. of collodion-wool, and 450 c.c. of ether are added. When this "chloride-collodion" is completely dissolved, the following "silver collodion" is added:—Silver nitrate, 30 grms.; water, 20 c.c.; and alcohol, 450 c.c.

To this solution there are added 12 grms. of collodion-wool and 240 c.c. of ether.

The emulsion is allowed to stand for six to eight hours, and then the plates are thickly coated with it. Before copying, the plates are for a short time exposed to ammonia vapours.

The number of developers for dry plates is daily increasing. Lumière and Seyewetz recommend phenyl-hydroxylamine as follows:—Phenylhydroxylamine, 1 grm.; sodium sulphite (anhydrous), 3 grms.; and water, 100 cc.; potassium bromide (1:10), 6 cc.

Andresen recommends amido- and hydroxy-compounds of p-phenylenediamine and p-toluylenediamine as developers.—H. S.

Photography, Recent Progress in. J. M. Eder and E. Valenta. Die Chem. Ind. 19, [13], 1896, 259.

DURING the past few years Hauff's "metol" (methyl-paramidometaacresol) has become very largely used as a developer. It may be improved for portraiture especially by the addition of sodium thiosulphate. A suitable formula is (A) metol, 15 grms.; sodium sulphite, 150; water, 1,000 c.c. (B) "hypo," 1 grm.; sodium carbonate (cryst.), 330; water, 1,000 c.c. 20 c.c. of A and 10 of B are diluted for use with 30 c.c. of water. The Berlin Actien Gesellschaft have patented as developers:—The diamido naphthalene sulphonic acids prepared from α- and β-naphthylamine mono- and disulphonic acids; the amido acids from α- and β-naphthol mono- and disulphonic acids;

α - and β naphthohydroquinones, $\alpha_1\alpha_2$, $\alpha_1\beta_3$, $\alpha_1\beta_1$, and $\beta_1\beta_3$ -dihydroxynaphthalenes, and their mono- and disulphonic acids; $\alpha_1\alpha_2$, $\alpha_1\beta_1$, and $\beta_1\beta_3$ -amidonaphthols; $\alpha_1\beta_1$, and $\alpha_1\alpha_2$ -naphthylenediamines; and α -amido- β -naphthol mono- and disulphonic acids. Andresen has patented paramidophenol and cresol, and its chlorine, bromine, and iodohydroxy-derivatives. The developers are prepared by dissolving 30 grms. of the dry potassium sulphite having the formula $K_2S_2O_3$ in 100 c.c. of water, adding 10 grms. of paramidophenol hydrochloride, and then strong caustic soda till the precipitate just redissolves. One part of the solution is diluted with 5 to 50 parts of water before use.

All the foregoing substances require the addition of caustic alkali, which has several photographic disadvantages. Andresen has, therefore, patented paraphenylene and paratolylene diamine and their amido and hydroxy-derivatives. These work in the presence of alkaline carbonate or sulphite. The developing solution consists of a 10 per cent. solution of sodium sulphite containing 1 per cent. of amidoparatolylene-diamine hydrochloride. Lumière Bros. have recommended substituting for the caustic or carbonated alkali employed in the ordinary quinol developer, the tribasic sodium phosphate:—(A) quinol, 5 grms.; anhydrous sodium sulphite, 20; and water, 400 c.c. (B) Na_3PO_4 , 40 grms.; water, 200 c.c.; equal parts of each to be used.

A bromide emulsion paper with a glossy surface has lately been put on the market, and is treated in the usual manner. The polished appearance makes it unsuitable for enlargements, but it is well adapted for contact prints, especially when they are prepared by means of an automatic printing and developing machine. Patents have been taken out in Germany by J. Junk for a positive paper consisting (chiefly) of bromide of silver emulsified in a mixture of gelatin and starch. Adrianoff has given the following improved formula for "Aristo" paper:—(a) sodium chloride, 0.1 gm.; citric acid, 3; gelatin, 50 grms.; water, 500 c.c. (b) silver nitrate, 10 grms.; water, 500 c.c. *a* is warmed to 50° C., and *b* poured in slowly. The emulsion is squeezed through canvas, washed, &c., and finally coated on "barium paper" (see below). A matt surface may be obtained by the addition of starch as usual.

Complaints have been made about the inferior keeping qualities of many collodion papers, the deterioration being due to the decomposition of the silver salts. To obviate this the emulsion is spread on "barium paper"—the name given to a material which has been prepared with a layer of gelatin and barium sulphate. Liesegang has improved on this by incorporating tartaric and citric acids in the substratum, with the result that the collodion emulsion will keep its colour for months. Vollenbruch floats the back of the barium paper on a freshly prepared solution of hard gelatin, 1 gm.; sugar candy, 10; and citric acid, 18, in 1 litre of water. To avoid the curling of these papers in the different baths, Krügener paints the back with a solution of substances insoluble in water, such as nitrocellulose, shellac, &c.

Valenta has described a collodion paper in which the silver salts are the chloride, citrate, and chromate; the object of the latter being to diminish the number of different tones in the prints, so that the pictures appear to be exceptionally brilliant, and the paper becomes specially valuable for printing weak and over-exposed negatives. To prepare the normal emulsion, 200 c.c. of a 2.5 to 3 per cent. collodion are mixed with 0.36 gm. of strontium chloride and 0.18 of lithium chloride dissolved in 4 c.c. of a warm mixture of equal parts of 96 per cent. alcohol and glycerin. 1 gm. of citric acid dissolved in the minimum of alcohol is added, and the whole thoroughly shaken. In the dark room a solution of 3.2 grms. of silver nitrate in 4 c.c. of water is gradually run in, and after a further agitation the emulsion is filtered. So prepared it gives prints corresponding to ordinary paper, but by the addition of 0.4 or 0.8 c.c. of a 10 per cent. solution of chromic acid, or of 0.2 gm. of ammonium, or preferably, calcium bichromate to every 200 c.c. of the emulsion, the range of tones is considerably diminished, and it may be used for flat negatives as already mentioned. It is finished in a "combined" toning and fixing bath, containing lead nitrate 10 parts, "hypo"

200, water 1,000, to which 5 to 8 c.c. of a 1 per cent. solution of gold chloride are added just before use.

The objection to the employment of chromic acid and its salts, is that the prints lose very considerably in depth during the finishing process; and further experiments have shown that a similar emulsion, also giving abnormally hard prints, may be prepared by replacing the strontium and lithium chlorides by an equivalent quantity of cupric chloride. In this case if the prints are completely washed before toning, they only lose the usual amount, but if the washing be omitted, they are practically bleached. Tranyl chloride gives still better results; by the total or partial substitution of the chlorides mentioned, by an equivalent weight of the uranium salt, an emulsion may be made giving as brilliant prints from weak negatives as may be desired, while it loses but little in fixing, prints quickly, and tones well and uniformly in either the "combined" or the separate sulphocyanide or other gold baths in general use.

Stripping collodion papers are now being made, having a layer of gelatin between the paper and the collodion, so that by immersion in warm water the film may be removed and fixed on to any desired article.

The original "hot bath" platinum printing paper appears to be giving way to the newer "cold-bath" process, and Lainer recommends the following formula:—(A) potassium platinum chloride 10 parts, water 60; (B) ammonium bichromate 100, 10 per cent. oxalic acid solution 30, water 60. 7.2 c.c. of A are mixed with 4.8 c.c. of B, and smooth Rives paper, previously treated with gelatin or arrowroot, painted with it. To increase the brilliancy, 0.1 to 0.3 c.c. of a 2 per cent. solution of the bichromate may be added to the liquid.

A new paper requiring only immersion in water to work it, and giving white lines on a brown ground, has been introduced. It is prepared by dissolving 80 to 100 grms. of the double citrate of iron and ammonium, 10 to 20 of silver nitrate, 15 to 20 of tartaric acid, and 10 to 15 of gelatin in 1 litre of water.

For mounting purposes ordinary paste has been found useless in the case of heavy papers, and also for gelatin emulsions prepared with an "enamelled" surface, as it spoils the gloss. A large number of materials are now on the market composed of varying mixtures of starch, gum, dextrin, and gelatin dissolved in water or weak spirit, and usually containing an antiseptic, and often some glycerin to prevent "cockling" of the mount.—F. H. L.

Photographic Plates, Action of Zinc on. R. Colson.

Comptes rend. 1896, 123, 49.

A GELATIN-bromide plate placed in contact with a partly cleaned sheet of zinc and then developed, shows a deep grey tint in the part which was in contact with the cleaned surface. This is said to be due to reduction of silver bromide by zinc vapour and not to any radiation. The author concludes that if zinc be used at all in photographic apparatus it should have a compact covering through which the vapour will not pass.—A. C. W.

XXII.—EXPLOSIVES, MATCHES, Etc.

Nitroglycerin, Boiling Point of. C. A. Lobry de Bruyn. R. tr. ch. P.-B., 14, 131.

ACCORDING to Champion, nitroglycerin boils at 183° C. This figure is shown to be incorrect. As a matter of fact, ebullition was not observed even at 160° C. under a pressure of only 15 mm. The author is of opinion, however, that nitroglycerin might be distilled in a more perfect vacuum.

—H. T. P.

PATENTS.

Explosives [Safety], Impts. in the Manufacture of. G. G. André, Glenlean, Argyllshire, and C. H. Curtis, London. Eng. Pat. 23,443, Dec. 7, 1895.

A "flameless" explosive, consisting of 12 per cent. of wood-meal or similar substance, 85 per cent. of ammonium nitrate, and 3 per cent. of potassium nitrate.

The materials are incorporated in a drum with wooden balls without the addition of any liquid.—R. B. P.

Safety Explosives, Impts. in the Manufacture of. R. Pierre, Brefeld, and W. Pottgiesser, Königshof, both in Barmen, Germany. Eng. Pat. 6,555, March 25, 1896.

An explosive, consisting of 93 parts of ground ammonium nitrate, 5 parts of "aniline nitrate," and 2 parts of dioxide of manganese, lead, or chromium, intimately mixed together. —R. B. P.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS, ETC.

Nitrogen Determinations, A New Safety Distillation Tube for Rapid Work in. C. G. Hopkins. J. Amer. Chem. Soc. 1896, 227—228.

THE tube shown in the figure is made from tubing about 7 to 8 mm. internal diameter. The side openings A and A' should be nearly as large, and the bulb about 5 cm. in

diameter. The length of the tube below the bulb is 12 cm., and that above the bulb about the same. The jets C and C' are 2 mm. inside diameter. In use, the tube is pushed through the cork of the distilling flask until the opening A' is below the cork; the vapour then passes through the side openings, and whatever condenses in the tube below the bend B runs back into the flask through the jets C and C', which always remain filled with liquid. —L. A.

Gas Analysis, Apparatus for. O. Bleier. Ber. 29, [11], 1761—1762. (See also Ber. 28, 2423; 29, 260, this Journal, 1896, 294.)

THE apparatus described by the author (*loc. cit.*) may be conveniently modified, to permit of the attachment of another series of absorption pipettes, by providing a vertical branch on the horizontal pipe just in front of the last three-way tap, which branch may be closed by means of a piece of india-rubber tubing and a glass rod, when not in use. Another modification consists in affixing a third and fourth gas pipette, filled respectively with ammoniacal and hydrochloric cuprous chloride, the latter for absorbing the final traces of carbon monoxide and ammonia vapour.

In place of the Hempel pipette, it is proposed to use a simpler form, the capillary tube of which can be filled with liquid by pressing a caoutchouc bulb attached to the filling tube. The pipette can then be affixed to the above-named branch on the main apparatus by a connecting piece of capillary glass tube with india-rubber connections.

Blowing into the pipette for filling, and the necessity for filling the connecting piece with water, are thus dispensed with. —C. S.

INORGANIC CHEMISTRY.—QUALITATIVE.

Phosphorus, Spectrum of, in Fused Salts and Metallurgical Products. A. de Gramont. Comptes rend. 1896, 122, 1534—1536.

SPARKS are passed between two fragments of minerals or fused salts connected to the poles of an induction coil, and also to a condenser. Under these circumstances the spark spectra exhibit not only the characteristic lines of the metals but also of the metalloids. Thus, fused phosphates (of soda and potash) give a fine spectrum of lines of phosphorus. Of these the most easily distinguished, by their position and appearance, are the triplet Pa (wave lengths 604.2, 603.45, and 602.5) in the red, and the doublet Pe (wave lengths 460.3 and 458.85) in the blue. These characteristic lines are also distinctly shown by certain meteorites and by metallurgical products in which phosphorus is combined with iron or copper. —D. E. J.

Nitrites, Detection of, by Means of Cuprous Compounds. P. Sabatier. Comptes rend. 1896, 122, 1417—1419.

CUPROUS oxide, in contact with a solution of silver nitrate, entirely displaces the silver, and finally a grey substance is obtained (Rose, *Annal. Pogg.* 1857, 101). This contains a cuprous, or cupro-cupric nitrate, and when treated with an excess of strong sulphuric acid gives a magnificent blue-violet coloration, which is at once destroyed by water, and disappears spontaneously after some days.

The colour is readily obtained by adding cuprous oxide to a solution of sodium nitrite in strong sulphuric acid. All cuprous and cupro-cupric compounds give the reaction, but not immediately in the case of the chloride and iodide. Metallic copper also gives the reaction, finely powdered (reduced) copper immediately, shavings gradually. Cupric, mercurous, mercuric, lead, silver, stannous, stannic, manganese, cobalt, and nickel compounds give no reaction.

The violet colour is quickly destroyed by oxidising agents as nitric and persulphuric acids, and by agitation in dry air. Water containing one-fifth its bulk of sulphuric acid does not destroy the colour.

To detect nitrous acid, a drop of the solution, on a white plate, is mixed with a drop of strong sulphuric acid, and a few grains of cuprous oxide added. The violet coloration will be produced in solutions containing only $\frac{1}{50}$ mol. of nitrous acid per litre.

The violet compound is cupric nitrosodisulphonate.

—N. H. J. M.

INORGANIC CHEMISTRY.—QUANTITATIVE.

Ammonium Molybdate Solution, Modified, for Analytical Purposes. A. L. Winton. J. Amer. Chem. Soc. 1896, 18, [5], 445—446.

1. DISSOLVE 1,000 grms. of molybdic acid in 4,160 c.c. of a mixture of ammonia (sp. gr. 0.90), one volume, water, two volumes.

2. DISSOLVE 5,300 grms. of ammonium nitrate in a mixture of 6,250 c.c. of nitric acid (sp. gr. 1.42) and 3,090 c.c. of water.

ADD 1 to 2 slowly with constant stirring, allow to stand for a few days in a warm place, and decant the clear liquid. This solution has the composition recommended by Fresenius, but contains in addition 15 grms. of ammonium nitrate in every 50 c.c. —H. T. P.

Iodine Compounds, Soluble; A New Method for Titration of. E. Riegler. Zeits. Anal. Chem. 1896, 35, [3], 305—307.

THE principle of this method consists in liberating the iodine in an iodide by means of iodic acid, removing the iodine by agitation with petroleum ether, and then estimating the excess of iodic acid by titration with decinormal sodium thiosulphate solution. The reactions are given in the following abstract. The iodic acid is employed in the form of a decinormal solution, which is obtained by dissolving 17.6 grms. to 1,000 c.c. —A. K. M.

*Titration of Thiosulphate Solution with Iodic Acid.*E. Kieglér. *Zeits. Anal. Chem.* 1896, **35**, 308.

THE reaction involved depends upon the following equation—

A solution of starch is used as indicator, and is added to the thiosulphate solution. The addition of the slightest excess of iodic acid produces a blue coloration, owing to the liberation of iodine, which is brought about in accordance with the following reaction:—

Iodic acid is readily obtained in a state of absolute purity, and merely requires to be dried over sulphuric acid.

—A. K. M.

*Nitrous Acid, Estimation of Minute Quantities of.*L. Zambelli. *Monit. Scient.* 1896, **10**, 351.

THE author refers to a paper by Lunge and Lwoff (this Journal, 1895, 67; also *Monit. Scient.* 1895, 117), in which a colorimetric method of the author's is mentioned. He points out that he has described two methods, and that he has given the preference to the one which Lunge and Lwoff have ignored. The method advocated is the following:—2 grms. of sulphamic acid and 2 grms. of phenol are dissolved in 50 c.c. of dilute sulphuric acid (equal vols. of acid and water). A measured quantity of the solution to be tested is introduced into a flask, 2 or 3 c.c. of the above solution added, and the flask is well shaken. At the end of 10 to 15 minutes the solution is made just alkaline by the addition of ammonia, and if nitrous acid be present a yellow coloration will be produced. The colour has to be matched by repeating the reaction, using in this case, however, a standard solution of silver nitrite. Results are given showing the accuracy of the method which the author also recommends on account of its simplicity.—A. K. M.

Hydrofluoric Acid, Volumetric Analysis of: Some Applications of the Acid. K. F. Stahl. *J. Amer. Chem. Soc.* 1896, **18**, [5], 415—425.

COMMERCIAL hydrofluoric acid always contains as impurities, hydrofluosilicic and sulphuric acids—introduced during the process of manufacture—owing to the disturbing influence of which the specific gravity of the acid is only a rough index as to its real strength. The following method for determining these impurities, as well as the percentage of hydrofluoric acid, is stated to be rapid and reliable.

1. *Total Acids.*—2 grms. of the sample are added to a measured volume (25—50 c.c.) of normal NaHO, sufficient to neutralise almost the whole of the acid. A few drops of alcoholic phenolphthalein are now added, the solution heated to 50° C., and the titration completed as usual.

2. *Hydrofluosilicic Acid.*—2 grms. are diluted in a platinum dish with 5 c.c. of water, and partially neutralised with potassium carbonate (0.65 grm. K_2CO_3 for each 1 c.c. of normal NaHO used under 1). 15 c.c. of 50 per cent. spirit are then added, followed by sufficient absolute alcohol to elevate the alcohol content of the whole to 50 per cent. After one hour, the gelatinous precipitate of K_2SiF_6 is filtered off, washed with 50 per cent. alcohol, transferred (including filter-paper) to a platinum dish, warmed to 50° C. with 25 c.c. of water, and slowly titrated with normal NaHO and phenolphthalein.

3. *Sulphuric Acid.*—4 grms. of sample are evaporated in a platinum dish on the water-bath, until acid fumes are no longer evolved. The syrupy residue of H_2SO_4 is diluted, and titrated with alkali.

In calculating out results it must be noted that—

Amongst the more recent commercial applications of hydrofluoric acid, its employment in dilute solution (1—2 per cent. HF) for cleaning iron castings from sand and scale has found great favour. It is stated to be, for this purpose, far superior to sulphuric acid, being more rapid, uniform, and thorough in its action.—H. T. P.

Carbonic Acid, Rapid Determination of, in Air and Confined Spaces. M. Henriot. *Comptes rend.* 1896, **123**, 125.

THE sample is taken in a six-litre flask provided with a tap funnel and tube with stop-cock passing through the cork. In the laboratory the flask is cooled, 15 c.c. of potash (8 grms. to the litre) coloured with phenolphthalein, and 2 c.c. of ether are placed in the funnel, the latter to protect the potash from the air. The potash is washed into the flask with boiled water, and then well shaken; after standing an hour, standard acid is added to complete decolorisation. Twice the difference between the acid so required and that needed to neutralise 15 c.c. of the potash is equivalent to the carbonic acid in the sample, since bicarbonates are neutral to phenolphthalein.—A. C. W.

Pyrites, Determination of Sulphur in. T. S. Gladding.*J. Amer. Chem. Soc.* 1896, **18**, [5], 446—449.

THE author shows by direct experiment that—

1. When the whole of the barium chloride is added at once (as Lunge directs) the barium sulphate carries down with it a proportion of barium chloride equivalent to about 0.5 per cent. of the sulphur present.

2. The occlusion of barium chloride is almost entirely prevented if the reagent be added (as the author recommends) drop by drop from a burette to the solution of the ore.

3. The solubility of barium sulphate in the acid liquid of precipitation, is so small that the loss due to it amounts only to about 0.02 per cent. of sulphur. Lunge's claim, therefore, that in his method the occlusion of barium chloride is almost exactly compensated by the solubility of the precipitate, is shown to be inaccurate. *Per contra*, the results obtained by the process must be too high by several tenths per cent. As regards the trace of sulphur (0.20 to 0.10 per cent.) occasionally carried down with the ferric hydrate precipitate, the author maintains that it may be accurately determined by dissolving the precipitate in hydrochloric acid, and precipitating with barium chloride.

—H. T. P.

Gold Solvents, Estimating the Efficiency of. W. J. Sharwood. *Eng. and Mining J.* 1896, **61**, 613.

IN testing cyanide and other solutions, as regards efficiency in dissolving gold, the real object is to find the weight dissolved from a given area in a given time. A better way when comparing different solutions is to find the time required to dissolve a layer of gold of known thickness.

The author gives the following method:—Ordinary microscope square "cover glasses" are carefully cleaned and coated on one side with an alcoholic solution of shellac. When most of the alcohol has evaporated off, the glasses are pressed upon a perfectly smooth sheet of gold leaf. The shellac is allowed to harden, and the ragged edges of the gold leaf are then rubbed off. In taking gold leaf from the book, it should not be removed from the paper, but cut out bodily and laid on a smooth surface. The test-pieces of metal thus produced are of uniform weight and thickness, so that the results obtained by noting the time taken by different solvents to effect complete solution are strictly comparable. The test-pieces should be kept on edge when immersed in the solvent.

The author found by repeated trials that the thickness of gold leaf in two books used was very uniform, and that the variation in the weight of sheets of equal size was less than 0.25 per cent.—A. S.

*Silver from Gold, Separation of, by Volatilisation.*J. W. Richards. *J. Franklin Inst.* **141**, [846], 447—451.

IN the blow-pipe assay of gold and silver, where the button of precious metal is too small for weighing, and its weight has to be calculated from an accurate measurement of its horizontal diameter, it is found that the gold and silver may be parted on charcoal by oxidation and volatilisation. The charcoal must be dense so as not to burn away too quickly, and should leave a white ash. The button is heated in a sharp-pointed oxidising blow-pipe flame to a bright yellow heat, but not to whiteness, when the silver volatilises easily and steadily until there is less than 5 per cent. of it remaining in the gold. The temperature is estimated at 1,100° to

1,200° C., or a little above the melting point of copper. To remove the remainder of the silver the temperature is now raised to 1,500° C., when the silver is entirely eliminated, and the gold also begins to volatilise. The last fact is indicated by a faint crimson coating on the charcoal ash close to the button and there is a trace of gold lost which, however, is immeasurable. The flame to be used is a very sharp-pointed needle-like oxidising one, about 1 cm. in length to the blue tip, and the button should be brought to within about 1 or 2 mm. of this visible blue tip. If the alloy on starting, be white, it is found that after three to six minutes of this treatment, it has become pale yellow. When it exhibits a brass yellow colour, the heat should be raised for two minutes, when the gold colour will appear but without the crimson coating. After this, one minute at a white heat will complete the separation. The gold button is then taken out, expelled, and measured.

It was suggested that the method might be practicable if an electrically-heated furnace could be devised in which the gold and silver buttons could be placed on suitable supports and kept at the proper temperature with a current of air passing over them. The movement to the hottest part of the furnace would suffice to remove the last traces of silver, just as the last traces of lead are removed in cupellation in an ordinary muffle.—A. W.

Zinc Analysis by Electrolysis. E. Jordis. Zeits. für Elektrochemie, 1896, 2, [30], 655—657.

THE objections have been raised against the electrolytic method of estimating zinc that:—(1.) The deposition of copper upon the platinum dish takes time. (2.) About two hours are required for the deposition of 0.12—0.2 gram. of zinc. (3.) The edges of the deposit soon oxidise or become dissolved. (4.) In general, the zinc can only be separated from other metals by chemical processes. The author shows how the first three objections are overcome. The dish must be coppered to a height of about 2–3 mm. above that at which the zinc solution will stand; thus, if 250 c.c. of zinc solution are to be used, 250 c.c. of copper solution must be taken. If the zinc solution be properly made up, there is no risk of the precipitated zinc redissolving. It should contain not less than 0.3—0.5 gram. of zinc, and is prepared for electrolysis by adding to the neutral solution 2 grms. of ammonium sulphate and 5–7 grms. of ammonium acetate and acidifying with a few drops of lactic acid. After the current has been passing for about 25 minutes the electrolyte should be nearly neutralised with ammonia. A saturated solution of copper sulphate with 5 per cent. of nitric acid may be used; or else a solution of the double oxalate of copper and ammonia in oxalic acid. When the electrolyte is stirred and a moderately high current-density is used, about 85 per cent. of the zinc is deposited in 35 minutes, and about 96 per cent. of it in an hour. The deposition of the remainder of the zinc can be accelerated by pouring the solution out into a fresh coppered dish and finishing the electrolysis in this. If this be done from 40 to 60 minutes after the start, the whole analysis only takes about 1½ hour. (See this Journal, 1896, 280—281; also 379.)—D. E. J.

Ammonium Citrate Solution, used in the Analysis of Fertilisers, A Simple Method for Determining the Neutrality of. N. W. Lord. J. Amer. Chem. Soc. 1896, 18, [5], 457—458.

A QUANTITY of distilled water is distinctly coloured with purified litmus, and a portion of the solution is further diluted with its own volume of water. Two Nessler jars are filled with the weaker solution, and a trace of sulphuric acid is added to one, and of ammonia, to the other. The jars when placed one behind the other and viewed by transmitted light furnish a standard neutral tint with which is compared a third Nessler jar charged with the stronger litmus solution plus 5 c.c. of the ammonium citrate under examination. The slightest deviation of the citrate from neutrality may thus be perceived, and its amount determined by cautiously adding semi-normal acid or ammonia to the single jar until the two tints are exactly equal. A corresponding correction having been applied to the bulk of the citrate solution, the latter should be again tested to make sure that exact neutrality has been attained. The process

is simple; and solutions thus neutralised have always been found correct when tested by Hutton's method (with alcoholic calcium chloride solution).—H. T. P.

Silica, Analytical Determination of, Notes on. F. G. Wiechmann. School of Mines Quart. 1896, 17, [3], 220—225.

THE following analytical scheme is given for the determination of total silica, silicates soluble in water, crystalline silica and silicates insoluble in caustic potash solution (1 : 4), and amorphous silica (diatomaceous earth).

Total Silica.—Mix $\frac{1}{2}$ gram. with 10 grms. of mixed carbonates of sodium and potassium (1 : 1), fuse, dissolve in dilute hydrochloric acid and proceed as usual.

Silica Soluble in Water, &c.—Boil 1 gram. with 100 c.c. of water for half-an-hour, filter, and wash with boiling water. Acidify the filtrate and washings with hydrochloric acid, evaporate to dryness and proceed as usual. Wash the residue from the treatment with boiling water into a beaker with the least possible quantity of water, and boil it with 100 c.c. of caustic potash solution (25 per cent.) for one hour; filter and wash with hot water. This filtrate is evaporated with hydrochloric acid for determination of the amorphous silica, while the residue on the filter is dried and fused with the mixed carbonates for determination of the crystalline silica and silicates insoluble in caustic potash solution.—A. G. B.

ORGANIC CHEMISTRY.—QUALITATIVE.

Alkalimetry, Resazurin as an Indicator in. L. Crismer. Bull. de l'Assoc. Belge des Chimistes 10, [1], 22—24.

RESAZURIN is capable of detecting the presence of smaller quantities of acid than are revealed by litmus. It may be prepared by adding 8 grms. of fuming nitric acid to a solution of 10 grms. of resorcinol in 500 grms. of ether cooled down to -5 or -8° C. After leaving at rest for two days in the cold, the resulting crystals are collected, washed, and purified by means of sodium carbonate, which produces red-brown crystals of the sodium salt of resazurin, that of resorufin remaining in solution. After washing the crystals with sodium carbonate solution (concentrated), resazurin crystals may be obtained by slightly acidifying the aqueous solution of the sodium salt with sulphuric acid. The test solution consists of 0.20 gram. of resazurin dissolved in 40 c.c. of decinormal ammonia and made up to 1 litre with water. This $\frac{1}{5000}$ solution is very stable, and of an intense blue shade (rose by transmitted light), turning red in presence of acid, two or three drops being sensitive to one of decinormal sulphuric, hydrochloric, or oxalic acid, and conversely, ammonia, alkalis, or borax. It may, therefore, be employed as an indicator for the latter substance, for which purpose litmus and phenolphthalein are unsuitable; on the other hand, resazurin gives only uncertain results with nitric acid and monobasic organic acids, but is in common with litmus and phenolphthalein—though within more restricted limits—susceptible to the action of carbon dioxide. By the action of reducing agents resazurin, in alkaline solution, is converted into resorufin, and it is therefore advisable not to prepare resazurin test papers until just before use.

An idea of the sensitiveness of this indicator is afforded by the fact that the acid solution will detect the alkali dissolved by heating water (200—300 c.c.) in a flask of Jena glass even before the point of ebullition is attained.—C. S.

Sandmeyer's Reaction. J. Walter. J. prakt. Chem. 1896, (2), 53, 427—430.

THE author supposes that the conversion of diazobenzene chloride into chlorobenzene by the action of cuprous chloride takes place in two stages: (1) reduction to phenyl hydrazine, the CuCl being oxidised to CuCl_2 ; (2) oxidation of the phenyl hydrazine to chlorobenzene, CuCl being reformed. That a trace of CuCl does not suffice to bring about the reaction may be due to its mechanical enclosure by the oily chlorobenzene. Where soluble sulphonic acids are used, a very small quantity of cuprous chloride is, according to G. Tobias (Ber. 23, 1629; this

Journal, 1890, 824) sufficient. To test his view the author tries the action of CuCl_2 on phenylhydrazine in presence of hydrochloric acid and 16 grms. of chlorobenzene were obtained from 36 grms. of phenylhydrazine. Since the reaction might have consisted of an oxidation of the phenylhydrazine to diazobenzene and subsequent formation of chlorobenzene from this in the usual way, he tried the action of ferric chloride, because, according to Sandmeyer, ferrous chloride produces no chlorobenzene by its action on diazobenzene; 14 grms. of chlorobenzene were obtained from 27 grms. of phenylhydrazine. Attempts to demonstrate the formation of phenylhydrazine by the action of cuprous chloride on diazobenzene were unsuccessful. Dihydroxy-tartaric acid is recommended as a very delicate reagent for phenylhydrazine, producing a yellow precipitate or coloration in solutions containing 1 part of the hydrazine in 10,000 parts of water. It is suggested that the conversion of chlorobenzene into iodobenzene by hydriodic acid alone, is due to its reducing properties, the reaction being similar to that taking place with cuprous chloride.—T. E.

Benzonaphthol, Some Reactions of. A. Christomanos. Chem. Zeit. 1896, 20, 583.

BENZONAPHTHOL (β -naphthol benzoic ester) is at the present time used in medicine in preference to β -naphthol, and the author proposes the following test as delicate and characteristic.

Benzonaphthol dissolves, in the cold, in about three times its weight of conc. sulphuric acid, with the formation of a pale yellow colour. On warming the solution, the colour darkens until, at about 200 °C., it becomes a dirty violet-red, the solution at the same time exhibiting a green fluorescence. The fluorescence persists on dilution, but the diluted solution thickens on cooling, with separation of crystalline flakes which redissolve on warming. Addition of ammonia solution to the strongly diluted solution obtained by heating with sulphuric acid, produces a very intense and permanent bright bluish green fluorescence similar to that given by fluorescein or aesculin. This fluorescence is not given by any phenol ester but is produced by traces of the benzonaphthol.

Boiling benzonaphthol with caustic soda solution, diluting with water and acidifying with concentrated hydrochloric acid causes the solution to assume a rose coloration on cooling. The addition of a few drops of concentrated nitric acid hastens the appearance of the colour, making it faint cherry red.—J. T. C.

Dimethyl-m-amidophenol, Reactions of. L. Lefèvre. Bull. Soc. Chim. 1896, 15, 900.

See under IV., page 584.
(Also this Journal, 1895, 992.)

Textiles [Testing Army Cloth], Chemical Technology of: Report on Progress made during 1895. O. N. Witt and A. Buntrock. Dingl. polyt. J. 300, 185.

See under VI., page 589.

Tussah Silk, the Examination of, in Textile Fabrics. F. Filsinger. Chem. Zeit. 20, 324.

THE cross-section of the Tussah fibres is larger and flatter than that of ordinary silk, and shows many fine air-tubes. Moreover, characteristic bands frequently cross the fibres in an oblique direction, the fibres thereby approaching cotton fibres in their microscopical appearance. The Tussah fibres are not soluble in basic zinc chloride, concentrated hydrochloric acid, and other reagents in which ordinary silk is readily dissolved. Finally, Tussah silk is more inflammable than ordinary silk.—H. S.

Butter, Detection of Borax in. Planchon and Vuattart. J. de Pharm. et de Chim. 1896, 4, [2], 49—51.

TWENTY grms. of the butter are melted and dissolved in petroleum spirit. The solution is poured into a separating funnel with the rinsings of the basin, which is rinsed once with 10 c.c. of petroleum spirit and twice or three times with 10 c.c. of water. After shaking and settling, the aqueous portion and any supernatant film are run into a platinum basin, evaporated and incinerated. The ash is fused

with 0.5 gram. of potassium carbonate, a trace of copper oxide added, and the mass again fused. Borax shows itself by a greenish-blue or violet-blue coloration; whilst the residue from a pure butter is grey or reddish-grey. The only other substances which give a reaction at all similar to borax are silicates, and they are never likely to occur in such circumstances. The method allows the detection of 2 parts of borax in 1,000 of butter, or a still smaller proportion if a larger amount be taken for analysis. The same method has not proved very satisfactory for the detection of borax in wine, beer, or milk.—J. T. D.

Red Wines, Detection of Foreign Colouring Matters in. A. Belar. Zeits. Anal. Chem. 1896, 35, 322—323.

AN addition of rosaniline to wine may be readily detected and the amount estimated by agitating about 5 c.c. of the wine with an equal volume of nitrobenzene. Methylene blue imparts a green colour to nitrobenzene, whilst rosaniline, purpurin, and safranin are taken up by and dissolve in it, without change of colour. Eosine imparts a wine-red colour whilst indigo carmine is insoluble in nitrobenzene and, in fact, behaves like the blue colouring matter of plants. The experiments are being continued with other dyes.—A. K. M.

Wood Cellulose in Paper, Testing of. Leipzig Paper Testing Inst. Papier Zeit. 1896, 44, 117.

THE whiteness of cellulose pulp is no indication of its purity. A white unbleached wood pulp may contain a less pure cellulose fibre than one of a darker colour. Upon the assumption that the durability of wood pulp papers depends upon the purity therein of the cellulose fibres, a means of testing such papers was desirable. It has been found that aniline dyes are most suitable for this purpose. Good bleached wood cellulose is not coloured in the least by a solution of aniline, but unbleached wood fibres, prepared either by the sulphite or soda process are turned to a distinct bluish green colour. The less pure the cellulose, the more dense is the greenish hue, and this is more pronounced with fibre prepared from wood cut in the autumn, when the reaction with the aniline is similar to that obtained with mechanical wood pulp. Should the sample of pulp remain uncoloured after adding the aniline solution it is safe to assume that fibre of such purity could only have been obtained on a practical scale by bleaching. The aniline colour employed is that known as Malachite green. It should be dissolved in water containing 2 per cent. of acetic acid. The action upon the fibres is very rapid and the colour cannot be removed by washing and even soaking in water for several weeks. If the sample to be tested be composed simply of wood cellulose, the examination can be made with the naked eye, but with a sample of paper in which other materials are present, it is necessary to disintegrate the web and examine a portion under the microscope. The paper may be prepared for the microscope by boiling in a 1 per cent. solution of soda, providing the fibres are afterwards rapidly washed free from alkali on a very fine wire gauze filter. A small quantity of the prepared fibre is placed upon a slide under the microscope and a drop of the dye solution then added. Rosaniline sulphate also serves to distinguish between wood pulps prepared by the sulphite and the soda processes. A saturated solution is prepared to which is added a little alcohol and then sulphuric acid, until the carmine-red solution shows a faint violet shade. When the cellulose fibre is placed in such a solution, the following colours are imparted:—(1.) Unbleached sulphite fibres turn to a deep violet red. (2.) Bleached sulphite fibres turn only slightly red with only a very faint shade of violet. (3.) Unbleached soda pulp becomes still less coloured than bleached sulphite. (4.) Bleached soda pulp assumes but the faintest tinge of red, and under the microscope the fibres prepared from summer-cut wood are practically colourless, whilst those prepared from autumn-cut wood are occasionally slightly coloured, the colour being mainly due to the presence of medullary cells. As regards bleached sulphite and unbleached soda fibres, any difficulty of distinction by other reactions may be settled by the Malachite green test.—S. P. E.

Dulcine (Sacrol), Detection of, in Beverages. Jorissen. *Revue Chim. Ind.* 1896, **7**, [77], 134—135.

This substance, which resembles saccharine in its sweetening powers, and is sometimes used for adulterating foods, was discovered by Berlinerblau in 1885, and has the composition $\text{NH}_2\cdot\text{CO}\cdot\text{NH}\cdot\text{C}_6\text{H}_4\cdot\text{O}\cdot\text{C}_2\text{H}_5$. It may be readily detected as follows in a beverage.—About one-twentieth of its weight of plumbic carbonate is added to the liquid, and the whole evaporated to a syrupy consistency. The syrup is then extracted with alcohol, the alcohol distilled off, the residue extracted with ether, and the ether evaporated off; the residue then contains the dulcine. Mercuric nitrate free from excess of acid is prepared by dissolving 1—2 grms. of precipitated yellow mercuric oxide in dilute nitric acid, adding caustic soda till a permanent precipitate just forms, diluting with water to 15 c.c., allowing to stand, and decanting the clear liquid. The residue to be tested for dulcine, is suspended in about 5 c.c. of water, 2—4 drops of the nitrate solution are added, and the test-tube containing the mixture is introduced into a water-bath for 5—10 minutes. The solution will then have assumed a more or less marked violet tint. A small quantity of plumbic dioxide is added, when a brilliant violet coloration is produced. A centigram. of dulcine gives a very strong reaction, a milligram a visible, though faint one. Neither saccharine, benzophenol, urea, nor sugar give this reaction, which is more certain than Morpurgo's reaction.—L. T. T.

Methylamines, New Method for the Separation of. M. Delépine. *Bull. Soc. Chim.* 1896, 701—704.

THE method depends on the fractional separation of the compounds of formaldehyde with mono- and dimethylamines, whilst trimethylamine does not combine. Mono-methylamine gives the compound $\text{CH}_2\cdot\text{N}(\text{CH}_3)$, boiling at 166° C., and dimethylamine forms either $\text{CH}_2\cdot[\text{N}(\text{CH}_3)_2]_2$ or $\text{HO}\cdot\text{CH}_2\cdot\text{N}(\text{CH}_3)_2$, both of which boil at 80°—85° C. The boiling point of trimethylamine being 90° C., the fractions are easily separated. As a matter of fact, the fraction containing the dimethylamine boiled at about 67° C., owing to the presence of methyl alcohol in the formaldehyde employed, which formed a molecular compound with the condensation product. The bases are regenerated by saturating aqueous solutions thereof, boiling at 166 or 167° C., with pieric acid. On evaporation, the pierates of mono- or dimethylamine crystallise out. The former melts at 207° C. and the latter at 156° C. In place of using the pierates, the compounds may be decomposed by the prolonged action of hydrochloric acid and alcohol, when, on evaporating the solutions, the hydrochlorides of the bases are obtained. Methylamine hydrochloride crystallises in mother-of-pearl plates, melting at 210°—220° C., whilst dimethylamine hydrochloride forms long prisms, melting at about 171° C., and much more easily soluble in water or alcohol than either methyl- or trimethylamine hydrochloride. In some cases it is advantageous to employ bis-muth iodide for separating the base from the fraction, boiling at 166° C. Methylamine forms red hexagonal plates of the formula $(\text{CH}_3\text{NH})_2\cdot 2\text{BiI}_3$, from which the base can be obtained by boiling with potash or soda.

Finally, Nessler's solution gives an insoluble, yellowish, flocculent precipitate with methylamine, whilst di- and trimethylamine give white precipitates soluble in water, and hence this reagent serves as a test for the purity of a given trimethylamine.—T. A. L.

Fats and Oils, Vegetable and Animal; The Determination of the Solid Fat in Artificial Mixtures of. J. H. Wainwright. *J. Amer. Chem. Soc.* 1896, **18**, [3], 259—264.

"Compound lard" or "lard compound" has in recent years become an important article of commerce, and consists

essentially of cotton-seed oil and oleostearin made from beef fat mixed in different proportions, sometimes containing a proportion of genuine lard. Attempts to deduce the percentage of oleostearin in the mixture from determinations of the ordinary "constants" being unsatisfactory, the following simple process was devised:—

About 150 grms. of the sample are melted in a beaker at 212° F. The substance is then allowed to cool to from 75°—80° F. After standing for 12 hours longer in a moderately warm place, the solid fat commences to crystallise. The solid (crystallised) contents of the beaker having been thoroughly mixed by stirring, 50 grms. are carefully wrapped in flannel and subjected to pressure in a screw press. The pressure should be applied very gradually, especially at first, and continued until the greatest pressure obtainable has been exerted. Usually at least one hour is required. The cake of solid fat is then detached from the cloth and weighed. The results of numerous assays of known mixtures show that the method is reliable within about 1½ per cent., the extreme errors in 13 experiments, in which the proportion of oleostearin added varied from 19.6 to 29.2 per cent., being — 0.8 and + 1.6 per cent.—L. A.

Tannin, Estimation of. B. Weiss. *Der Gerber*, 1896, **22**, 62—64.

COMMENTING on Cerych's paper (this Journal, 1896, 51) the author says that he has evidence that the insoluble matter left when the Mitrowitz oak-wood extract is dissolved, is not ellagic acid alone, but contains also a metallic compound of tannin, which is not so insoluble as

ellagic acid is. He agrees with Cerych that it is essential to use a constant weight of extract dissolved in a constant volume of water, and to work at the same temperature; these points, however, he claims to have already insisted upon himself. It is shown that hide powder, which has been washed and dried as recommended by Cerych again yields a solution which gives a turbidity with tannin when soaked in water, as though the hide fibre were converted into gelatin by the action of water at the ordinary temperature. This is to some extent prevented by treating the hide powder with an antiseptic such as lysol or mercuric chloride.

The author approves of Cerych's suggestion to mix filter paper with the hide powder, and proceeds as follows:—35 grms. of pure unsized filter paper are pulped in 2 litres of a 2 per cent. lysol solution; to this 100 grms. of hide powder are added and allowed to remain for several hours. The mass is drained on a funnel, pressed, and treated, once with pure water, once with dilute alcohol, and once with strong alcohol. The mixed powder and paper are allowed to dry overnight, powdered, and 6½—7 grms. thereof are packed in the filter tube so that the moistening of the powder and the filtration of the tannin solution may be completed in 2—3 hours.—A. G. B.

Glue, Valuation of. C. Stelling. *Chem. Zeit.* 1896, **20**, 461—462.

IN view of the difficulties met with in the direct determination of chondrin and gelatin, the non-gelatinous constituents of commercial glue are estimated. To this end, 15 grms. of the glue to be tested, are placed in a 250-c.c. flask, covered with 60 c.c. of water, and left for 12 hours. The flask is next heated on the water bath till complete solution of the glue is effected. The water evaporated from the flask, in accomplishing this, having been replaced, the flask is filled almost to the mark with "alcohol of 90°," allowed to cool, and then filled to the mark and well shaken. It is then placed aside for 6 hours, after which the liquid is filtered, 25 or 50 c.c. of the filtrate are evaporated to dryness, and the residue is dried at 100° and weighed. The method yields only approximately accurate results, but is trustworthy and useful for comparative tests.

The following are some of the results obtained:—Gelatin (5 samples) contained on an average 3.39 per cent. of non-gelatinous compounds; bone-glue (from bones treated with hydrochloric acid, first extract) (4 samples), 10.33 per cent.; bone-glue (obtained under pressure with the use of

little or no acid) (17 samples), 20.66 per cent.; glue employed for clarifying wine (2 samples), 33.2 and 59.3 per cent.—E. B.

Sugar House Analysis, Two Sources of Error in. E. C. Shorey. J. Amer. Chem. Soc. 1896, 18, 162.

See under XVI., page 603.

Malt, Estimation of Diastatic Power in. W. G. Sykes and C. A. Mitchell. Analyst, 1896, 21, 122—128.

In order to obtain a diastatic value in one operation, the authors have devised a method which to some extent combined the methods of Kjeldahl and Lintner. Into a wide-mouthed 200-c.c. flask are placed 100 c.c. of a 2 per cent. solution of soluble starch, and 1 c.c. of the filtered extract, prepared by digesting 25 grms. of ground malt with 500 c.c. of water for six hours at the ordinary temperature. The whole is well shaken and allowed to stand at a temperature of 70° F. for one hour; 50 c.c. of Fehling's solution are then added and the flask covered by a watch-glass, placed on wire gauze over a Bunsen flame and heated to 98° C. It is then removed from the flame and immersed in boiling water for seven minutes. It has been found experimentally that by this procedure the contents of the flask are submitted to conditions of temperature and time closely approximating those employed in Lintner's method. The cuprous oxide is collected in a Soxhlet's filter tube, reduced in hydrogen, and weighed. The weight of the copper found, divided by 0.458 (the quantity of copper contained in 50 c.c. of Fehling's solution) and multiplied by 100, gives the diastatic power.

—J. L. B.

Malt, A Method for the Determination of the Diastatic Capacity of. A. R. Ling. J. Fed. Inst. Brewing, 1896, 2, 335—346.

AFTER giving a résumé of researches on which the present methods of estimating diastatic power are based, the author describes the following method:—A determination is first of all carried out by Lintner's method, and those tubes in the series are selected in which reduction is almost complete, the contents are transferred to a boiling flask and the unreduced Fehling's solution titrated with a solution of glucose of known titre, containing conveniently 2 grms. per litre, potassium ferrocyanide being used as indicator. The necessity is pointed out of taking the contents of the tubes for titration which are nearly reduced. If tubes showing slight reduction are selected, erroneous results are obtained. The diastatic power can be calculated by the formula $DP = \frac{100(5-y)}{5x}$ in which x represents the volume in c.c. of normal malt extract taken, and y the volume in c.c. of unreduced Fehling's solution found by titration. This method obviates the preparation of a second series of tubes, and by means of it two or three concordant values may be rapidly obtained from the first series of tests.—J. L. B.

Barley and Malt, Phosphoric Acid in. A. Fernbach. J. Fed. Inst. Brewing, 1896, 11, 128—140.

THE author has examined samples of a number of barleys, and of the malts obtained from the same barleys, and in each he has determined both the total and the soluble phosphoric acid. The analyses were made on the basis of the 1,000 corns method, so that the results obtained with any given malt were strictly comparable with those yielded by the corresponding barley. For the determination of the soluble phosphoric acid in a malt, the author makes use of the hot mash; he adds a little yeast to remove as much saccharine matter as possible, and the whole is then evaporated and incinerated. A similar method is adopted in the case of barley, the saccharification being brought about by the addition of malt, which is of course allowed for in the calculation. The main fact which is brought out by the results given is, that a remarkable amount of phosphoric acid is converted into a soluble form during the malting process. As an example, the following may suffice:—In a barley containing 9.66 total P_2O_5 , the soluble P_2O_5 amounted to 4.44, or 45.96 per cent. of the total. The malt obtained from this barley contained 8.46 total P_2O_5 , and 6.87 (or 80.99 per cent. on total) of soluble P_2O_5 .

This change is attributed to the formation, during germination, of acids which act upon the secondary and tertiary phosphates of lime and magnesia, transforming them into soluble primary phosphates. In the case of one barley, 97 per cent. of the phosphoric acid was in a soluble form, whilst in the corresponding malt only 83 per cent. was soluble. This result is attributed to the hardness of the steeping water, which would bring about the precipitation of the phosphoric acid in an insoluble form. In all cases (except one, in which there is an unexplained discrepancy) there is a decrease in the total phosphoric acid after germination, which is due partly to the action of the steeping water in removing some of the soluble phosphates, whilst a further portion is removed by the rootlets of the young barley plant.

With regard to the determination of the acidity of malt, the author condemns the use of litmus as altogether unreliable, whilst he advocates the employment of methyl-orange and phenolphthalein. The last of these he recommends as a safe indicator for acid salts, whilst he employs methyl-orange for the detection of free acid; he states that acid salts such as primary phosphates are neutral, and secondary phosphates are alkaline, to methyl-orange. By the combined use of these two indicators, the author contends that he has proved that the acidity of malt is due to acid salts such as primary phosphates, and that there is no free acid in malt. Contrary to the generally accepted opinion, he also maintains that the least amount of free acid is unfavourable to the action of diastase, which, however, is not the case with the acid phosphates.—A. K. M.

Beer Wort, Nitrogenous Compounds contained in; Quantitative Separation of. H. Sehjerning. Zeits. Anal. Chem. 1896, 35, [3], 285—296. (See also this Journal, 1894, 1103, and 1895, 763.)

IN this paper the author describes the preparation of the precipitants, the relationship of the different precipitates to one another, and some improvements which the continuation of the work has led to. Four precipitants are made use of, and by means of these the author professes to be able to determine the quantities of albumin, denuclein, propeptone, and peptone.

1. Stannous chloride solution is prepared by dissolving 50 grms. of tin in an excess of concentrated hydrochloric acid, with the addition of a little platinum chloride; the solution is evaporated to about 130 grms., diluted to 1 litre, and filtered.

2. An approximately 10 per cent. solution of lead acetate is made by dissolving the normal salt in boiling water, filtering, and adding 10—12 drops of acetic acid to the litre.

3. Dilute acetic acid containing 15 c.c. of acid (45 per cent.) in the litre.

4. A saturated (about 10 per cent.) solution of uranium acetate.

Albumin is estimated by mixing about 5 c.c. of No. 1 solution with 25 c.c. of wort; the mixture is allowed to stand for 4—6 hours, the precipitate filtered off, washed with cold water, and the nitrogen determined by Kjeldahl's method.

Denuclein is precipitated together with the albumin, when about 6 c.c. of No. 2 solution are added to 25 c.c. of wort or beer and the mixture heated to boiling. Owing to the partial solubility of the precipitate, a correction has to be applied in this case equal to 0.15 c.c. of 1/10 normal acid for every 100 c.c. of filtrate and wash liquor. The denuclein = Pb — Sn.

Propeptone.—40 c.c. of No. 3 solution are diluted with 100 c.c. of water, and 0.8 gm. of ferric acetate added; the solution is heated to boiling, 20 c.c. of the wort or beer added, the mixture again boiled, and the precipitate at once filtered off and washed. The precipitate (Fe) contains also the albumin and denuclein, and the propeptone is consequently represented by Fe — Pb.

Peptone.—A mixture of 25 c.c. of wort or beer with 20—25 c.c. of No. 4 solution is heated to boiling, and then set aside in a dark place until the following day; the precipitate is then filtered off and washed with a cold 1—2 per cent. solution of uranium acetate. A correction is applied equal to 0.1 c.c. of 1/10 normal acid for every

100 c.c. of filtrate and wash liquor. The peptone is = $1r - Fe$.

A better method than that given above for the estimation of the propeptone is the following:—Five drops of acetic acid (45 per cent.) are added to 20 c.c. of wort or beer, which are then heated to about 36°; 18–20 grms. of pure powdered magnesium sulphate are added, and when this has dissolved, the mixture is allowed to stand for from a half to one hour at the ordinary temperature; the precipitate is finally washed with a cold saturated solution of magnesium sulphate containing 4–5 grms. of acetic acid (45 per cent.) to the litre. The precipitate contains the albumin and the propeptone.—A. K. M.

Milk, Determination of Lactose in, by Double Dilution and Polarisation. H. W. Wiley and E. E. Ewell. J. Amer. Chem. Soc. 1896, **18**, [5], 428–433.

In Wiley's original method, an arbitrary correction is applied for the volume of the coagulum (not separated before making up to the "mark") in the clarified milk. This correction it is now sought to determine in each individual case.

Process.—Two portions of milk, each of 65.82 grms. (with this quantity, diluted to 100 c.c., and using a Schmidt and Haensch polarimeter, each unit of rotation in 100-mm. tube corresponds to 1 per cent. of lactose), are separately treated, each with 10 c.c. of mercuric nitrate solution, diluted, the one portion to 100 c.c., the other to 200 c.c., filtered bright, and their respective rotations (a and b) observed at about 20° C. The corrected rotation (a^1) corresponding to a , when allowance is made for the volume of the coagulum, is found by the equation—

$$a^1 = \frac{ab}{a-b}$$

Similarly the volume (x) of the precipitate by—

$$x = \frac{100(a-2b)}{a-b}$$

The mercury solution is prepared by dissolving the metal in twice its weight of nitric acid (sp. gr. 1.42), and diluting with 5 volumes of water.—H. T. P.

Fat in Milk and other Articles, Improvements in Apparatus for Determining Volumetrically the Amount of. A. W. Stokes, London. Eng. Pat. 12,184, June 24, 1895.

The apparatus consists of a glass tube open at both ends, the top end being fitted with a rubber stopper and the other with a screw cap. The tube has two bulbs at its upper end, and is so marked that the exact quantities of reagents and milk may be introduced without using any measures. The lower part of the tube below the bulbs, is so graduated that every division may represent 0.1 per cent. of fat.

Amylic alcohol is first poured in up to the lower mark, then sulphuric acid to the second mark, and then milk to the top mark. After thoroughly shaking, the tube is put for an hour in water at 150°–180° F., the screw end being turned vertically uppermost. The fatty layer may then be read off. The separation of the fat is much accelerated by whirling the tube in a centrifugal apparatus. By removing the stoppers and rinsing with hot water, the tube may be readily cleaned.—L. de K.

Gluten in Meal, Determination of. M. Bolland. Comptes rend. 1896, **123**, [2], 136.

DIFFERENT samples of meal, having the same percentage of nitrogen, give different amounts of gluten according to their quality and method of grinding. This is due to the varying amounts of bran present, which cause loss of gluten in the ordinary process for its determination. A gluten estimation is thus not sufficient to fix the content in nitrogenous matters, or the nutritive value of a meal.

—A. C. W.

Honey, Examination of. E. Beckmann. Zeits. Anal. Chem. 1896, **35**, [3], 263–284.

Detection of "Starch Syrup" and Commercial Dextrin.—The sample is dissolved in water, methyl alcohol added, and the precipitate tested with iodine. Honey gives no colour reaction with iodine, whilst the above adulterants give an

intense red to violet coloration. The method proposed by Haenen, of dialysing a solution of honey, is condemned by the author, who finds that starch dextrin passes through the membrane, although more slowly than the natural dextrin of honey; there are also differences in their behaviour with yeast, the dextrin of honey being most readily attacked.

Detection of Commercial Glucose in honey depends upon the presence of dextrin in the former. For the qualitative test, 5 c.c. of a 20 per cent. solution of honey are mixed with 3 c.c. of a 2 per cent. solution of barium hydrate, and 17 c.c. of methyl alcohol are added. If the honey be pure, the solution will remain bright after agitation, but if adulterated with starch dextrin or glucose, a distinct precipitate will be formed. For a quantitative test, a more concentrated solution of the honey (up to 50 per cent.) is used, the precipitate being collected in a Gooch crucible and weighed. An addition of cane sugar to honey is not easy to detect with certainty, since it forms a normal constituent, and, according to different authorities, the maximum amount is placed at from 5 to 16 per cent.

Detection of Molasses.—This substance is characterised by the precipitate it gives with basic lead acetate and methyl alcohol. The solution to be tested should not, however, contain more than 25 per cent. of honey. The precipitate is attributed partly to the raffinose present in molasses.—A. K. M.

Quinazol and Diaphtherine. J. Pharm. Chim. 1896, **3**, [10], 495.

See under XVIII. C., page 609.

"Cresochline." J. Pharm. Chim. 1896, **3**, [10], 497.

Caffeine, Determination of. Georges. Journal de Pharm. et de Chim. **4**, [2], 58–59.

THE substance containing caffeine is mixed with fine sand and the caffeine completely extracted by an aqueous solution of sodium salicylate. The solution and washings are concentrated on the water-bath, and the caffeine dissolved out by chloroform; on evaporation pure caffeine remains, and can be weighed.—J. T. D.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Magnesium Nitride, Some Reactions of. O. Emmerling. Ber. **29**, [11], 1635.

ALTHOUGH readily attacked by water, this compound is indifferent towards a number of reagents, alcohol and ethyl iodide having no action, even at 200° C. in sealed tubes. The anhydrides of organic acids, however, appear to react readily upon it, though acid chlorides are inert. If acetic anhydride be added to the pulverised nitride, heat is evolved, and the product yields, on fractional distillation, 15 per cent. of acetonitrile. In the case of benzoic anhydride, heat is also developed, accompanied by an odour of oil of bitter almonds, and up to 42 per cent. of benzonitrile. The acids of these anhydrides are, however, entirely without action.—C. S.

Rhodium, Iridium, and Palladium, Solubility of Carbon in. H. Moissan. Comptes rend. 1896, **123**, 16.

THESE metals, like platinum, dissolve carbon at the temperature of the electric furnace, but do not unite with it, the whole of the carbon being separated as graphite on cooling.

—A. C. W.

Nitro-Disulphonic Acid, Deep Blue. P. Sabatier. Comptes rend. **122**, [25], 1479–1482.

THE author has succeeded in preparing this acid synthetically, by acting on dilute sulphuric acid (the commercial acid plus one-fifth or one-sixth of its volume of water) saturated with sulphur dioxide and cooled to 0° C. with a mixture of equal volumes of nitrogen trioxide and air. After a short time, nitric acid is evolved and the liquid turns a deep violet-blue. The resulting acid solution gradually decomposes, but is more stable than the potassium salt obtained by Fremy and Raschig, being able to resist a temperature of 100° C. for half an hour.—C. S.

COMMERCIAL ORGANIC ANALYSIS: A Treatise on the Properties, Proximate Analytical Examination, and Modes of Assaying the Various Organic Chemicals and Products employed in the Arts, Manufactures, Medicine, &c., with Concise Methods for the Detection and Determination of their Impurities, Adulterations, and Products of Decomposition. By ALFRED H. ALLEN. Second Edition, Revised and Enlarged. Volume III.—Part III. Vegetable Alkaloids (concluded), Non-basic Vegetable Bitter Principles, Animal Bases, Animal Acids, Cyanogen and its Derivatives. J. and A. Churchill, 7, Great Marlborough Street, London. 1896. Price 16s.

THIS, though nominally Part III. of Vol. III., is practically Vol. V. of Allen's Commercial Organic Analysis. It contains preface, table of contents, and text covering 497 pages. An alphabetical index is added.

The work treats of the following subjects:—**VEGETABLE ALKALOIDS.** Alkaloid of Papaya, Alkaloids of Colchicum, Laburnum and Furze, Stavesacre, Celabar Bean, Gelsemium, Ipecacuanha, Pomegranate, Jaborandi, Pepper, Sabadilla, the Hellebores, Potato, and Aconite. **NON-BASIC VEGETABLE BITTER PRINCIPLES.** Glucosides of Conifers; of Willow and Poplar; of Mustard, Saponins. Glucosides of Digitalis; of Strophanthus; of Jalap and Scammony. Nonglucosidal Bitter Principles. Aloes, Bitters, or Aloins. Artemisia Bitters. Colocynth Bitters. Bitters of Cocculus Indicus. Bitters and Resins of Hops. **ANIMAL BASES.** Diamines. Amides. Betaines. Urea and Analogues. Imido Bases. Xanthine or Alloxan Bases. Ptomaines. **ANIMAL ACIDS.** Acids of Urine. Hippuric Acid. Glycuronic Acid. Acids of Bile. Lactic Acids. **CYANOGEN AND ITS DERIVATIVES.** Simple Cyanides. Double Cyanides. Cyanates. Thiocyanates. The text of the work is illustrated with 25 woodcut illustrations.

Trade Report.

TARIFF CHANGES AND CUSTOMS REGULATIONS.

(From the Board of Trade Journal.)

FRANCE.

Tariff Decisions.

The following decisions recently given by the French Customs have been received at the Board of Trade:—

Lard, mixed with oil, with or without the addition of tallow, cannot be classed under "alimentary fats" (*graisses*

alimentaires), it not being made up to present the outward appearance of butter. "Bromotorm" and "Santonine" are no longer to be classed amongst chemical products in the manufacture of which alcohol has been used. Santonine will be classed under the second paragraph of Art. 282; and bromotorm will pay the same duty as bromine.

ITALY.

Tariff Classification.

According to a Ministerial Notice published in the *Bollettino di Notizie Commerciali*, "Mildiol," for tariff purposes is assimilated to "Creoline," and is to pay duty under "Drugs, not denominated (non-alcoholic)," according to No. 69 of the Customs tariff.

EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

ARTICLES OF INTEREST TO TECHNOLOGISTS.

FOREIGNERS IN GERMAN TECHNICAL SCHOOLS.

U.S. Consular Reports, July 1896, 588.

Consul Doederlein, of Leipsic, transmits the following to the Department:—It is a well-known fact that the technical schools in Saxony are celebrated throughout the world for their excellence, and it is also well known that it is almost impossible for foreigners to gain admittance, especially to those of the textile branch. The following clipping from the *Leipziger Tageblatt* shows the animus of Saxon exporters and manufacturers. It runs thus:—

"The fact that many foreigners are received into the technical schools of Saxony, and that the knowledge acquired thereat is subsequently used in order to create undertakings abroad which are intended to compete with our Saxon industry, has induced a number of our textile manufacturers in Limbach to represent to the Saxon Government the desirability of not permitting foreigners to attend the technical schools. The Government has not complied with this wish, but rather replied in the sense that the standpoint is a too narrow-minded one, and that the competition existing abroad has arisen less through students of the technical schools than through the large number of volunteers who have been accepted in Saxon business firms. It is by the admission of such volunteers that the manufacturers themselves train up their own subsequent competitors."

GERMAN EXPORTS TO THE UNITED STATES.

U.S. Consular Reports, June 1896, 225.

The exports of Germany to the United States during the quarter ending March 1896, so far as the northern consulates only are concerned, and exclusive of Dresden and Zittau, show a decided increase over the exports from the same consulates during the like period of 1895.

At Berlin, paper were nearly doubled (37,259·21 dols., against 67,064·73 dols. this year), and gloves and glove leather jumped from 60,932·18 dols. to 159,963·84 dols., while sheep guts and rennets increased from 37,494·21 dols. to 124,810·55 dols. Chromos and photographs also doubled in export values, from 20,361·18 dols. to 40,061·97 dols.

Hamburg's large increase (457,551·59 dols.) is due almost exclusively to beet sugar, 716,493 dols. worth having been exported this year, against only 38,981 dols. in the corresponding quarter of 1895. The same causes—reduction of the great stores of sugar in the United States and the war in Cuba—produced like effects as regards Magdeburg, a great beet-sugar region, whence sugar to the value of 1,148,409 dols. was exported, as against 121,990 dols. last year. At Hamburg, as at Magdeburg, chemicals have increased. At Magdeburg, as at Stettin, Portland cement shows a large increase. At Hamburg, notable decreases are seen in coffee (56,304 dols.), rags (11,344 dols.), crude india-rubber (44,326 dols.), india-rubber manufactures (23,818 dols.), and raw hides (122,083 dols.).

Magdeburg shows an increase in muriate of potash and kainite.

Stettin repeats Hamburg's and Magdeburg's increase in raw beet sugar (855,631 dols.), and has slight increases in seeds, hemp, and ozoerite.

At Bremen, the large increase in raw-sugar export (144,000 dols.) has not been enough to overcome a decrease in other articles of export.

Brunswick's export of raw sugar fell to one-half what it was last year; refined sugars increased, however, about 36,000 dols. The export of chemicals was about tripled, that of animals doubled, and that of muriate of potash increased to about five times the amount of last year's first quarter.

At Breslau, a great increase is to be noted in leather gloves (1,215,850 dols.), and smaller in porcelain and china (17,467 dols.) and chemicals (5,138 dols.).

The falling off at Chemnitz (121,462 dols.) is chiefly in cotton hosiery (338,883 dols.), silk gloves (81,320 dols.), and woollen hosiery (23,029 dols.).

Hanover's decrease of 102,552·36 dols. is pretty evenly distributed, the largest falling off being in cement, which is 40,593 dols. behind last year's quarter, and paper stock, decrease 23,394 dols.

Finally, Leipzig is to be noted with a decrease of 66,388·69 dols., for part of which a falling off of about 30,000 dols. in beet sugar is responsible, while increases are to be seen in leather gloves (25,000 dols.), essential oils (2,000 dols.), and china (6,000 dols.).

Twelve southern consulates of Germany (Frankfort and consulates thereunder) show likewise an advance in value of exports in the first quarter of this year as compared with the first quarter of 1895, but not so large an advance in proportion to the total export as in the 13 northern consulates.

The total exports to the United States from the northern consulates, including Dresden and Zittau, amounted in the first quarter of 1896 to 3,211,997·36 dols., and in the first quarter of 1895 to 2,142,847·61 dols., showing an increase of 772,149·72 dols.

The fact that 26 consulates of Germany show about 1,000,000 dols. more in exports for the first three months this year than they did during the same period in 1895, is remarkable when the almost steady falling off of the annual exports from all Germany to the United States in the past down to the beginning of 1895 is considered: In 1890, 98,800,000 dols.; 1891, 97,300,000 dols.; 1892, 82,900,000 dols.; 1893, 96,200,000 dols.; 1894, 69,100,000 dols.

SCHEDULE OF IMPORT DUTIES LEVIABLE IN BRITISH CENTRAL AFRICA.

U.S. Consular Reports, July 1896, 527.

(1.) A duty of 5 per cent. *ad valorem* on all goods except guns, gunpowder, and ammunition (which are subject to a duty of 10 per cent.), and machinery, agricultural implements, and materials for making railways, tramways, or roads, materials to be used as coffee manures (as defined below), vehicles, and live stock, which are allowed to be imported free of duty.

The substances defined as coffee manures, which are allowed to be imported free of duty, are the following:—Sulphate of ammonia, sulphate of potash, nitrate of soda, nitrate of potash (saltpetre), carbonate of potash, guano, dissolved guanos, fish guanos, fray beutos guano, sombrero, bone-ash, dissolved bones, burnt bones, raw and bruised bones, phosphatic manures (embracing the different forms in which this mineral may be obtained as a marketable commodity, such as superphosphates), coprolites, gypsum, dried blood, horn dust, shoddy, ponaac, sulphuric acid, insecticides, with appliances for using the same.

(2.) A duty of 10 per cent. *ad valorem* on guns, gunpowder, and ammunition.

(3.) The following duties on alcohol or liquids containing alcohol:—On wine, ale, porter, and beer of every sort, per case of 1 dozen old wine bottles or part thereof, 5 per cent. *ad valorem*; on brandy, whisky, rum, gin liquors, and miscellaneous spirits or strong waters not being sweetened or mixed with any article so that the degree of strength cannot be ascertained by Sikes's hydrometer, where the degree of strength does not exceed proof, for each Imperial gallon or part thereof, 12s., and for every degree or part of a degree overproof, an additional duty, per Imperial gallon or part thereof, of 1s.; on brandy, whisky, gin, rum, and miscellaneous spirits or strong waters, these being sweetened or so mixed that the degree of strength cannot be ascertained, per each Imperial gallon or part thereof, 12s.

REPORT OF COMMITTEE ON FOOD PRODUCTS ADULTERATION.

(*Eyre and Spottiswoode, 1896. Price 9d.*)

The report of the Select Committee appointed to inquire into the working of the Margarine Act, 1887, and the Sale of Food and Drugs Act, 1875, and any Acts amending the same, has recently been issued. The Committee, of which Mr. T. W. Russell, M.P., was the chairman, was originally appointed in the year 1894, and met on 31 occasions, examining 68 witnesses, among whom were witnesses on behalf of the following interests:—Provisions, butter, margarine, cheese, lard, cocoa, coffee, spices, groceries, drugs, and analysts. They find that where the Acts have been well administered they have been most beneficial, but that very considerable differences exist throughout the country as to the efficiency with which local authorities exercise the powers conferred on them. The Committee are strongly of opinion that a local authority which includes even a considerable minority of tradesmen, and which has been found persistently to neglect the enforcement of the Adulteration Acts, should in this matter be superseded by some other authority. Some witnesses complained that the Government laboratory is frequently too lenient, owing to the deliberate adoption of unreasonably low food standards. The Committee see no reason to believe that the standards adopted therein are below those which are capable of justification under the present law. The Committee, however, see no sufficient reason why information as to the methods adopted by the Government laboratory should not have been communicated to the public analysts without awaiting requests for information. An important recommendation is that of a scientific authority or court of reference, which should be empowered to deal with the subject of prescribing limits and standards of quality and purity of food. After dealing with the adulteration of various food products in detail, the Committee summarise their principal recommendations as follows:—

1. That in districts other than county boroughs, where the local authorities fail to put the Acts in force, the County Council should, by their own officers, take samples for the purposes of the Acts.

2. That in connection with the sale of mixed articles it should be obligatory upon the vendor to supply the purchaser with a label setting forth that the article is mixed.

3. That the statement of admixture on labels should be legibly and distinctly printed and so as not to be obscured by other printed matter, and that existing labels should be subject to the proviso mentioned in the concluding paragraph of the section of this report headed "Labelling and sale of mixed articles."

4. That, subject to the limitations indicated in the report, invoices and equivalent documents should have the force of warranties in the cases of all articles to which the Sale of Food and Drugs Act apply.

5. That the Commissioners of Customs be authorised to examine and take samples of all food imports at the port of entry with a view to subsequent action, as indicated in the body of the report.

6. That dealers who obtain supplies of foods from abroad should be required to submit to the Customs guarantees of purity given by the foreign vendor, together with evidence that they have taken measures to see that the goods are such as they are guaranteed to be.

7. That retailers should be empowered to refuse to sell an article otherwise than in a manufacturer's unopened labelled tin or packet.

8. That the powers of section 3 of the Sale of Food and Drugs Act Amendment Act, 1879, as to the taking of samples of milk in transit, should be extended to other articles.

9. That the *maximum* penalty for refusal to sell a sample to the authorised officer be increased.

10. That the division of the sample after purchase and delivery of a portion to the vendor should be compulsory.

11. That samples should be divided into four instead of three parts, and that one of these parts should be at the disposal of the wholesale dealer.

12. That the provisions of section 5 of the Margarine Act, 1887, as to the exemption of an employer from penalty in certain cases, and punishment of an assistant, should be extended to offences under the Sale of Food and Drugs Acts.

13. That it should be obligatory upon the magistrates or court to refer articles to the Government laboratory for analysis when such course is desired by either of the parties to the case.

14. That a defendant who proposes to rely upon the warranty defence should be required to intimate this to the prosecutor within a reasonable time of the service of the summons.

15. That the time allowed for appeal to quarter sessions from decisions of local justices should be extended from three to fourteen days.

16. That any person guilty of a second offence under the Sale of Food and Drugs Acts should be liable to a *minimum* penalty of 5*l.*, and that in respect of the third or subsequent offences under those Acts and the Margarine Act, 1887, the punishment of imprisonment without the option of a fine may be inflicted at the discretion of the magistrates or court.

17. That magistrates should be authorised to make orders, at their discretion, requiring a person convicted of offences under the Acts to publish a notification of his conviction in the public press of the locality where the offence occurred.

18. That the definition of the word "food" as used in the Acts should be amended so as to include expressly all articles intended to enter into or be used in the preparation or flavouring of food.

19. That an authority should be constituted who should act as a court of reference upon scientific and other questions arising under the Acts, and who should be empowered, at their discretion, to prescribe standards and limits of the quality and purity of food.

20. That candidates for appointment as public analysts should be required to produce evidence that they possess the requisite knowledge of analytical chemistry, in the shape of a diploma or certificate given in respect of such knowledge by a recognised school of chemistry or scientific examining body, and that in the case of candidates other than duly registered medical practitioners specific tests of the requisite knowledge of microscopy and the bearing of adulterations upon health should be prescribed.

21. That the remuneration proposed to be given to a public analyst should be subject to the approval of the central authority.

22. That the artificial colouring of margarine to resemble or imitate butter be prohibited.

23. That the mixing for sale of margarine and butter be prohibited.

REPORT OF THE DANGEROUS TRADES COMMITTEE.

(London: Eyre and Spottiswoode. Price 3½*d.*)

There has recently been issued an interim report of the Departmental Committee appointed by the Home Office to inquire into, and report upon, certain miscellaneous dangerous trades. The Committee consists of Mr. H. J. Tennant, M.P., Miss May Abraham (now Mrs. H. J. Tennant), Her Majesty's Superintending Inspector of Factories; Mr. Thomas Oliver, M.D., physician to the Royal Infirmary, Newcastle-on-Tyne; and Captain Hamilton Smith, an inspector of factories, who has acted as secretary. The Committee was directed to inquire into the conditions of work as they affect the health of the operatives in the following industries and processes:—India-rubber works; paper staining, colouring and enamel; dry cleaning; basic slag works and manufacture of silicate cotton; electric generating works; sole stitching by American machinery; glass polishing; file cutting; bronzing and metallachrome powder in lithographic works; flour mills; the use of converters in metal works; the use of steam locomotives in factories; licking of labels for reels in thread mills; the use of inflammable paints in shipbuilding yards; galvanised iron works; the process of dyeing with arsenate of soda; the manufacture and use of grindstone and emery wheels; the use of lead in various forms in print and dye works; the filling of bottles by compressed air; the bottling of aerated waters; the manufacture of salt; "ending and mending" in velvet works.

The interim report deals only with the following:—Bronzing in lithographic works; paper staining, colouring, and enamelling; use of steam locomotives in factories; india-rubber works; use of inflammable paints; dry cleaning; and aerated waters.

In pursuit of their inquiry the Committee have examined 153 persons and visited 134 works. Connected with the industries upon which they now issue their report, 103 witnesses have been examined. The Committee mention circumstances which have added difficulty to their labours and made the present report necessarily incomplete. For example, "in their visit to Middlesbrough . . . after they had left that district the reference of the Committee was extended to salt works, of which there are several examples on a large scale in this neighbourhood. The time at the disposal of the Committee has not admitted of their visiting Wales, without which they do not feel they would be justified in making a report upon the use of converters in metal works. The Committee wish it to be understood that, although they believe the trades with which they now deal to be chiefly in need of regulation, their choice has necessarily been governed by the circumstances described above; they are therefore unable to report on other trades which may be equally in need of regulation, but respecting which their inquiries are incomplete."

As regards the use of locomotives in factories and the use of inflammable paints, the Committee is uncertain "within what limits the special rules can be legally applied." With reference to electricity, again—Is the Home Secretary allowed by the Factory Acts to exercise his authority over electric generating works, or is he not, and where does the Board of Trade come in? Electricity extends its operations daily, and there are many accidents which attend its use and application. Towards embracing these within the protecting arm of the State the Committee make this suggestion: they would have the words "factory or workshop" reckoned as including any sort of "premises, area, or occupations" indoors or out of doors in which the work of men's hands is employed for purposes of gain, included "in any amending or consolidating Factory Bill."

The Committee appear to have been at great pains to consider the interests of manufacturers. They have paid attention to the state of the labour market in each several industry, and to the amount and influence of foreign competition, and so far as they could they have in every way endeavoured to consider the employer, while bent on the protection of the labourer.

After a statement of general principle the report passes into details. An account is given of the conditions of labour in all the occupations enumerated above.

THE GLASS INDUSTRY OF GERMANY.

U.S. Consular Reports, June 1896, 222.

The glass industry of Germany is divided into two branches, one branch making glass by melting silicic acids with alkali salts, lime, &c., the other making articles from the glass made by the first method. Both branches employ 50,000 workers in 312 factories, of which 187 are in Prussia, 54 in Bavaria, and 68 in the other states of the Empire. Coming down to details, 207 factories make bottles and hollow ware; 76 make table glass, with a yearly production of 1,250,000 sq. m.; 18 make crystal and half-crystal glass, 28 make mirrors, 47 make pressed glass, and 3 make optical goods. To these may be added 163 factories, employing 9,000 hands, helping, in one way and another, in the further manufacture of glass or glassware. This makes a total of 475 factories, distributed as follows:—Prussia, 211; Bavaria, 108; Saxony, 33; Saxe-Meiningen, 17; Saxe-Weimar, 11; Württemberg and Schwarzburg-Rudolstadt, 10 each; Brunswick, 8; Baden, 7; Alsace-Lorraine and Saxe-Coburg-Gotha, 6 each; Schwarzburg-Sondershausen, 5; the free cities, 4; Schaumburg-Lippe, 4; Oldenburg, 3; and Mecklenburg, 2.

Competition at home and abroad is so close that no efforts can be spared to keep what has been won by hard work. Recent tariff legislation in Belgium takes that country from Germany and gives it to France.

The import of uncut glass into Germany has increased during the last three years, Great Britain and Belgium sending the largest quantities. In 1893, there came 32,275 double centners,* and in 1895, 51,299 double centners, an increase of 58.9 per cent. There were increased imports in other kinds of glass, viz., in small plates and glass pearls (from Italy and Austria chiefly); also, in hollow green glass, in which France took the lead; in raw glass and enamelling and glazing materials, these coming mostly from Great Britain.

Of glass plates, pearls, &c., 7,995 double centners were imported in 1893, 12,253 double centners in 1894, and 11,206 double centners in 1895. During the same year, raw glass and enamelling and glazing materials were imported to the extent of 6,630, 9,514, and 10,825 double centners respectively.

The export figures are very much in the Empire's favour, as shown by the following table:—

Year.	Common Green Hollow Glass.	Simple White Glass.	Table and Decorated Glass.	Mirror Glass, Uncut.
	Double Cent.	Double Cent.	Double Cent.	Double Cent.
1885	53,569	13,248	3,638	2,700
1886	59,569	13,248	3,638	2,700
1887	59,888	14,771	3,696	2,958
1888	62,180	16,299	3,809	3,125
1889	46,663	13,790	3,523	2,858
1890	55,270	11,424	4,657	3,001
1891	57,270	17,493	3,482	3,315
1892	65,152	17,553	3,439	3,572
1893	76,578	20,663	2,791	3,496
1894	79,100	19,611	3,204	3,982
1895	83,496	25,422	3,262	4,688

Here we have an increase in 10 years of nearly 100 per cent. in white glass, 58.6 per cent. in common hollow green glass, and 59.1 per cent. in cut, table, and mirror glass.

AUER-WELSBACH PATENTS AND MONAZITE IN GERMANY.†

U.S. Consular Reports, June 1896, 242.

The long-pending litigation over the German patents covering what is known as the Auer von Welsbach incandescent gas-burner terminated on the 7th November last in a decision by the German Patent Office which had the outward appearance of a substantial victory for the patentee, but which has led to a situation in this country so anomalous as to claim the interest of not only makers of

incandescent gas burners in other countries, but of producers of monazite, thorite, and other minerals, from which the thorium and other rare oxides used in such manufacture are derived.

The German patents of Dr. Carl Auer von Welsbach, the Viennese inventor of the incandescent gas-burner which bears his name, are four in number, viz.:—The original patent, No. 39,162, of September 23, 1885, and three additional or subsidiary patents, No. 41,945, of April 29, 1886; No. 44,016, of January 20, 1887; and No. 74,745, of August 15, 1891, all of which will, of course, expire with the lapse of the original patent on the 22nd of September 1900.

The enormous profits reaped by the *Deutsche Gasglühlicht Gesellschaft*, at Berlin, which controls the Auer patents in Germany, have started up a swarm of competitors, who have put on the market burners of similar construction at prices which forced the Berlin company several months ago to reduce its retail price from 15s. to 10s. per burner. The Berlin company thereupon began suit against these rival makers for infringement of the Auer patents, and, pending the decision, published warnings against the makers and users of the infringing gas-burners.

The decision is to the effect that the scope of claim 3 in the original patent (which describes the construction of the incandescent mantle, which forms the essential feature of the invention) is restricted so as to cover only the combinations of rare earths which are definitely specified in claims 1 and 3 of the same instrument; and, further, claim 3 of the additional patent No. 41,945 is cancelled altogether. Now, claim 1 of the original patent specifies certain combinations of oxides for the impregnation of mantles, which render a gas flame incandescent and produce therefrom a white, yellow, or greenish light. The substances named in this clause are magnesia and the oxides of lanthanum, yttrium, and zirconium for white light, to which is added "neodymium" to produce a yellow light, and erbium to give the flame a greenish tinge. Neither in clause 1 nor in clause 3 of the original patent is there any mention of thorium oxide (thoria), which, as is well known, forms the principal material in all modern incandescent mantles, the proportion of thorium ranging in some formulae as high as 98 or even 99 per cent., the remaining ingredient being an oxide of cerium, yttrium, erbium, or zirconium, to modify the colour of the light produced.

This importance of thorium seems to have been realised by Dr. Auer only after long experiment, and its use for the purpose named was covered by claim 3 of his supplemental patent (No. 41,945), of April 29, 1886. But in the recent trials it has been shown that the use of thorium for this purpose was not original with Dr. Auer, and that clause of his patent is therefore annulled, leaving the use of pure thorium open and free to everyone in Germany. But, as is generally known, pure thorium produces under such conditions a greenish, ghastly light of no industrial value. In order to give out the white and yellow shades of incandescent light required for ordinary use, it must be combined, as above stated, with other oxides of the cerium-erbium group. Experts declare that the exact formula by which the Welsbach mantles of the Berlin Gasglühlicht Gesellschaft are actually made is not described or even mentioned in any of the Auer patents, and, as the use of thorium for this purpose is free, they rely upon the fact that thorium, when derived from monazite, usually contains small percentages of cerium and erbium oxides, and may therefore be used directly, in its natural condition, for the manufacture of incandescent mantles. As a natural combination of chemical elements cannot be patented, it would be very difficult to prove whether the combination of thorium and other oxides used by a rival manufacturer were natural or artificially composed. So confident are many experts of their ability to evade the existing patents that there are now in the field not less than 12 manufacturers of gas-burners more or less similar in type to the Auer. Of these rival makers, seven, including the Meteor Gaslight Continental Company, are located at Berlin, and there are others at Dresden, Munich, Karlsruhe, and other German cities.

These makers, undismayed by the decision of November 7, have pushed the competition vigorously, and to the

* 1 double centner = 220.46 lb.

† See also this Journal, 1895, 405, 610, 835.

great temporary advantage of the public. The Auer Company, at Berlin, was forced to again reduce its price to 5s. per burner, while the Meteor Company furnishes burners of apparently identical brilliancy and permanence for 5s. each, and at these rates the use of incandescent gas-burners is becoming all but universal in Germany. Further litigation is certain to follow, but the power of the original monopoly is apparently broken, and its former exorbitant prices can probably never be re-established.

The Market for Monazite.

From the American standpoint, one of the most interesting results of this controversy is its influence upon the current demand for monazite. According to Professor Nitze, assistant State geologist of North Carolina, the product of monazite sand in the Carolinas was 65 tons in 1893, 300 tons in 1894, and about 600 tons in 1896, and as such sand, containing from 60 to 75 per cent. of monazite, is worth in Germany from 25*l.* to 27*l.* per ton, the subject is one of definite commercial importance. Thus far, the European market has been largely dominated by the supply of monazite sand from Brazil, where it is found in the form of a fine, washed seashore sand, containing usually only from 2 to 3 per cent. of thorium, whereas the Carolina monazite abounds in crystals of all sizes up to that of a grain of wheat, and contains generally from 3 to 6 per cent. of thorium. But for the reason that the Brazilian sand is uniformly fine, free from particles of titaniferous iron, and can be put directly into the extracting process, without being artificially pulverised, it is preferred by the Auer-Welsbach companies at Vienna and Berlin. The North American monazite, on the other hand, must first be ground to a fine powder, which, in consequence of the hardness of the crystals, is a somewhat tedious process, unless the best machinery is employed. For these reasons, and owing to the fact that large consignments of Brazilian monazite sand have been recently received at Hamburg, the market is now somewhat congested, and the prices offered no longer tempt exporters in the United States. A ton of Brazilian monazite sand, costing at present in Hamburg 2*4* *l.* 15*s.*, yields, when well worked out, from 20 to 25 kilos, of pure thorium, which is worth from 500*l.* to 625*l.*, according to degree of purity.

The whole situation confirms the suggestion already made in these reports, that the ultimate and effective plan of organising the monazite industry in our country would be to establish there, at a convenient point in the mining district, a laboratory, where, by employing the most improved and economical methods, the monazite—including the poorer sands which have been concentrated by a process recently perfected—may be worked up, the thorium extracted, and made available as a finished product in all countries where incandescent gas-burners are manufactured.

Thorium oxide is now worth in Germany from 25*l.* to 31*l.* per kilo., according to purity, and the demand is thus far greater than the supply. Most manufacturers of incandescent burners would prefer to buy their supply of thorium ready for use than to conduct a separate laboratory for extracting and preparing it.

The one pertinent question, from an economic standpoint, would be whether the chemicals which are used in extracting thorium can be transported from New York or Baltimore to the Carolina monazite district more cheaply than the crude sand can be brought from there to Europe, where from 96 to 98 per cent. of its bulk becomes at the first operation absolute waste material. The chemicals required for this process are neither rare nor costly, and with a well-chosen site, at which water power may be utilised for pulverising the raw material, the success of such an enterprise would, in the opinion of competent authorities, be practically assured.

MINERAL AND METAL TRADE OF SPAIN.

U.S. Consular Reports, July 1896, 590.

Under date of April 18, 1896, Consul-General Bowen, of Barcelona, transmits the following statistics covering the exports and imports from and to Spain of minerals and metals during the year 1895:—

Exports of Minerals.

Description.	Quantity.	Value.
	Tons.	Dols.
Iron	5,179,761	7,586,600
Copper	501,408	3,183,000
Zinc	29,346	244,500
Lead	9,206	635,800
Manganese	29,507	235,000
Antimony	9	500
Common salt	251,232	635,500
Pit coal	8,318	33,200
Pyrites	488,699	814,500
Total	6,503,943	13,852,100
Total in 1894	11,204,000

Exports of Metals.

Description.	Quantity.	Value.
	Tons.	Dols.
Iron	22,660	265,300
Copper	59,507	3,642,000
Zinc	1,367	105,500
Lead	151,429	7,043,300
Quicksilver	1,240,000
Gold	94,600
Silver	6,965,000
Total	13,343,700
Total in 1894	13,200,000

Imports of Minerals and Metals.

Description.	Quantity.	Value.
	Tons.	Dols.
Pit coal	1,515,504	6,825,000
Coke	255,043	1,148,000
Tar	33,766	563,000
Petroleum, crude	43,992	1,009,500
Iron	38,336	1,650,000
Tinned iron plate	1,241	86,800
Tin ingots	825	346,000
Gold	100,000
Silver	4,000,000
Alkaline carbonates	27,591	1,046,000
Nitrate of soda	26,385	1,320,000
Sulphur	6,813	1,016,000

The importations of minerals and metals into Spain during 1895 amounted to 650,000 dols. less than in 1894.

THE PRODUCTION OF CIDER IN FRANCE.

Board of Trade Journal, June 1896, 648—651.

The year 1895 has been a good one for cider manufacturers in France, the amount produced having risen to 25,586,514 hectolitres, or an increase of 11,803,785 hectolitres over the average of the last ten years. The most characteristic feature of the year is, however, not so much the total production of cider as the sale of apples, which has taken place to an enormous extent with Germany. These apples are there manufactured into cider and "German champagne," in which Germany does a large export trade, very little of the products being consumed at home. At the present time France exports on an average barely 13,000 hectolitres of cider, while Germany, which grows scarcely any apples at all of her own, exports ten times as much, and at very high prices. The cider manufacture is an important industry in the city of Frankfurt, which has five large factories and 15 of less importance, French apples being entirely used. In this connection the advantage of agricultural syndicates for production and sale is pointed out.

The country between Vimontiers and Argentan and the district around produces the best kinds of cider. The nature of the soil has, doubtless, much to do with the excellence of French ciders: the variety of apple used is also an important factor; thus:—*Acid* apples give an abundant, clear, and light juice, but the cider made from them is

liable to turn black, and is generally weak and difficult to keep. *Sweet* apples give a clear cider which is agreeable to the palate while new, but as soon as the sugar is exhausted it turns sour and acquires a bitter flavour. *Bitter* or *sour* apples give the most generous cider, which is of a fine colour and keeps well.—J. G. W.

THE ALGERIAN PHOSPHATE DISPUTE.

Chemical Trade Journal, August 15th, 1896, 98.

Sir Lambert Playfair, in his last report on Algeria, refers to the recent attacks in the French Senate and press on the English phosphate owners at Tebessa (*Chemical Trade Journal*, 145 and 147). Sir Lambert reported some time ago on a visit which he made to the phosphate quarries at Tebessa belonging to Mr. Crookston, and described the manner in which the latter had, by his intelligence and practical good sense, turned to his own profit and to the benefit of the colony a branch of industry which had been entirely discredited by the failure of those who had previously risked their capital in it. An English house had taken over a concession made to a Frenchman, M. Wétérli, near Souk Abras; he lost 48.00% in the speculation; a French firm lost even more in attempting to work the deposits in the valley of the Chélif; so when M. Chapelle discovered the deposits at Tebessa he could find none of his countrymen, either in Algeria or in France, disposed to engage in what was then considered a most risky speculation. He finally addressed himself to Mr. Crookston, of Bône; thus this gentleman became associated with the enterprise. Instead of giving Mr. Crookston the credit due to him for having so successfully developed this important industry, the press, both in Algeria and France, broke out into a fury of invective for the way in which the mineral wealth of Algeria was being squandered for the benefit of Englishmen. There was a general demand that something should be done to preserve this valuable produce for the benefit of the colony, and that export duties should be imposed on all mineral shipped by the English to foreign countries. A violent attack was made in the French Senate by M. Pauliat. "Do not forget," said he, "that the English who work these deposits make a profit of 10*l.* to 15*l.* a ton; calculate therefore an extraction of from 15,000,000 to 20,000,000 tons annually during centuries to come." The fact is, says the Consul-General, that the concession was only granted for 18 years, and that there was no possibility of Mr. Crookston extracting more than 60,000 tons per annum under the most favourable circumstances. The alleged profit of from 12*l.* to 15*l.* per ton should in reality be 1*l.* 7*s.* 0*d.* per ton. The actual cost of extraction, transport, shipping, &c., of mineral averaging 60 per cent. of phosphoric acid is 34*l.* 3*s.* 0*d.*, and the price realised, April 1895, did not exceed 36*l.* per ton for second quality. Since then the prices have fallen still further, with the result that a marked restriction in the shipments of phosphates from Bône has taken place, as only the highest quality can now be profitably worked, the lower qualities, for the present at least, being abandoned. The total production towards the close of 1895 had reached 600 tons daily, but it has now fallen to 300 tons per day, and a still further reduction is to be feared unless the Government intervenes in order to reduce the present rate of railway charge, so as to enable the exploiters to compete on more favourable conditions with the American mines than they do at present. Of the three companies actually engaged in phosphate mining in the Tebessa district, the Société Française had completely suspended operations, the Constantine Company of Leith has reduced its output to 100 tons per diem, while the Crookston have reduced their production to 200 tons. As the last firm hold very large stocks of phosphate at Bône, a still further reduction of their output is contemplated. "Thus it is seen to what insignificant proportions this enormous natural treasure is now reduced, and how exaggerated have been the expectations regarding it. It cannot be doubted that this industry, once so promising, has been shrivelled up, mainly owing to the political campaign that was directed against it, and to the subsequent action and interference of the State, which, one would think, had the greatest interest in seeing it develop and flourish. It is a proof of what

requires no proof, of the wisdom of leaving unfettered well-directed private enterprise, and of the advisability of the State only intervening to foster and encourage it."

GENERAL TRADE NOTES.

SUGAR IN SPAIN.

Chamber of Commerce Journal, July 1896, 125.

Only a few years ago Spain was dependent upon other countries for a part of the sugar she consumed beyond that produced at home and in her colonies. France supplied refined, and Germany, Holland, and England manufactured sugars. According to a *Bulletin* of the French Chamber of Commerce at Barcelona, the position is now changed, and with the aid of her colonies, Spain is able to satisfy her own requirements. The same authority states that the sugar industry has existed in Spain from time immemorial; the cultivation of the sugar-cane on the shores of the Mediterranean, in the valleys between the provinces of Malaga and Almeria, has always been one of the sources of well-being of those parts, and the sole agricultural wealth which has favoured them in a constant manner. There were, at one time, about 29 cane-sugar factories in the Peñinsula; the number is now reduced to about 19, in consequence of the inherent vicissitudes of this class of undertakings; they are situated in the two provinces of Malaga and Almeria. In spite of the disappearance of some of the factories, the *Bulletin* believes that the production of cane-sugar has not at all diminished, owing to the extension of the plant of those factories which have survived their difficulties, and whilst it would be difficult to establish exactly the production of the existing factories, it is estimated that their output exceeds 15,000 tons per annum. A new impetus has also been given to the industry by beetroot cultivation. Fifteen years ago MM. Crens and Rubio, of Grenada, undertook the first experiments in the fertile neighbourhood of that town; these did not give much encouragement at the outset, but led to the hope that by judicious selection of seed, and the diffusion among the growers of knowledge of the means of cultivation likely to produce the best saccharine yield, that they could create an industry as important and as flourishing as in other countries. They therefore installed a factory of modest proportions, and obtained at the end of a few years some satisfactory results. This attracted capital to the industry, and in a short time 11 factories were founded in the district, all of them more imposing than the pioneer. There are now said to be 20 factories in Spain exclusively concerned with beetroot, and their output is estimated to exceed 20,000 tons per annum, or larger than that of the older cane-sugar industry. In addition to the cane and beetroot factories there have been founded also four refineries (two of them very old establishments), which treat raw Colonial sugar; the home production goes into consumption as it leaves the producing factories.

TANNING IN UNITED STATES.

Chamber of Commerce Journal, July 1896, 125.

The statements we give below will, we doubt not, appear somewhat startling, but they appear in the *Moniteur Officiel du Commerce* as received from a correspondent at New York. The correspondent says: "I have been able, in the course of my travels in the west and centre of the United States of America, to see for myself the progress made in the great industries of the country, in tanning particularly. The large industrial companies of the United States concerned with the production of leather annually import about ten million cow and ox hides from the island of Madagascar. Commercial relations between the States and Madagascar are so well founded with their agents, and the coasting trade so cheap, that all the large industrial companies obtain these hides at less than 20 centimes per kilo, delivered here (U.S.A.). In manufacturing terms, the hides, after having been soaked and cleaned by various chemical processes, are introduced into vats containing the first tanning liquor. This tanning operation is generally performed here by divers mechanical processes, with or without the application of electricity. The tanning is completed by an increase

of the tannic strength (*degré tannique*), according to the thickness of the hides, from—and commencing at—1 up to 20°. The average cost price of a Madagascar cow or ox hide weighing 18 kilos. (as a minimum) delivered at a United States port is 3 frs. This hide, being generally tanned in 120 days, yields about 60 per cent. or 10 kilos. 80 of leather, and its tanning has cost about 2 frs. 50. Such leather sells on the American market, or for export, at the rate of 1 fr. 75 per kilo. According to this rough estimate an average hide of 18 kilos. costs up to the point of conversion into leather 5 frs. 50, and consequently such a hide, yielding 60 per cent. or 10 kilos. 80 of leather, gives a profit of 13 frs. 40 per hide, or 134,000,000 frs. profit that the United States tanners obtain from this industry to the detriment of the French tanning industry. It is necessary to remark that the figures above given are absolutely short of the truth, and that this one commercial branch secures to the United States tanners rather 150 than 134 million francs."

THE GERMAN CHEMICAL INDUSTRY.

Chemist and Druggist, August 15th, 1896, 278.

The chemical factory "Harburg" at Stassfurt report that the sale of their principal article of manufacture—*viz.*, refined saltpetre—has declined by about 5 per cent. during their last business year, as compared with the year 1894-95. Since July 1895, the factory has entirely stopped the manufacture of refined camphor, because the price of the raw material was forced up to a figure at which the refined article left no profit. Owing to the Spanish-German tariff war, the exports of the factory to Spain fell from 222 tons in 1894 to 122 tons in 1895. The chemical works "Buckau," in Magdeburg, are about to lay down plant at their Stassfurt works for the manufacture of ammonia salts. Many other German potash factories are also taking up the manufacture of new articles. This applies particularly to the manufacture of caustic potash for soapmakers' use, for which several new plants have been put down. Up to the present, caustic potash is made chiefly by the chemical works at Griesheim, their branch factory at Bitterfeld, and the electro-chemical factory, also at Bitterfeld. All these works appear to make a considerable profit out of the article, small quantities of which (all of excellent quality) are also made by the United Chemical Factory at Leopoldshall. All of this, however, is at present used by the factory for its own consumption, but the commercial production of the article will be discussed at the next general meeting. The Leopoldshall works have recently purchased the prussiate and cyanide of potash factory of Schachnow and Wolff, and they are also considering the erection of a special factory for chromate of potash.

COAL DISCOVERED IN ONTARIO.

Engineering and Mining Journal, July 18th, 1896, 53.

A most important discovery has lately been made in the Sudbury district. It is well known that lignite coal exists around James Bay, coming down in one place to within 200 miles of the main line of the Canadian Pacific Railway. But no one had ever imagined that coal would be found to the south of the "Height of Land," that forms the backbone of Northern Ontario from the Ottawa River to Lake of the Woods, and especially as Sir William Logan had declared over 40 years ago that there was "no coal in Upper Canada," as the Province of Ontario was then called. Of course at that time little or nothing was known of these great northern regions, except along the shores of the Georgian Bay and Lake Superior. Even after the building of the Canadian Pacific Railway, and until the publication of Mr. Bell's map of the nickel belt in 1892, the rocks of the Sudbury district were supposed to be too old for the existence of coal in any of them, being mostly of Laurentian and Huronian origin. But in the trough between the two main nickel ranges there is one oblong area of Cambrian formation, consisting of dark-coloured sandstones and black slates about 10 miles wide and some 40 miles in length, extending in a north-easterly direction from the township of Trill almost to Lake Wahnapiatae. In this Cambrian strip, a few

miles south of the railway and 15 miles west of Sudbury, a prospector looking for gold has discovered a bed of fine anthracite coal, very clean, compact, and said to be equal in quality to the best Pennsylvania hard coal. The extent of the deposit has not been ascertained yet, but the outcrop is over 20 ft. in width, and a number of men are at work stripping along the strike of the ledge. There is every probability that other coal beds occur in the same locality, and though the matter has been kept very quiet, several parties have already gone out to explore around there. It is quite possible that coking coal may be found farther to north, and in that event the Sudbury district would become one of the great mining and industrial centres of the world. In any case, if this coal deposit is of permanent depth and equal in quality to the surface samples, it will prove of immense benefit to Ontario, which now has to import all the coal used in the province.

CALCIUM CARBIDE.

Electrician, August 21st, 1896, 531.

We learn that the Acetylene Illuminating Company have concluded arrangements with the British Aluminium Company, by which they will be able to erect works of several thousand horse-power for the manufacture of calcium carbide—using water-power. Pending the construction of such works, the Acetylene Company have obtained the use of a considerable portion of the spare water-power of the existing works of the British Aluminium Company at Foyers, and a carbide plant is now being erected there, which, it is expected, will be in full work during the month of October next.

- 16,306. W. Oliphant. Improvements in apparatus for drying solid materials. July 23.
- 16,352. R. H. F. Finlay. Improved evaporating apparatus. July 27.
- 16,355. W. McG. Greaves. Improvements in appliances for the prevention of smoke from furnaces. July 27.
- 16,659. J. Foster. Improvements in and relating to apparatus for condensing steam vapour or gases, applicable also as a feed-water heater. July 28.
- 17,053. J. Foster. Improvements in and relating to evaporating apparatus. Aug. 1.
- 17,105. F. D. Cummer. Improved means applicable for use in the separation and collection of solid matters held in suspension in aeriform fluids. Aug. 1.
- 17,279. G. St. John Mildmay. Improvements in or connected with means for charging vessels with liquefied or compressed gases. Aug. 5.
- 17,365. D. J. Morgan. Improvements in furnace fire-bars and the manufacture of same without patterns. Aug. 6.
- 17,408. H. Hirzel and R. Hoffmann. Improvements in apparatus for mixing and roasting materials of approximately equal specific gravity, and for separating materials of different specific gravity. Complete Specification. Aug. 6.
- 17,428. A. C. Halse. Improvements in apparatus for the generation of gases. Aug. 7.
- 17,530. G. Helps. Improvements in and relating to regenerative furnaces for heating gas retorts and the like. Aug. 8.
- 17,532. T. Nicholson. Improvements relative to the heating of boilers, kilns, and flues, and furnaces generally, by radiation instead of direct firing. Aug. 8.
- 17,546. J. Liddle.—From W. Hardie. Improved method of separating or extracting the oil from and filtering the feed water for steam boilers and apparatus connected therewith. Aug. 8.
- 17,559. W. McG. Greaves. Improvements in furnaces. Aug. 8.
- 17,821. T. B. Booth and A. Robinson. Improvements in apparatus for carbonating liquids. Complete Specification. Aug. 11.
- 17,862. C. A. Künzel, jun. Improvements in filters. Aug. 12.
- 17,980. W. L. Wise.—From Solvay and Co. Improvements in decanting apparatus. Aug. 13.
- 18,137. J. L. Dobell. Improvements in means or apparatus for condensing nitrous acid or other fumes or vapour. Aug. 15.

COMPLETE SPECIFICATIONS ACCEPTED.*

1895.

- 15,103. E. A. Pellet. Manufacture of refractory substance and apparatus therefor. Aug. 12.
- 15,565. F. W. Saatzmann. Drying and absorbing apparatus. Aug. 5.
- 16,693. W. J. Lomax and C. J. Lomax. Filtration of liquids. Aug. 12.
- 17,742. S. Cutler. Safety fittings for water-gas generators. July 29.
- 18,218. J. Foster. Evaporators. July 29.
- 19,103. A. M. Hugill, J. Overton, and R. H. Catley. Apparatus for heating, evaporating, and concentrating infusions and liquids. Aug. 19.

1896.

2543. H. H. Lake.—From A. S. Nichols. Improvements in drying kilns, and in the method of operating the same. July 29.
7251. L. M. G. Delannay-Belleville. Distilling apparatus for the production of fresh or drinking water. Aug. 5.
9560. A. H. Wethey. Calcining furnaces. Aug. 12.
- 13,386. F. Grumbacher. Improved aeration and fermentation apparatus for yeast, indigo, and the like. Aug. 5.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

- 15,987. T. F. May. Improvements to aid combustion in grates, furnaces, &c., to simplify and economise construction, to economise fuel, lessen smoke, and destroy germs. July 20.
- 16,003. J. Patison, sen. Improvements in utilising smoke peat or peat bog by neutralising the organic acids therein. July 20.
- 16,027. A. W. Knotts. An improved process in connection with illuminating gases. July 20.
- 16,157. N. B. Taylor and J. C. Dias. Improvements in coke ovens. July 21.
- 16,244. M. H. Hawes and P. Cannell-Bunn. Improvements in the manufacture of mantles for gas and other burners. July 22.
- 16,277. L. V. Prati and P. Marengo. Improvements in the production of pure hydrogen gas and the application of hydrogen to the obtaining of light, heat, and power. July 22.
- 16,345. R. Haddan.—From A. Boter. Apparatus for production of acetylene gas. Complete Specification. July 23.
- 16,425. G. Shenton and D. A. F. de Villepigue. Improvements in means for vaporising and burning liquid fuel. Complete Specification. July 24.
- 16,432. A. Schmidt. Improvements in the production and purification of acetylene gas and in apparatus therefor, also in and connected with portable lighting apparatus for burning such gas. July 24.
- 16,443. O. Imray.—From C. V. Potter. An improved method of and means for increasing heat production and more perfect combustion in furnaces. July 24.
- 16,541. M. Ekenberg. Improvements in the manufacture of solidified petroleum. Complete Specification. July 25.
- 16,692. W. L. Wise.—From E. Thomson. Improvements in the manufacture of gas and apparatus therefor. July 28.
- 16,728. A. J. Boulton.—From F. Alexandre. Improvements in the production of acetylene gas, and in the means or apparatus employed therein. Complete Specification. July 28.
- 16,735. S. Marcus. Improvements in burners for gasifying and burning hydrocarbons, chiefly designed for the production of light by incandescence. Complete Specification. July 28.

16,843. R. P. Pietet. Improvements in the purification of acetylene and in apparatus therefor. Complete Specification. July 29.

16,844. R. P. Pietet. Improvements in the manufacture of acetylene and in apparatus therefor. Complete Specification. July 29.

16,847. P. Woog. Improvements in and relating to acetylene generators and lamps. July 29.

16,966. W. Nicholls. Improvements in the manufacture of incandescence bodies for illuminating purposes. July 30.

16,984. H. Strache. An improved method or process of and apparatus for removing gaseous iron compounds from water-gas. July 31.

17,038. L. T. FitzGibbon. Improvements in and connected with apparatus for generating and storing acetylene gas. July 31.

17,066. T. Birnbaum. Improvements in means or apparatus for burning illuminating gas. Aug. 1.

17,134. G. Allemann and La Maison Frères Stemmer. Improvements in automatic apparatus for generating and storing acetylene gas, and for utilising the same for illuminating and other purposes. Aug. 1.

17,194. W. L. Voelker. Improvements in materials for incandescing mantles and processes for manufacturing the same. Complete Specification. Aug. 4.

17,198. B. Grau. Improvements in cooking ovens. Aug. 4.

17,209. G. C. Fowler and M. B. Fowler. Improvements in the manufacture of night lights. Aug. 4.

17,228. A. Verley. Improvements in apparatus for the production of ozone. Aug. 4.

17,450. W. C. Clarke. Apparatus for generating acetylene gas. Complete Specification. Aug. 7.

17,514. H. C. B. Forester. Improvements in or relating to the manufacture of artificial fuel. Aug. 7.

17,596. W. P. Thompson. — From W. Buddens. An improved incandescent body or mantle for incandescent gas light. Aug. 8.

17,605. W. H. Wheatley. — From C. Schmid. Improvements in the manufacture of incandescence bodies for illuminating purposes. Aug. 8.

17,644. R. Goodwin. A gas plant and system to make and produce acetylene gas, or acetylene and carbonic acid gas combined. Aug. 10.

17,646. M. Duffield. An improved acetylene gas generator. Aug. 10.

17,678. A. C. Fraser. Improvements in process and apparatus for generating and liquefying acetylene. Filed Aug. 10. Date applied for Feb. 21, 1896, being date of application in United States.

17,714. A. J. B. Lege and A. D. Pennellier. Improvements in the production and burning of acetylene gas. Aug. 11.

17,729. I. N. Knapp. Improvements in the treatment of illuminating gas. Complete Specification. Aug. 11.

17,778. B. T. L. Thomson. Improved means for producing carbonic acid and hydrogen gases. Aug. 11.

17,904. H. H. Lake. — From O. Grenier and J. Grand. Improvements in and relating to apparatus for generating and utilising acetylene gas for lighting purposes. Aug. 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

15,366. T. G. McEwen. Manufacture of gas. Aug. 19.

16,272. A. Perlich. Lamp for the production of spirit gas incandescent light with lighting and extinguishing contrivance. July 29.

17,568. O. Rose. Method of producing peat charcoal and apparatus therefor. July 29.

17,742. S. Cutler. See Class I.

18,248. C. J. Fox. Apparatus for projecting liquid fuel intimately mixed with air and steam in a state to be burnt for heating steam boilers and for other purposes. Aug. 5.

18,334. F. Livezey. Apparatus for the extraction of cyanides and other compounds from illuminating and other gases. Aug. 5.

18,877. P. Dvorkovitz. Means or apparatus for distilling, applicable also for enriching gases by means of hydrocarbons. Aug. 19.

1896.

5051. R. G. Shadbolt and J. Wilson. Means for enriching coal-gas. Aug. 19.

7477. P. Schroedter. Incandescence gas burners. Aug. 5.

10,568. V. I. Feeny. — From P. Carmien, A. Yvonne, and M. Billon. Automatic gas-producing apparatus and burner therefor. July 29.

11,707. E. F. J. C. Bauweraerts. Burner for acetylene gas. Aug. 12.

11,708. E. F. J. C. Bauweraerts. Apparatus for the generation of acetylene gas. Aug. 5.

14,929. A. H. J. Schultke. New or improved apparatus for the production and combustion of acetylene for illuminating purposes. Aug. 19.

15,167. M. Meyer. Incandescent light burners. Aug. 12.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

15,992. P. W. H. Gray. Improvements in the manufacture of inks. July 20.

16,039. J. J. M. Ville. New red colouring matters—rodazines—of the triphenylmethane group, and method of producing the same. July 20.

16,449. K. Vidal. Improvements in colouring matters. July 24.

16,582. T. R. Shillito. — From J. R. Geigy and Co. Improvements in the production of azo colours. July 27.

17,064. I. Levinstein and Levinstein, Lim. Production or manufacture of new colouring matters. Aug. 1.

17,065. I. Levinstein and Levinstein, Lim. Manufacture or production of new colouring matters. Aug. 1.

17,168. A. Bang. — From G. A. Dahl. New dyestuffs and the production of the same. Aug. 4.

17,207. O. Imray. — From G. H. Weiss. Manufacture of amino-oxy-carbanilic acid and azo dyestuffs therefrom fixed on chrome mordants. Aug. 4.

17,226. E. H. Temple. Improved ink. Aug. 4.

17,293. M. Lange. Process for the manufacture of intermediate compounds containing two diazo groups. Complete Specification. Aug. 5.

17,382. C. Uffelmann. Manufacture of a solid paste or soap compound for dyeing all kinds of textile materials. Aug. 6.

17,444. M. Ward and I. Ward. Improvements in the manufacture of liquid blue for laundry use. Aug. 7.

17,590. S. Pitt. — From L. Cassella and Co. Improvements in the manufacture of primary disazo dyestuffs. Aug. 8.

17,591. H. E. Newton. — From The Farbenfabriken vormals F. Bayer and Co. The production of dyestuffs on fibre. Aug. 8.

18,020. W. H. Claus, A. Rée, and L. Marchlewski. Production of new azo dyes. Aug. 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

14,276. G. W. Johnson. — From F. von Heyden Nachfolger. A process for the manufacture of aromatic nitrosulpho-chlorides. July 29.

17,639. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Manufacture of new diamido bases derivatives of azimidobenzene and of azo dyes from these. Aug. 5.

17,660. B. Willeox.—From The Badische Anilin und Soda Fabrik. The manufacture and production of new mordant-dyeing colouring matters. July 29.

71,738. H. E. Newton.—From The Farbwerke vormals F. Bayer and Co. The manufacture or production of dye-stuffs for cotton. July 29.

19,253. H. H. Lake.—From The Farb. Mulheim. Manufacture of sulpho acids of the naphthalene series, and of colouring matters derived therefrom. Aug. 19.

20,530. H. H. Lake.—From K. Ochler. Manufacture of colouring matters. Aug. 12.

20,548. I. Levinstein and Levinstein, Lim. Manufacture of a sulpho acid which may be employed in the production of colouring matters. Aug. 5.

1896.

12,743. H. Imray.—From F. Petersen. Manufacture of substantive cotton dyestuffs from benzidine sulpho acids. July 29.

13,744. O. Imray.—From The Society of Chemical Industry in Basle. Manufacture of new disazo, trisazo, and polyazo colouring matters. July 29.

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATIONS.

16,336. H. K. Tompkins. Improvements in the manufacture of artificial silk. July 23.

16,570. T. Illingworth. Improvements in the means or method of rendering wool fibres and yarns spun from wool unshrinkable. July 27.

16,578. J. E. L. Barnes.—From W. Wall. Improvements in machinery for treating cotton seed. July 27.

16,840. E. Edwards.—From F. A. Bernhardt. Improvements in the process of what is known as "Mercerizing" fabrics composed of vegetable fibres. July 29.

17,841. W. Grimshaw. Improvements in and in means for ornamenting textile and other fabrics or materials. Aug. 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

16,143. S. W. Wilkinson and The Grove Co., Lim. An improved method of and apparatus for removing tar, pitch, oil, grease, and similar matter from wool, fur, and the like. Aug. 5.

17,028. A. Hitchon. Apparatus for breaking up or opening cotton and other textile materials. Aug. 19.

18,765. H. H. Lake.—From A. K. J. von Gerkan and E. Zietz. Process of producing floor-covering material and the like from the needles or leaves of pine trees. Aug. 12.

23,942. W. P. Thompson.—From E. Clavier. Process for the manufacture of yarn or thread from paper, and apparatus therefor. Aug. 12.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

16,786. J. Lees and H. Arnold. Improvements in bleaching apparatus. July 29.

17,157. R. Pickup. Coloured resists, with aniline black. Aug. 4.

17,692. C. Dratz. Process and apparatus for printing multicoloured designs upon fabrics and warp chains. Aug. 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

19,444. R. Michel. Producing print patterns in colours on cotton fabrics by the aid of safranine-azo dyestuffs. Aug. 19.

1896.

3991. H. H. Lake.—From J. C. Blundell. Yarn-dyeing machines. Aug. 12.

12,500. H. Schirp. Improvements in dyeing, washing, and rinsing apparatus for textile goods. July 29.

13,191. E. Heberlein. Process and apparatus for the production of colours with silk-like gloss on vegetable fibres and textile fabrics; also on wool, india-rubber, leather, wood, metal, and other substances. July 29.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

15,999. T. Parker. Improvements in the manufacture of certain salts of sodium and potassium. July 20.

16,128. C. H. Simpson and F. H. T. Allan. See Class XII.

16,146. J. A. Wanklyn and W. J. Cooper. An improvement in the manufacture of cyanides. July 21.

16,255. L. M. Bullier. Improvements in the manufacture of carbides of the earth-metals and alkali-earth metals. Filed July 22. Date applied for Dec. 28, 1895, being date of application in France.

16,877. D. Bray. A still or tank for the distillation, boiling, and holding of acids, alkali, and other corrosive liquids. July 30.

16,944. H. Kunheim. An improved process for the manufacture of liquid chlorine, and apparatus therefor. July 30.

17,009. J. B. Kasten. A mode or process of making nitrates. July 31.

17,055. W. Mills. Improvements in preparing ammoniac silicofluoride. Aug. 1.

17,127. J. C. Graham. An improved process for the preparation and purification of solutions of copper. Aug. 1.

17,243. V. Beanquet. Improvements in the manufacture of alkaline cyanides. Aug. 4.

17,488. A. Kumpfmüller and E. Schultgen. Improvements in and connected with evaporation and concentration of solutions of salts. Complete Specification. Aug. 7.

17,607. J. R. Wyld, J. W. Kynaston, and J. Brock. Improvements in the manufacture of hydrochloric acid free from arsenic. Aug. 8.

17,839. H. Brewer. See Class X.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

9052. J. C. Butterfield. See Class X.

1896.

7002. H. H. Lake. From L. Sternberg. Production of ammonia from waste products, such as the waste lyes resulting from the extraction of sugar or the manufacture of alcohol from molasses. Aug. 19.

VIII.—GLASS, POTTERY, AND ENAMELS.

APPLICATIONS.

17,008. A. Simmons. Improvements in ornamenting or decorating glass, earthenware, metal, and other plates and sheets. July 31.

17,193. J. Kotzur. A novel grooved cement tile. Aug. 4.

17,278. R. Thomson. An improved joint for connecting taps to stone bottles, glass bottles, and the like; also manufacturing stone bottles and glass bottles on improved principles. Aug. 5.

17,390. P. T. Sievert. Process and apparatus for the manufacture of glass sheets, glass tubes, and cylinders for the production of glass sheets and other articles. Complete Specification. Aug. 6.

17,391. P. T. Sievert. Improvements in the manufacture of sheets, cylinders, and other forms of glass. Aug. 6.

17,599. H. Sturm. Improvements in continuous ceramic furnaces with heated movable soles. Aug. 8.

17,871. J. R. Gilman. Improvements in the process of transferring designs to china or earthenware, and an improved manufacture of transfer sheets for the purpose. Aug. 12.

COMPLETE SPECIFICATION ACCEPTED.

1896.

13,676. J. B. Vernay. Machines for manufacturing bottles and other articles of glass. Aug. 5.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

16,258. A. Gibbs and Eastwood and Co., Lim. Improvements in the burning of bricks and other material, and in apparatus therefor. Complete Specification. July 22.

16,307. W. Millar. The utilisation of a waste product in the manufacture of a hydraulic cement, cement mortar, or the like. July 23.

16,310. W. Millar. The utilisation of a waste product in the production of a wall, ceiling, or other plaster. July 23.

16,436. J. Leuba. Improvements in paving blocks. Complete Specification. July 24.

16,525. E. Selberg. New or improved building and insulating material. Complete Specification. July 25.

16,892. T. R. Jones. An improved process for hardening stone. July 30.

17,281. M. Bernstein. Improved process for producing artificial veined coloured marble. Complete Specification. Aug. 5.

17,627. W. Millar and O. J. Owen. Improvements in the composition and manufacture of artificial stone and slate. Aug. 10.

17,636. G. Hutchinson, T. H. Lawson, and A. J. Lawson. An improved compound for use as paving. Aug. 10.

17,799. E. T. Dumble. See Class XII.

17,830. J. Foster. Improvements in the construction of kilns for burning limestone, cement, and other similar material. Complete Specification. Aug. 12.

18,026. F. M. David. An improvement in the construction of fireproof partitioning for buildings. Aug. 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

16,962. A. Patriek. Manufacture of finely-pulverised substances for use in the production of Portland cement, pigments, and the like. Aug. 5.

18,109. G. de Bruyn. Fireproof ceilings. Aug. 12.

18,576. G. de Bruyn. Slabs for building and like purposes. Aug. 12.

20,246. Count A. de Sainte-Marie and A. Hoffmann. Treatment of wood. Aug. 5.

1896.

9838. J. Wilkinson. New or improved manufacture of compositions suitable for use as building materials for architectural and other purposes. Aug. 12.

12,169. A. J. Boulton.—From M. Thys. Manufacture of artificial stone. Aug. 12.

13,649. R. F. Strong. A new or improved process for the treatment of peat and other ligneous substances for producing paving blocks, slabs, tiles, slates, conduits, and fuel. July 29.

X.—METALLURGY, MINING, ETC.

APPLICATIONS.

16,032. W. H. Hyatt. Improvements in apparatus for separating gold from other materials. July 20.

16,085. J. Bigwood and T. C. Bigwood. Certain improvements in machinery for galvanising or otherwise coating metal sheets with metals or alloys. July 21.

16,180. J. B. Torres. Improvements in and connected with the manufacturing and refining of iron, steel, and their alloys. July 22.

16,312. A. M. Clark.—From E. A. Ashcroft. Improvements in the treatment of solutions of ores containing zinc for the recovery of zinc as oxide. July 23.

16,372. W. R. Renshaw. Improved means for and method of cleansing and detinning waste tin plates, old manufactured plates, such as biscuit tins and the like, and depositing tin and other metals in conjunction. July 24.

16,419. P. M. Justice.—From J. H. King. Improvements in the extraction of metals from their ores. July 24.

16,485. D. Colville, jun. Improvements in the manufacture of composite armour plates. July 25.

16,603. C. F. W. A. Focke. Improvements in processes for cleaning iron and steel. July 27.

16,604. F. Ellershausen. Improvement in the treatment of complex sulphide ores. July 27.

16,685. C. Vautin. An improved method for the production of metals and alloys. July 28.

16,698. F. W. Golby.—From M. Liebig and The Aetien Gesellschaft für Zink Industrie, vormals W. Grillo. A new or improved process for separating zinc and analogous metals from their sulphur compounds. July 28.

16,756. Elkington and Co., Lim., and H. T. Fellows. Improvements in muffles for annealing metals and for other like purposes. July 28.

16,820. W. Huselton and N. Moore. Improvements in ore concentrators. July 29.

16,831. W. T. Sugg. Improved metallic alloy. July 29.

17,074. T. Andrews. Improvements in apparatus for consolidating metallic scrap. Complete Specification. Aug. 1.

17,076. L. Albrecht. Improvements in tin-plate furnaces. Complete Specification. Aug. 1.

17,299. E. F. Turner. An improved process for the treatment of zinciferous ores. Aug. 5.

17,372. L. H. Goodman. Improvements in furnaces for the disintegration of quartz and other minerals. Aug. 6.

17,474. J. Williams, sen. Improvements in the method of and means for reducing lead scum or litharge. Aug. 7.

17,493. C. W. H. Göpner and H. L. Diehl. Improvements in the recovery of gold and silver from their solutions. Aug. 7.

17,551. E. F. Goodyear, G. W. Goodyear, and T. Kennelly. Improvements in appliances to be used in connection with brazing hearths, and other apparatus employed in the heating and fusion of metals. Aug. 8.

17,593. I. A. Timmis. Improvements in cupolas and blast furnaces. Aug. 8.

17,601. E. Edwards.—From H. Wachwitz. An improved process for coating aluminium with other metals. Aug. 8.

17,623. A. Phillips. An improved form of metal purifier. Aug. 10.

17,680. W. P. Thompson.—From T. G. Orwig. New or improved hard metal or alloy, and process of manufacturing the same. Aug. 10.

17,839. H. Brewer. Improvements in and relating to the treatment of zinc ores or ore residues in the production of zinc chloride, sodium sulphate, and other products. Aug. 12.

17,864. L. R. Scammell. Improvements in the treatment of sulphide ores. Aug. 12. Date applied for July 13, 1896, being date of application in Australia.

17,941. B. Thomas and J. W. Thomas. Improvements in connection with the elimination of arsenic from metallic copper. Aug. 13.

18,006. J. Swinburne. Improvements in coating metals with aluminium and its alloys. Aug. 11.

18,013. R. Thomson. Improvements in treating ores of precious metals and in apparatus therefor. Aug. 14.

18,081. C. P. Sherck, J. L. Rutter, and S. Weiss. An improved process and means for converting pig iron into malleable iron or steel. Complete Specification. Aug. 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

9052. J. C. Butterfield. Treatment of blue stone and other sulphurised ores. Aug. 12.

15,141. A. Shedlock. Apparatus for separating and concentrating ores and other materials in the pulverised or granular state. Aug. 5.

17,618. W. T. Leyshon. Additions to machinery for coating metals. July 29.

17,901. W. J. May. Ferro-sodium fluxes. Aug. 12.

17,932. Davies Bros. and Co., Lim., E. A. Davies, and S. T. Thomas. Preparing metal sheets for the purpose of galvanising them or otherwise coating them with metal or metallic alloy. Aug. 19.

21,575. H. Partin. A new alloy of aluminium. July 29.

1896.

13,187. B. Kleber. Process for the manufacture of weather-proof gypsum, stone, or bricks. Aug. 5.

11,479. A. F. Cothias. Manufacture of metallic alloys. Aug. 5.

14,957. C. James. An improved process for the reduction of argentiferous and auriferous copper ores, mattes, or compounds without loss of the copper, silver, or gold. Aug. 19.

15,159. C. James. Process for the extraction of copper from sulphuretted ores or compounds. Aug. 19.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

16,057. C. Kellner. Improvements in electrolytic apparatus. July 20.

16,091. A. Stevens and F. Puttaert. Improvement in electric batteries. July 21.

16,256. L. M. Bullier. Improvements in electric furnaces. July 22. Date applied for Dec. 28, 1895, being date of application in France.

16,257. L. M. Bullier. Improvements in electric furnaces. Filed July 22. Date applied for Jan. 27, 1896, being date of application in France. July 22.

16,268. W. Rowbotham. Improvements in electric batteries. July 22.

16,270. M. O. A. Garreau. Improvements in secondary electric batteries. July 22.

16,516. J. Vaughan-Sherrin and H. H. Sherrin. Improvements in accumulator batteries. July 25.

16,597. R. M. J. Heurtey and P. Germain. Improvements in and relating to primary batteries. July 27.

16,726. F. W. Schneider. Improvements in electrodes for secondary batteries. Complete Specification. July 28.

16,729. L. G. Attenborough and E. A. Sulman. Improvements in the manufacture of caustic soda and other alkaline hydrates and compounds by electrolysis. July 28.

16,852. G. Poore. Improvements in electrolysis. Complete Specification. July 29.

16,916. E. Strzelecky. Apparatus for obtaining oxygen and hydrogen from steam by electrolysis. July 30.

17,001. R. Pauli. Electrolytic manufacturing of cyanide of alkali. July 31.

17,161. S. Hammacher. The manufacture of an improved active material for the plates or electrodes of electric accumulators. Aug. 4.

17,346. F. F. E. Heyse and W. H. Akester. Improvements in or connected with secondary or storage batteries. Aug. 6.

17,698. The Cowper-Coles Galvanising Syndicate, Lim., and S. O. Cowper-Coles. Improvements in means or apparatus for effecting the electro-deposition of zinc or other metals upon tubes or other circular or analogous objects. Aug. 8.

17,671. L. Hoepfner. An improved method for obtaining porous metals by electrolysis. Aug. 10.

17,879. V. M. Cornely and L. C. H. Dautel. Improvements relating to electric batteries. Aug. 12.

18,016. M. M. Brophy and J. D. F. Andrews. Improvements in electric accumulators or secondary batteries. Aug. 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

15,024. E. Andreoli and G. Andreoli. Electrolytic production of amalgams, and their utilisation. Aug. 12.

16,692. A. Patrick. See Class IX.

17,505. C. Hoepfner. Electrodes. Aug. 5.

17,525. C. Kellner. Electrolytical manufacture of bleaching liquid. Aug. 19.

17,655. B. M. Drake and J. M. Gorham. Secondary batteries. July 29.

22,505. F. Dannert, H. Windolff, and J. Zacharias. Active material for electric accumulators. July 29.

XII.—FATS, OILS, AND SOAP.

APPLICATIONS.

16,128. C. H. Simpson and F. H. Tielke Allan. An improved process for making soap and caustic soda. July 21.

16,129. C. H. Simpson and F. H. T. Allan. An improved process for the purification of spent lyes. July 21.

16,746. W. F. Haywood. Improvements in process and apparatus to be used in the manufacture of soap. Complete Specification. July 28.

16,766. J. Merz. Improvements in or relating to the extraction of fats, oils, resins, sulphur colours, tanning materials, and the like by means of volatile solvents and apparatus therefor. Complete Specification. July 28.

17,118. F. U. Klever. Improvements in lubricants. Aug. 1.

17,379. C. Schmidt. Improvements in processes for producing chemical combinations from raw wool fat. Complete Specification. Aug. 6.

17,446. E. Weldon. Improved harness soap. Aug. 7.

17,548. J. H. Hunter. An improvement in the process or method of purifying and separating butter, fatty, oily, or other substances. Aug. 8.

17,815. J. E. T. Woods and H. B. McKenna. Improvements in the manufacture or conversion of certain hydrocarbon oils for the production of a fluid oil suitable as a solvent for resinous gums and for medicinal purposes. Aug. 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

18,239. J. Holmes, H. E. Tankard, and W. Sealie. A new or improved method of and apparatus for removing fatty matters from the effluent waters of wool-washing machines and the like. Aug. 5.

1896.

15,050. G. C. Dymond.—From G. F. Metzger. Separating oil from its volatile solvent. Aug. 19.

15,597. G. C. Dymond.—From G. F. Metzger. Process and apparatus for separating naphtha or other volatile solvent from oil. Aug. 19.

XIII.—PAINTS, PIGMENTS, VARNISHES, RESINS, INDIA-RUBBER, Etc.

APPLICATIONS.

16,276. A. Gutensohn. Improvements in the manufacture of oxide of lead, and means used therefor. July 22.

16,857. J. Danby. A non-conducting and protective composition specially adapted for covering the surfaces of metallic structures, but applicable also to other structures, to prevent radiation of heat. July 29.

17,031. A. M. Clark.—From W. Hampe and C. Schnabel. Improvements in the manufacture of zinc pigments. July 31.

17,078. H. W. Aird and C. E. Felch. Improvements in paint and in the method of producing and applying same. Aug. 1.

17,799. E. T. Dumble. Improvements in process for hardening bituminous substances. Complete Specification. Aug. 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

14,839. A. Pullrook. New or improved compound applicable for rendering articles waterproof or air-tight, or as a cement or varnish, or for other similar purposes. Aug. 12.

17,871. W. L. Gunn. Improvements in compositions for protecting ships' bottoms against fouling, preserving wood, and shielding submarine electric cables from penetration by torpedo worms. Aug. 5.

21,717. W. Walters and W. T. Nichols. An improved patent-leather dressing. Aug. 5.

1896.

8981. S. Ganelin. Production of a substitute for white lead and of other oxy-salts of lead from lead sulphate and lead chloride. July 29.

15,689. J. W. Steiger and P. D. McArthur. Stick sealing-wax. Aug. 19.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATIONS.

16,420. E. S. Cook. An improved process for treating raw hide for use in the construction of pneumatic tyres. July 24.

16,600. E. Avellis and E. Koster. An improved process for preparing chrome-dressed leather for dyeing purposes. Complete Specification. July 27.

16,764. J. Blunck. Improvements in the process of tanning hides, skins, or the like. Complete Specification. July 28.

17,370. E. E. E. Martens. A new or improved process for the preparation of liquid glue for joiners, upholsterers, and the like. Complete Specification. Aug. 6.

17,420. R. Widemann. A new or improved process of treating leather. Complete Specification. Aug. 6.

COMPLETE SPECIFICATION ACCEPTED.

1896.

13,281. W. L. Wise.—From Knoll and Co. Manufacture or production of an albumen-tanning compound. Aug. 12.

XV.—AGRICULTURE AND MANURES, Etc.

APPLICATIONS.

16,861. R. Tugener. Apparatus for turning faecal matter into manure and for disinfecting water-closets. July 29.

17,151. C. Fell. The natural fertiliser. Aug. 4.

17,883. E. van De Griendt. Treatment of moss-litter manure for obtaining products therefrom. Aug. 12.

XVI.—SUGARS, STARCHES, GUMS, Etc.

APPLICATIONS.

16,009. W. Field. Improvements in extracting sugar from molasses by means of barium hydroxy-sulphide and recovering the same from the resulting by-products. July 20.

16,065. A. Glaser. Improvements in vacuum-apparatus for use in the manufacture of caramels and the like. July 20.

16,340. S. W. Wilkinson. Improvements in the manufacture of sulphocarbonates of starch, dextrin, and sugars. July 23.

16,411. W. Feld. Improvements in extracting sugar from molasses by means of barium hydroxy-sulphide and recovering the latter. July 24.

17,054. J. F. Williams. Improved method of and apparatus for boiling sugar, glucose, and jam. Aug. 1.

17,195. J. A. Link. Improvements in and relating to adhesive compounds. Complete Specification. Aug. 4.

17,536. E. J. Mills. Improvements in formation and preparation of soluble colloids of the gelatine class. Aug. 8.

18,138. C. F. Kastengren. An improved method of purifying molasses, syrup, or other solution of sugar by means of animal charcoal. Complete Specification. Aug. 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1896.

5953. C. F. Kastengren. Method of purifying molasses, syrup, or other solution of sugar. July 29.

15,485. A. Rohrbach. A new or improved process for purifying centrifugally separated substances. Aug. 19.

XVII.—BREWING, WINES, SPIRITS, Etc.

APPLICATIONS.

16,229. H. Koch. A new or improved process in or relating to the preparation of yeast. July 22.

16,663. A. Fox. The brewers' wort sample cooler. July 28.

16,671. J. Dunn. Improvements in treating barley for alimentary purposes, including brewing and distilling. July 28.

17,183. A. Lippke. Process for the preservation of beer. Complete Specification. Aug. 4.

17,246. L. Prochazka. An improved process and apparatus for mashing and brewing. Complete Specification. Aug. 4.

17,316. C. J. Gerry. See Class XVIII. A.

COMPLETE SPECIFICATION ACCEPTED.

1895.

19,171. N. Anderson. Apparatus for blending or mixing spirits. Aug. 19.

XVIII.—FOODS, SANITATION, ETC., AND DISINFECTANTS.

APPLICATIONS.

A.—Foods.

16,016. A. Backhaus. An improved treatment of the milk of cows or other domesticated animals to render it suitable as food for infants and children. July 29.

17,316. C. J. Gerry. Improvements in the treatment or preparation of tea, coffee, cocoa, sweetmeats, aerated waters, wines, spirituous liquors, or other beverages or articles of food or diet. Aug. 5.

17,611. F. Rebling. A new or improved process for producing blood-forming and nourishing means. Aug. 8.

17,658. W. Junge. Improvements relating to the preservation of beer, milk, water, meat, fruit, and other substances, and to apparatus therefor. Aug. 10.

17,720. H. M. Amos. Improvements in fruit evaporators. Aug. 11.

18,803. A. Maefadyen and R. T. Hewlett. An improved apparatus for pasteurising or sterilising milk or other fluids. Aug. 15.

B.—Sanitation.

16,034. E. W. Ives. Improvements in apparatus for the treatment of sewage and other liquids. Complete Specification. July 20.

16,078. J. Royston. An improved mode of treating night soil. July 21.

16,280. W. D. Scott-Monerieff. Improvements in or relating to the treatment of sewage and apparatus therefor. July 23.

17,526. C. H. Fitzmaurice and E. Mann. Improved means for softening water and apparatus therefor. Aug. 7.

C.—Disinfectants.

17,380. S. E. Gunion.—From J. W. Hill. Improved gases or vapours for disinfecting and for destroying germs and insects, and apparatus for producing such gases or vapours. Aug. 6.

COMPLETE SPECIFICATIONS ACCEPTED.

A.—Foods.

1895.

15,255. S. Griffin. Improvements in means for preserving food. July 29.

18,043. A. Ernecke. Apparatus for preserving food and the like. Aug. 5.

23,505. W. P. van Wyk. Manufacture or preparation of cocoa or chocolate powder. Aug. 12.

1896.

12,523. T. F. Garrett and W. M. Spouse. Consolidated soups and vegetable juices. Aug. 5.

14,196. G. C. Dymond.—From G. H. Walker, G. E. Gordon, and J. H. Waterhouse. Treatment of milk for the purpose of suiting it to individual indigestions. Aug. 5.

14,581. C. L. Bachelier. Process of preserving organic substances, more particularly applicable for elementary substances. Aug. 5.

B.—Sanitation.

1895.

16,401. J. J. Hartnett. Apparatus for disinfecting and purifying air. July 29.

18,093. B. W. Slater and The Native Guano Co., Lim. Treatment and purification of sewage and impure water. July 29.

C.—Disinfectants.

1895.

18,229. E. Burton. Disinfectant and cleansing and purifying compound. Aug. 5.

XIX.—PAPER, PASTEBOARD, ETC.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

18,503. W. Brothers. Process or treatment of waste materials obtained in the manufacture of ammonium compounds to produce a substance suitable for use as a paper filling in the manufacture of paper. July 29.

19,008. J. S. Rigby. Application and utilisation of the residual liquors produced in the manufacture of vegetable parchment paper. July 29.

1896.

7234. The British Xylonite Co., Lim., and S. W. Brooke. Manufacture of xylonite, celluloid, and similar compounds of nitro-cellulose. July 29.

9914. L. Capazza. Manufacture of stylographic paper. Aug. 5.

15,519. G. L. T. Hartmann. Apparatus for the manufacture of millboard, pasteboard, or the like. Aug. 19.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

APPLICATIONS.

16,047. J. C. Mewburn.—From The Chemische Fabrik von Heyden Gesellschaft mit beschränkter Haftung. Improvements in mono alkyl-ethers of pyrocatechin and in the production of such ethers. Complete Specification. July 20.

16,162. J. C. Mewburn.—From The Chemische Fabrik von Heyden Gesellschaft mit beschränkter Haftung. A new perfume and process for the manufacture of the same. Complete Specification. July 21.

16,239. G. B. Ellis.—From La Société Chimique des Usines du Rhone, anciennement G. P. Monnet et Cartier. Improvements in the manufacture of vanillin. July 22.

16,860. H. Higgins. Methods for causing the separation of caseinogen or casein from separated milk and its preservation in a dry state. July 29.

17,177. J. J. A. Trillat. Improvements in the production of vapours of formic aldehyde and in apparatus therefor. Filed Aug. 4. Date applied for Jan. 3, 1896, being date of application in France.

17,401. C. Fahlberg. Improvements in the manufacture of saccharine or compounds thereof, or mixtures containing the same, and in the production and treatment of materials for use therein. Complete Specification. Aug. 6.

18,035. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Improved manufacture of oxy-camphor. Aug. 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

16,762. C. D. Abel.—From The Fabriques de Produits Chimiques de Thann et de Mulhouse. Manufacture of artificial musk. July 29.

18,297. J. C. Richardson. Manufacture of artificial camphor and its treatment. Aug. 5.

24,615. M. Woolf. The preparation and production of essences or extracts from vegetables. Aug. 12.

1896.

3998. A. J. Boulton.—From G. Barthel. Process and apparatus for the preparation of aldehydes. Aug. 5.

XXI.—PHOTOGRAPHY.

APPLICATIONS.

18,036. B. Acres. Improvements in the manufacture of films for photographic purposes. Aug. 14.

18,131. J. A. Michel-Dansac and L. Chassagne. Means for reproducing the colours in photography, suitable also for dyeing and printing. Complete Specification. Aug. 15.

XXII.—EXPLOSIVES, MATCHES, Etc.

APPLICATIONS.

16,038. E. Kubin. Improvements in or relating to the manufacture of explosives. July 20.

16,858. H. Maxim. Improvements in the manufacture of pyroxylin smokeless explosives and in apparatus therefor. July 29.

16,859. H. Maxim. Improvements in nitro-compounds whereby their chemical stability is increased. July 29.

17,204. M. Bielefeldt. Process for the manufacture of explosives containing saltpetre. Complete Specification. Aug. 4.

17,307. C. E. Biebel. Improvements in the manufacture of nitro-glycerine explosives. Aug. 5.

18,034. M. Bielefeldt. Improved manufacture of explosives. Aug. 14.

18,078. B. Willecox.—From The Action Gesellschaft Dynamit Nobel. An improved explosive or blasting composition. Complete Specification. Aug. 14.

18,142. H. S. Maxim. Improvements in the manufacture of smokeless explosives. Aug. 15.

COMPLETE SPECIFICATION ACCEPTED.

1895.

17,535. P. R. J. Willis.—From W. C. Peyton. Apparatus for making gunpowder. July 29.

XXIII.—ANALYTICAL CHEMISTRY.

APPLICATION.

17,897. W. P. Thompson.—From A. Legrand. An improved testing carafe or bottle for indicating the richness in cream, of milk. Aug. 12.

PATENTS UNCLASSIFIABLE.

APPLICATION.

17,717. F. J. Jones and G. W. Jones. A chemical compound. Aug. 11.

COMPLETE SPECIFICATION ACCEPTED.

1896.

7793. C. Stahlschmidt. Manufacture of a new product from sugar, brown iron ore, and chloride of sodium. Aug. 12.

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

[Non-Members 30/- per annum; Members 21/- per Set of extra or back numbers; Single Copies (Members only) 2/6.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed. The circulation of the Journal is now more than 3,000 per month.

MONUMENT TO LAVOISIER.

For the Lavoisier Monument International Fund, set on foot two years ago by the Academy of Sciences at the instance of M. Berthelot, nearly 2,000*l.* has now been collected, and it is hoped that a worthy monument will be ready for inauguration in May 1900. Alsace has contributed about 100*l.*, Germany 160*l.*, England 130*l.*, and Austria-Hungary 100*l.* The French Minister of Public Instruction will give 240*l.*, and the city of Paris 400*l.*—*Daily News*.

I.—PLANT, APPARATUS, AND MACHINERY.

PATENTS.

Extracting Moisture from Peat and such like Materials, and Apparatus therefor, An Improved Method of. O. Rose, London. Eng. Pat. 14,533, July 31, 1895.

THE invention consists in treating the peat or other similar material in a closed chamber fitted with shafts carrying suitably-shaped blades to masticate and disintegrate it, whilst air under pressure is forced through the apparatus. The moisture is thereby forced through strainers of canvas or other suitable material into a vessel below, which may, if desired, be connected with an exhaust pump.—O. H.

Drying and Absorbing Apparatus [Swinging Plates or Shelves], Impts. in. F. W. Saatzmann, Driffield, Yorks. Eng. Pat. 15,565, Aug. 19, 1895.

THE apparatus is principally intended for drying moist sticky substances the drying of which in ordinary machines presents difficulties; but it may also be used for drying other materials, and also for absorbing gases by solid matters. It consists of a column provided with a number of horizontal shelves, each shelf being formed of a number of plates mounted on separate axes in such a manner that they can be turned separately by means of a key fitting on the exterior end of each axis, or all together by means of suitable mechanism, to allow the materials thereon to fall on to the next lower shelf. A space is left, alternately at the right- and left-hand side of each set of plates, so that the hot air or gas which enters at the bottom can pass upwards in a zig-zag manner over each shelf in succession to the outlet at the top. The material is spread over the top shelf, and is caused to descend from shelf to shelf to the outlet at the bottom by tilting the shelves in succession.—R. S.

The Production of High Vacua, Impts. in Apparatus for; [Exhausting Incandescent Electric Lamps]. A. Barr, Glasgow, and W. Stroud, Leeds. Eng. Pat. 13,188, July 9, 1895.

THE principle of the invention consists in "the combination of a rotating drum, partially submerged in mercury or other liquid, and containing passages of a somewhat spiral or helical form, which drum during its rotation effects a transference of gas from a chamber placed in communication with the vessel or vessels to be exhausted to a chamber placed in communication with a pump producing a partial vacuum, these two chambers being sealed one from the other by the liquid used in the apparatus."—O. H.

Mixing and Agitating Machinery for dealing with Liquids and the like, Impts. in. E. A. Brotherton, Leeds, and F. G. Holmes, Leeds. Eng. Pat. 16,804, Sept. 9, 1895.

THIS invention relates to the mixing of liquids, which may contain more or less solids, in a boiler, tank, or vessel of any description; and consists of arrangements whereby two opposite currents are simultaneously drawn, one from the top, the other from the bottom, churned in an intermediate chamber, and delivered through discharging arms.—R. S.

Evaporators, Impts. in and relating to. J. Foster, Pollokshields, N.B. Eng. Pat. 18,218, Sept. 30, 1895.

THIS invention relates to evaporating and concentrating vessels, especially to multiple-effect apparatus. The steam chamber is provided with two sets of vertical tubes, an outer ring of tubes of large diameter extending for about two-thirds of the circumference of the vessel, and acting as circulating tubes, and the ordinary tubes of smaller diameter connecting the top and bottom plates. The top plate is curved from the centre downwards to the sides, where it dips into a half channel or well, into which the top ends of the larger tubes open. The bottom cover of the evaporator curves downwards towards one side, leading the precipitated material to a settling pipe and pump of special form, whilst the liquid flows from the vertical tube through a branch pipe to an automatic feeding closely trapped chamber. This contains a vessel mounted on a central vertical spindle, and when it is filled to a determinate amount, the weight depresses a spiral spring, upon which it rests, and allows the liquid to flow past a valve-shaped disc. When the vessel rises, the valve is shut off again. The discharged liquid therefrom is drawn by the vacuum into the next evaporating vessel of the series.—R. S.

Evaporating Liquids [Water-Tube Principle], Generating Steam, &c.; Impts. in Apparatus for. P. C. Hewitt, New York, U.S.A. Eng. Pat. 20,126, Oct. 29, 1895.

THIS invention is to facilitate the evaporation of liquids by accelerating their circulation, and by securing a more effective contact of the liquid and heating surface by bringing more liquid in contact with such heating surface, and also by the rapid circulation of the vapour formed from the liquid. Two vertical sets of tubes are employed—highly heated ones up which the liquid passes, and one or more return tubes, which are protected so as not to be so highly heated, down which the liquid passes. At the upper end of these tubes is a special separating chamber, into which the liquid which has passed up the hot tubes discharges itself through stationary tangential nozzles, whereby a rapid rotary motion is caused in this chamber, the heavier portions of the liquid going towards the wall, passing over on inwardly projecting flange thereon, and escaping through a discharge tube. The remainder of the liquid passes down the return tube or tubes, the rotary motion thereof being arrested by wings or vanes, while the vapour escapes through a central outlet.—R. S.

Overflow Pipes of Distillation and Absorption Columns [Clearing Overflow Pipes from Incrustation], Impts. in or connected with the. H. Hirtel, Leipzig-Plagwitz, Germany. Eng. Pat. 9557, May 5, 1896.

IN order to prevent the choking or fouling of the overflow pipes of distilling and absorption columns, the patentee introduces through the vertical series of pipes, a spindle provided with scrapers to revolve or oscillate in each separate pipe. The spindle passes through a socket or projection on each plate or dish, to form a bearing, whilst an inverted cup fitted to the spindle, below the scraper, overhangs each socket to form a liquid lute or joint for the gas or vapour.—O. H.

Sulphurous Acid and other Gases or Fumes, Method of and Apparatus for Washing and Compressing. E. Porák, Kienberg, Bohemia. Eng. Pat. 12,643, June 9, 1896.

THE claim is for "A method of washing and compressing sulphurous and other gases or fumes, supplied by a sulphur burner or other gas generator, and which consists in sucking the said gases or fumes from the supply pipe by a jet apparatus adapted to force them into a liquid contained in a closed receptacle, and maintaining a continual circulation of the said liquid through the said jet apparatus and receptacle by means of a pump."—E. S.

Aërating Liquids, Improved Apparatus for, especially applicable to Fermenting Tuns and Indigo Vats. F. Grumbacher, Berlin. Eng. Pat. 13,386, June 17, 1896.

"A FERMENTATION and aëration apparatus for the manufacture of yeast, indigo, &c., characterised by the arrange-

ment of a circulation tube provided with an air-conducting tube, the upper end of which circulation tube is provided with a distributing plate and a cap, in such a manner that by the introduction of air in the air-conducting tube, air bubbles are caused in the lower part of the circulation tube and thereby a continuous circulation and aëration of the yeast or indigo fluid, is caused, for the object of bringing about a continuous intimate mixture of the same with the air."—J. L. B.

II.—FUEL, GAS, AND LIGHT.

Gas-purifying Material [Oxide], Revivification of. W. Leybold. J. f. Gasbeleuchtung, 1896, **39**, 500—502.

In the revivification of foud iron oxide it is advisable to have the oxide slightly moist, as then the revivification proceeds regularly, and there is less fear of firing than with the dry oxide. It is best to spread the material in layers about 16 to 20 ins. deep.

The author recommends the estimation of the sulphuretted hydrogen evolved when the material is treated with hydrochloric acid as the best means of determining the progress of the revivification. If a determination is made immediately after removal of the material from the purifier and this volume taken as 100, the relative volumes of sulphuretted hydrogen found in subsequent trials, represent the proportion remaining unrevivified.

The estimations can conveniently be made in the apparatus, of which a sketch is given. About 25 grms. of the oxide are quickly weighed (to 0.01 grm.) into the small glass, which is then introduced into the flask containing about 50 c.c. of commercial hydrochloric acid mixed with 50 c.c. of water. The cork is introduced into the bottle and the latter

placed in a beaker of cold water. When the temperature is pretty constant, the eudiometer is raised or lowered till the water-levels inside and out are the same, and then read off. The glass containing the oxide is then upset by slightly shaking the bottle, and when evolution of gas has ceased, the water-levels are readjusted and the gas volume again read off. Care must be taken that the oxide is thoroughly moistened with the acid, and in taking the samples these must be taken from low down in the layer of material, as on the surface the revivification takes place very rapidly.

The following is an example of many determinations:—

	1st Day.	2nd Day.	3rd Day.	4th Day.
Number of times material was turned over.	..	Twice	Twice	..
25 grms. of material yielded c.c. of sulphuretted hydrogen.	243.5	40.6	3.5	0

From samples taken from the surface no sulphuretted hydrogen was evolved after the first day. If it is not wished to follow the progress of the revivification, but merely to determine whether it is complete or nearly so, the usual Bunte burette may be employed in place of the larger one figured.

The progress of the revivification can also be determined, though less conveniently, by determining the percentage of oxygen in samples of air drawn from the centre of the mass. In the same samples as above, the following results were obtained:—

————	1st Day.	2nd Day.	3rd Day.	
Percentage of oxygen ...	0.4	0.5	4.0	
<hr/>				
————	4th Day.	5th Day.	6th Day.	7th Day.
Percentage of oxygen ...	16.0	19.6	20.0	20.4

PATENTS.

Water-Gas, Improved Process and Apparatus [Directly connected Generator and Coking Chamber] for Producing. A. J. Boulton, London. From C. Dellwik, Stockholm. Eng. Pat. 13,764, July 18, 1895.

A PROCESS for the manufacture of water-gas from bituminous coal, &c., the characteristic feature of which, is, that the generator and coking chamber are in free and direct communication with each other, and that the generator-gas is burned in a combustion chamber arranged as part of the generator, the heat produced by the combustion causing a dry distillation in the coking chamber, and the products of distillation obtained during the same period being at the same time also burned in the same combustion chamber. The combustion chamber (the upper part of which is filled with loosely piled brick or a checker-work of refractory material intended to retain or store up the heat) is above the generator, and surrounds the coking chamber. This coking chamber is wider at the bottom than the top, and is completely open at the bottom to the generator. The generator being in the first instance filled with coke, and the coking chamber with bituminous coal, the latter becomes coked, and falls into the generator as the fuel in the generator becomes used up, fresh bituminous coal being fed into the coking chamber from time to time. Thus, after the start of the apparatus, only bituminous coal is necessary.

In an alternative form of apparatus, the coking chamber is built on the slant, and the combustion chamber is placed under it.—L. T. T.

Gas, Combustible, Impts. in Apparatus for the Production of [Automatic Oil-Gas Producer]. H. Howell, London. Eng. Pat. 14,469, July 30, 1895.

This patent is for an automatic oil-gas producer. The oil-gas holder is so connected with valves in the pipes conducting the oil to the retort that as the holder fills, the supply of oil is gradually reduced, and *vice versa*.—L. T. T.

Ammonium Carbonate and Acid Ammonium Carbonate, The Manufacture of, from certain Waste or By-Products [Waste Kiln and Blast-Furnace Gases], and Apparatus for Use in such Manufacture. H. R. Lewis, London. Eng. Pat. 14,618, Aug. 1, 1895.

See under VII., page 652.

Gas from Petroleum or other Oil or the like, Impts. in and Apparatus [Vertical Retorts in Pairs] for the Manufacture of. W. Fonlis, Glasgow. Eng. Pat. 15,048, Aug. 9, 1895.

In this process two vertical retorts are used, and the oil is introduced into the first by means of a pipe with a small nozzle, which passes through the top of the retort and terminates about the middle thereof, just over a horizontal plate, so placed that the oil impinging on the said plate is sprayed and becomes vaporised without coming in contact with the hot sides of the retort. The thus partially gasified material passes into the second retort, where gasification is completed. The retorts are surrounded by heating chambers so arranged that the heating may be evenly and easily regulated and controlled.—L. T. T.

Carburetted Water-Gas [Mixture of Coal- and Water-Gas], Impts. in Apparatus for the Manufacture of. The Economical Gas Apparatus Construction Co., Ltd., London, and L. L. Merrifield, Franklin, Massachusetts, U.S.A. Eng. Pat. 15,659, Aug. 20, 1895.

This patent relates to an apparatus in which, in the manufacture of carburetted water-gas, soft or bituminous coal and Canadian, Russian, or other heavy oils can be used without wasting the coal-gas from the soft coal. The principal novelty claimed, beyond special arrangements of

valves, &c., is in the form of the generator. This consists practically of an ordinary generator A^1 with, above it and in direct and free connection with it, a retort B^2 . A^1 is filled with coke, and B^2 with soft coal. In the first blow-up, the heated gases from A^1 pass through the annular spaces S round B^2 , heating it and causing the coal-gas to be generated. This latter passes downwards into the generator and so away with the generator products. The coal in B^2 is thus coked and is ready to fall into A^1 and replace the coke originally therein as the latter is consumed. Fresh coal is fed into B^2 by the hopper Q , in small quantities, after each blow-up.—L. T. T.

Furnaces for Burning Petroleum and Hydrogen, Impts. in or relating to. A. J. Boulton, London. From C. Dusaulx, Suresnes, France. Eng. Pat. 16,713, Sept. 6, 1895.

The furnace is designed so that two concentric petroleum flames, one within the other, shall impinge upon a horizontal metal plate, which is thereby raised to incandescence, and upon which soot deposits. The heat of this combined flame, by conduction of the metal plate and by reason of the contiguity of a water receptacle, generates steam, which, in contact with the incandescent plate and the soot thereon, is decomposed into its elements. The latter instantly recombine, forming an intensely hot flame. The outer petroleum flame is fed with oil by means of a cane or rattan dipping into an oil receptacle and passing through an annular tube. The inner flame is fed from an upper and exterior oil tank by means of a tube passing upwards within the annular tube and having a regulating cock. Its upper or burner end is pointed, and is higher than the outer burner. The latter is surrounded by a truncated cone to induce a draught of air thereto. The inner flame is surrounded by an inverted truncated cone for the same reason, having side openings to allow of the entry of steam from a small annular water-chamber outside.—R. S.

Steam, or a Mixture of Steam and Air, Impts. in or relating to the Economical Production of, for Use in Gas Producers. L. Mond, Northwich, Cheshire. Eng. Pat. 16,781, Sept. 7, 1895.

In his process for obtaining ammonia by the partial combustion of fuel containing nitrogen, with a mixture of air and steam (this Journal, 1886, 235—236; and 1896, 529), the patentee proposed to utilise the heat of this combustion to generate a part of the steam required, and to employ the generated gas from which the ammonia, tar, and steam had been separated, for driving gas-motors.

He now proposes to utilise the waste heat of the exhaust gases of these engines to further heat and load with moisture the mixture of air and steam to be used for the partial combustion of the fuel. This is carried out by alternately passing downwards, through towers or cylinders loosely filled with refractory material, the waste exhaust gases from the engines, and when the refractory material is rendered sufficiently hot, allowing water to pass over it and leading off the steam so formed. Whilst the water is passing downwards and the steam being generated, a current of air may also be admitted at the bottom of the towers and the mixture of air and steam be led off near the top of the chambers.—L. T. T.

Peat Charcoal, An Improved Method of Producing, and Apparatus therefor. O. Rose, Brixton, Surrey. Eng. Pat. 17,568, Sept. 20, 1895.

The peat to be made into charcoal is preferably dried, as described in Eng. Pat. 14,533, 1895, and is then charged into a set of retorts, being passed through each in succession. The retorts are arranged in two horizontal rows of two each. Each retort is the same in length, but the diameters decrease in order from the first, the hottest one, to the last. Within each retort is a hollow shaft about half its diameter, having on its periphery a worm-screw thread, either continuous or broken, and on each side alternately of the thread, and at about every third part of a convolution thereon, is fixed a wedge-shaped projection or blade. The shafts are rotated in the desired direction by ordinary spur gearing. Each retort is provided with a separate outlet for gases or vapours, leading to exhausters

and condensers, whereby the volatile products can be collected, and the process carried on under reduced pressure. The retorts are so fired that the flames from one circulate and do duty under and around the next, and so on to the chimney flue. The first retort being heated to about 900° or 1,000° F., the process is started, the retorts being about half-full of peat. The action of the rotating shafts and worm-screw and blades thereon, results in driving the contents of the first retort towards one end, and forcing it upwards into the second retort, along which it passes to the opposite end. It is next forced through a side opening into the third retort, from which, after passing to its opposite end, it falls into the last retort, and, after travelling to the opposite end, is discharged. The product is afterwards made, if desired, into briquettes.—R. S.

"Spraying" Liquids [Liquid Fuel] under Pressure, Impts. in Apparatus for. L. Rusden and R. Eccles, both of Newcastle-upon-Tyne. Eng. Pat. 17,938, Sept. 25, 1895.

The apparatus consists of:—

Spraying Device.—A central liquid-oil chamber receiving oil under pressure, with an annular steam or gas chamber surrounding it. The oil is caused to have a centrifugal motion by the device adopted. The steam or oil-gas is discharged through an annular "mitre"-shaped orifice surrounding the nozzle, the quantity being regulated by a "mitre"-shaped plug, which can be opened or closed by an external hand-wheel.

Automatic Valve.—This adjusts and keeps uniform the pressure on the liquid fuel delivered to the spraying device.

Gas and Oil Separator.—Where the oil passes through a heating coil, so as to generate gas to be used instead of steam in the spraying device, the oil and gas are separated by passing them together into a vertical cylinder furnished with a "float" which in its normal position opens a valve to allow the gas only to pass "onwards," while the oil flows out through the lower end. Both then pass to the sprayer by way of a hinge connection piece, so that the burner can be readily withdrawn from the furnace when necessary.

Accumulator.—The oil, before passing to the sprayer, enters a receiver which forms an air vessel or elastic accumulator, the pressure on the liquid fuel being kept uniform by means of the valve above.—R. S.

Liquid Fuel, An Apparatus for Projecting it intimately mixed with Air and Steam, in a State to be Burnt for Heating Steam Boilers and for other Purposes. C. J. Fox, King's Cross Road, London. Eng. Pat. 18,248, Sept. 30, 1895.

"A LIQUID fuel projector is employed, in which the central air passage is surrounded by an annulus from which liquid fuel issues, this again being surrounded by an annulus supplied with steam, which issues as a tubular jet, and carries forward with it, as a compound combustible jet, the liquid fuel and air."—R. S.

Cyanides and other Compounds, Improved Process for the Extraction of, from Illuminating and other Gases. F. Livesey, London. Eng. Pat. 18,334, Oct. 1, 1895.

The apparatus employed consists of a close cylinder, provided with perforated rotating discs in combination with pockets, which at each revolution of the shaft carrying the discs, dip into a suitable liquid for absorbing the compounds to be removed, and deliver it in thin films as they rise, which descending films of liquid intercept the passage of the gases, these being led through the perforated discs.—E. S.

Coke Ovens, Impts. in Horizontal. A. Hüssener, Essen a Ruhr, Prussia. Eng. Pat. 6999, March 31, 1896.

This invention relates to horizontal coke ovens having horizontal heating channels, and worked for the extraction of the by-products, the improvements consisting in the arrangement of the heating channels or flues and of the partition walls between each two coking chambers, and, where heated air is used, the arrangement of channels for heating it. Each oven chamber has two separate heating-channel systems, one on the right, the other on the left, and each consisting of a sole channel through which the heating-

gases pass, and from which they ascend to the highest of a series of four zig-zag communicating horizontal wall channels, the lowest of which is a waste-heat connecting channel leading to a common waste-heat collecting channel. The partition wall between each pair of oven chambers consists of a central massive wall, taking the whole pressure of the superstructure and of the oven arch, with projections on each side for supporting thin slabs serving as the side wall of the oven chamber, and leaving spaces between itself and the central wall forming the heating channels. Where heated air is employed, the waste-heat collecting channels have air channels arranged between them in the lower part of the foundation of the oven, extending at one end through the front wall to the open air, and communicating at the other end with pipes for leading the heated air to the gas supply entering the heating channels.—R. S.

Gas-enriching Apparatus, Impts. in. G. G. Schroeder, Washington, D.C., U.S.A. Eng. Pat. 7226, April 2, 1896.

This consists of a carburettor, with two compartments, the one containing the oil for carburetting, the other filled with sponge saturated with any suitable purifying liquid. The gas to be carburetted is introduced into the oil compartment through a "vertically swinging gas-supply pipe" which ends in a hemispherical deflecting plate with a float attached. This ensures that the gas always passes through the same thickness of carburetting oil, and also actuates a valve on the oil supply, and so keeps the level of the oil constant.—L. T. T.

Gas, Lighting and Heating, Impts. in Apparatus for Making. J. Sibley, Westerham, Kent. Eng. Pat. 9922, May 9, 1896.

A MODIFICATION of an oil-gas plant intended for country houses and small installations.—L. T. T.

Scrubber Washers for removing Impurities from Gas, Impts. in. H. Kirkham, London. Eng. Pat. 10,822, May 19, 1896.

IN some scrubbers, drums or wheels comprising metal discs having between them, material to afford additional scrubbing surface, are caused to rotate in closed tanks having in their lower parts water or liquor, in passing through which the scrubbing surfaces are wetted preparatory to the gas flowing in contact with such surfaces. It is proposed in such scrubbers to enclose the said material in specially constructed and easily removable cages or baskets fitting between the said discs. The material may thus be more easily renewed.—L. T. T.

Hoods, Mantles, or Gratings for Incandescent Gas-Lights. W. L. Voelker, Elizabeth, New Jersey, U.S.A. Eng. Pat. 13,256, June 16, 1896.

THE object of this invention is to make the filament of which the mantle is composed of such tensile strength that it can be easily handled by ordinary weaving or braiding machinery. The filament is formed in the usual manner, as by combining the incandescing oxide with a viscous material, and is then, when sufficiently dry, covered with a thin cotton braid; or it may be by right- and left-hand spiral winding; or strands of cotton yarn or other combustible fibres may be placed along the filament, and the cover afterwards run on spirally.—R. S.

Acetylene Gas-Generator and Container, A New and Improved. F. S. Thorn and C. Hoddle, both of London. Eng. Pat. 3142, Feb. 12, 1896.

The generator consists of a bell-gasometer having the carbide in a perforated vessel, fastened to and depending from the dome of the bell. If excess of acetylene accumulates in the generator, the bell is raised and the carbide simultaneously removed from the water.—L. T. T.

Acetylene Gas, Improved Process and Apparatus for Purifying [Scrubbing with Alkaline and Acid Solutions]. E. F. J. C. Pauweraerts, Brussels. Eng. Pat. 11,706, May 29, 1896.

This purifying process consists: "First, in cooling the acetylene gas, and in absorbing the impurities thereof by

means of a suitable absorbing agent, such as caustic lime or lime hydrate saturated with sulphate of iron and mixed with sawdust. Secondly, in passing the gas through water which has been acidulated with 50 per cent. of hydrochloric, nitric, acetic, citric, or salicylic acid for the purpose of removing the ammonia from the gas. Thirdly, in removing the acidity of the gas by means of a suitable absorbent, such as caustic soda or potash; and, fourthly, in drying the gas in a suitable material, such as sawdust, bran, or other absorbent material."

It is claimed that the gas so purified is improved in illuminating power, free from smokiness, and may safely be liquefied in an ordinary compression pump.—L. T. T.

Acetylene Gas, Apparatus [Two Connected Vertical Chambers] for the Generation of. E. F. J. C. Bauweraerts, Brussels. Eng. Pat. 11,708, May 29, 1896.

This consists of two vertical chambers communicating at top and bottom, the bottom connecting pipe having a tap or valve in it. The carbide is placed in a pail having grooved perforations; the water is placed in the other vertical chamber, and is admitted by the valve in the communicating pipe.—L. T. T.

Acetylene Gas [Generator], Impts. in the Manufacture or Production of, and in Apparatus therefor. H. A. Derooy, jun., Paris. Eng. Pat. 12,683, June 9, 1896.

This apparatus consists of two or more chambers containing the carbide in perforated pails or other suitable removable vessels, and so arranged that as one chamber becomes exhausted, the water is intended to pass on to the second.—L. T. T.

Hoods or Mantles for Incandescence Gas-Lights, Process of Manufacturing. W. L. Voelker, Elizabeth, New Jersey, U.S.A. Eng. Pat. 13,255, June 16, 1896.

The hoods are partially dried and then put into a furnace which is hotter than that of the flame to which they will be subjected when in use. The required temperature of the furnace is about 3,500° to 4,000° F. By rapidly heating the mantles to this temperature, they are not distorted in shape, and when in use on burners the flame has no perceptible destructive action thereon. The hoods are preferably heated in batches of from 25 to 30 in a gas furnace, such as one used for melting platinum, which is only just large enough to take the batch.—R. S.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

Aluminium Chloride, Action of, on Benzene containing Thiophene. E. Boedtker. Comptes rend. 1896, 123, 310—311.

In preparing cumene by Friedel and Crafts' reaction from the so-called "crystallisable benzene" of commerce, the author has always observed a considerable disengagement of hydrogen sulphide; this he attributes to the presence of thiophene, which he always finds to be present in such benzene. When the benzene is heated with aluminium chloride, hydrogen sulphide and hydrogen chloride are disengaged, and if the product be washed with water and the benzene removed by distillation, a brown fluorescent liquid is obtained, which boils above 300°. This substance contains traces of sulphur, but it does not give the thiophene reaction. The author believes it to contain both the benzene and thiophene nuclei.—A. K. M.

Petroleum Products, Influence of Sunlight and Air on. Capacity of Petroleum for Absorbing Atmospheric Constituents. R. A. Ostrejko. Trudy bak. otd. imp. russk. techn. obschtsch. 1896, 10, [6], 1.

In the continuation of his researches (this Journal, 1896, 26 and 345), the author found that crude solar oil distillate under the same conditions, absorbed the air in the eudiometer tube in 12 days, and deepened in colour from 3 to 2 mm. on the colorimeter scale in 40 days, whereas refined

distillates required in one case 14, and in another 41 days for the absorption of the air, the colour changing from 33 to 7 mm. and from 58 to 6½ mm. respectively: the acidity was about double.

The experiments were also extended to the absorptive capacity of petroleum for carbon dioxide, nitrogen, oxygen, hydrogen, and nitrogen monoxide. At the end of 9 hours' exposure in the dark, nitrogen monoxide, carbon dioxide, and oxygen were found to have decreased in volume, but the converse was noticed with nitrogen and hydrogen, and the same results were obtained by a further 32½ hours' exposure in the dark. On the admission of light, absorption proceeded in all cases, the following times being required for completion: nitrous oxide, 3½ hours; carbon dioxide, 4 hours; oxygen, 8 hours; nitrogen, 2 days (1 hour longer than air); hydrogen, 4 days. This faculty of petroleum for absorbing gases may exert an influence on its composition; e.g., oxygen may be absorbed from underground- or rain-water by contact, and thus form petroleum acids, and it may be that other chemical substances are communicated to the oil in a similar manner, the probability of which discounts the value of hypotheses on the origin of petroleum based on its chemical composition.—C. S.

Ammoniacal Gas Liquors, Desulphurising. Chevalet. Rev. Chim. industr. 7, [79], 203.

The presence of sulphur in the crude ammoniacal liquor from gasworks is prejudicial to the quality of the nitrate and chloride of ammonium manufactured therefrom, causing, in the former case, nitrites—undesirable in powder on account of their hygroscopicity—and, in the latter, thiocyanate of ammonium, which, on account of its decomposability by the electric current, unfits the ammonium chloride for telegraphic purposes. The sulphur may, however, be readily and cheaply removed by allowing the liquor to pass slowly through a scrubber containing iron turnings oxidised in moist air (instead of the ordinary wood shavings), the iron oxide combining with the sulphur in the liquor. The operation may be rendered continuous by passing a current of air through the scrubber to oxidise and regenerate the sulphide of iron. To prevent loss of ammonia by this aeration, a small scrubber containing wood shavings moistened with water is connected with the apparatus.

The effluent liquor is clear, and has lost all trace of sulphur. When treated with lime, the ammonia obtained is purer than that from crude liquor, and does not smell of gas; and when distilled with sodium carbonate, the concentrated liquors are free from thiocyanates, which remain in combination with sodium in the residual liquid.—C. S.

IV.—COLOURING MATTERS AND DYES.

Benzylated Parafuchsin. M. Prud'homme. Bull. Soc. Ind. Mulhouse, 1896, 251—259.

THE influence of benzyl groups on the colours of the substitution derivatives of parafuchsin, is less than that of methyl groups.

The compounds which are produced when the dehydrating agent employed for the preparation of the leuco compounds is sulphuric acid, differ in colour from those prepared by the use of alcoholic hydrochloric acid or zinc chloride.—E. B.

Safranines, Constitution of. O. Fischer. Ber. 29, 1870—1873.

COMMENTING ON Nietzki's last paper (this Journal, 1896, 537), the author points out that the sole argument in support of the azonium formula is the strong basicity especially of the acetyl safranines. It has, however, been shown by Fischer and Hepp that the supposed strong basicity of this class of compounds is delusive, the similarity in colour of the salts and bases, and the solubility in water of certain safranine bases, appearing to support this view. The author has decomposed with dilute sodium carbonate the hydrochlorides of acetylposafranine, diacetylphenosafranine, and acetylrosinduline. The last-named salt, which is yellow, is directly decomposed by sodium carbonate solution, the base separating as a violet-red precipitate, which becomes crystalline and bronzy on standing. In the case of acetylposafranine hydrochloride, the addition of soda-lye in strong solutions gives evidence of decomposition by the change of colour, but even with weak solutions (1:1,000) and also with sodium carbonate decomposition takes place, and may be demonstrated by extracting the base with ether. It is, however, not clear why certain salts of the safranines, especially the carbonates, are not at once decomposed. Possibly it is an inherent property of the *p*-quinone group, or it may be that the phenazine molecule has acquired pyridine properties owing to the attachment of a phenyl group to a nitrogen. The following facts support the *p*-quinonoid formula for the safranines:—1. Their formation from the indamines. 2. Their easy conversion into anilides, &c., similar to the conversion of *p*-quinone into quinone anilide. 3. Aposafranine contains no hydroxyl. 4. Safranin only contains one hydroxyl. 5. Aposafranine is a weak base. 6. No free amino group can be detected in the salt of aposafranine. 7. The formation of an inner anhydride between the ammonium hydroxide and an amino group in the meta position according to Nietzki's view, is improbable.—T. A. L.

Phenazine, Formation of. O. Fischer. Ber. 29, 1873—1876.

THE method employed by the author and O. Heiler (Ber. 26, 383; this Journal, 1893, 751) for obtaining phenazine by heating *o*-amidodiphenylamine with lead oxide has been applied for the production of other azine derivatives. By reducing *o*-nitrophenyltoluidine (Schiff, Ber. 23, 1842; this Journal, 1890, 931) with alcoholic ammonium sulphide under pressure at 120° C., *o*-amidophenyl-*p*-tolylamine is obtained, which crystallises from petroleum ether in plates melting at 76—77° C. When distilled over red-hot lead oxide, *p*-tolylphenazine is formed, which melts at 117° C.,

identical with the product obtained by condensing pyro-catechin with *o*-tolylene diamine (Ber. 19, 726). By oxidising diamidodiphenylamine—

Nietzki and Bauer (Ber. 28, 2979) obtained the *p*-amido-phenazine of Fischer and Hepp, but could not obtain it from the isomeric compound (4.2.1)(NH₂)₂.C₆H₃.NH.C₆H₄. Nietzki concluded from this that a diphenylamine in which one nucleus was unsubstituted, or only substituted in the meta position, could not give an indamine or an azine. The author, however, finds that the lead oxide method easily gives amidophenazine, melting at 274° C. (F. and H., 265° C.). In the same manner, dinitro-*p*-methoxydiphenylamine (from bromodinitrobenzene and *p*-anisidine), melting at 141° C., after reduction to diamido-*p*-methoxydiphenylamine, melting at 119° C., gives, on heating with lead oxide, *p*-amidomethoxyphenazine—

melting at 217° C., which is the methyl ether of the amido-oxyphenazine, melting at 268° C., obtained by Nietzki and Simon (Ber. 28, 2975).—T. A. L.

Chloracetylpyrogallol, Action of Benzaldehyde on. L. Kesselkaul and St. v. Kostanecki. Ber. 29, 1886—1891.

IN a paper on the preparation of flavone derivatives, Friedländer and Rüdert (Ber. 29, 878) have described a compound as 3,4-dihydroxyflavone, which they obtained by the action of benzaldehyde on chloracetylpyrogallol. In view of Kostanecki and Tambor's work (Ber. 29, 237), this conclusion was open to objection, and the compound obtained is an oxindogenide of the formula—

This substance, benzalanhydroglyceogallol, which the authors have prepared, crystallises in golden-yellow plates melting at 221° C. It is not an oxyflavone, since it gives orange shades on an alumina mordant, and dissolves in concentrated sulphuric acid with a deep orange colour, whilst all known oxyxanthones and oxyflavones dissolve with a pure yellow colour, giving occasionally fluorescent solutions. The diacetyl derivative and the diethyl ether of the compound have been prepared, the former (colourless needles) melting at 201° C., and the latter (yellow needles) at 115° C. The product has also been obtained by the action of benzaldehyde on anhydroglyceogallol. Since the oxindogenides like the indogenides are coloured, it would appear that the chromogen of indigo is—

of which the synthesis has been undertaken. This substance contains an open α -naphthoquinone ring, a fact which may have some bearing on the colouring properties of indigo.

—T. A. L.

Quercetin [Dye-stuff] in the Outer Skins of the Bulb of the Onion (Allium Cepa). A. G. Perkin and J. J. Hummel. Proc. Chem. Soc. 1896, [168], 144—148.

LEITCH (Farben und Färbekunde, 1825, 1, 431) has described the dyeing properties of these skins. The colouring matter was obtained by the authors in the form of glistening yellow needles of the formula C₁₅H₁₀O₇, which yielded compounds with mineral acids; the sulphuric acid compound C₁₅H₁₀O₇.H₂SO₄ was analysed. On acetylation, a compound, C₁₅H₁₀O₇.(C₂H₃O)₅, forming colourless needles, melting point 190—191°, was obtained, and by decomposition with fused alkali, phloroglucin and protocatechuic acid formed the principal products. With mordants it dyed shades similar to those given by quercetin, the colouring matter of quercitron bark. It was thus proved to be identical with this substance.

Comparative dyeing experiments showed that the colouring matter of onion skins was quite equal to that of such well-known dyestuffs as old fustic and quercitron bark.

Sicilian Sumach, The Colouring Matter of, Rhus Coriaria. A. G. Perkin and G. Y. Allen. Proc. Chem. Soc. 1896, [168], 157.

SUMACH, which consists of the dried and powdered leaves of the genus *Rhus*, especially *R. coriaria* (Sicilian), and *R. cotinus* (Venetian sumach), is used in tanning, and also in dyeing and calico printing, on account of the tannin matter it contains, which according to Lowe is gallotannic acid (Fresenius, Zeit. anal. Chem. 12, 128). According also to Chevreul, it contains a yellow colouring matter (Watts' Diet. Chem. 1874, 5, 614). Lowe (Zeit. anal. Chem. 12, 127), who examined the different varieties of sumach, stated that they contain quercetin and quercitrin, but this is certainly incorrect as regards Sicilian sumach.

The colouring matter, $C_{15}H_{10}O_8$, forms glistening yellow needles, having dyeing properties similar to those of quercetin and fisetin, but is distinguished from these by its colour reactions with dilute alkalis. Reactions show it to be identical with *myricetin*, the colouring matter of *Myrica nagi*. Sicilian sumach also contains some quantity of free gallic acid.

PATENTS.

New Diamido Bases, Derivatives of Azimidobenzene and of Azo [Cotton] Dyes from these. Manufacture of. O. Imray, London. From "The Farbwerke vormals Meister, Lucius, and Brüning," Hoechst-on-the-Maine, Germany. Eng. Pat. 17,639, Sept. 21, 1895.

THE bases employed are obtained from the products formed by the action of 2,4-dinitrochlorobenzene on aniline or *o*-toluidine, yielding 2,4-dinitrodiphenylamine—

melting at 156° C., and 2,4-dinitrophenyl-*o*-tolylamine—

of which the correct melting point is 123° C. On reduction with an alkaline reducing agent in alcoholic solution, only the nitro group adjacent to the imido group is reduced, yielding respectively nitro-amidodiphenylamine (dark red needles and plates from alcohol), melting at 117° C., and the corresponding tolylamine derivative, melting at 121° C. Both these substances, when treated with nitrous acid, yield azimidobenzene derivatives, melting at 167° C. and 115° C. respectively. On nitration in sulphuric acid solution, corresponding dinitro compounds are obtained, melting at 190° C. and 201° C. Finally, these substances, on reduction, are converted into diamido bases which melt at 153° C. and 155° C., and, after conversion into their tetrazo derivatives, can be combined in the usual manner with amines, phenols, and their derivatives. For instance, one molecular proportion of the tetrazo compound can be combined either with two similar or different molecular proportions of a dyestuff component yielding yellow, red, violet, or orange dyestuffs. If, however, the tetrazo compounds be first combined with α -naphthylamine, its 1,3' or 1,2' sulphonie acids, or with such derivatives capable, after combination, of further diazotisation, then on treatment with nitrous acid, diazo compounds are obtained which, when combined with the usual components, yield blue and violet to black dyestuffs. The second diazotisation can be performed on the fibre. By combining the tetrazotised diamido bases with dihydroxynaphthalene mono- or disulphonie acid or with an amidonaphthol mono- or disulphonie acid, products are obtained, which will combine with one or two molecular proportions of a diazotised amine or its sulphonie acid. Different products are obtained according as to whether the combinations are carried out in an alkaline solution or in presence of acetic acid. The colouring matters obtained according to this invention are said to be fast to light and soap, and are suitable for dyeing evenly, not only un mordanted cotton, but also mixed goods, such as half wool and half silk. —T. A. L.

New Mordant-dyeing Colouring Matters [Yellow], The Manufacture and Production of. B. Willeox, London. From "The Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 17,660, Sept. 21, 1895.

THESE colouring matters are obtained by oxidising aromatic hydroxycarboxylic acids in sulphuric acid solution, either by means of a persulphate or by an electric current (see also Eng. Pat. 17,260, 1895; this Journal, 1896, 588). About 10 kilos. of symmetrical *m*-dihydroxybenzoic acid are dissolved in 200 kilos. of cold sulphuric acid of 95 per cent., and 15 kilos. of ammonium persulphate are added to the solution, the temperature being kept below 50° C. After 12 hours' agitation, the melt is stirred into 1,000 litres of water, and the colouring matter is filtered off, being kept for use in the form of a paste. According to the electrolytic process, 10 kilos. of the dihydroxybenzoic acid dissolved in 40 kilos. of 63 per cent. sulphuric acid are placed in the electrolytic cell containing the positive electrode. The negative electrode, separated by a suitable diaphragm, is immersed in sulphuric acid. An electric current of 20 amperes per sq. dec. of anode surface at about 8 volts, is passed through the solution, which is kept constantly agitated and at about 25° C. When the reaction is complete, the melt is poured into water and worked up as above. The resulting product is identical, and gives strong, fast yellow shades on wool mordanted with chrome or alumina. Cotton mordanted with alumina is also dyed yellow. The colouring matter, which is scarcely soluble in water even on boiling, forms a yellow or greenish-yellow paste which dries to a greenish-yellow powder soluble in and crystallisable from alcohol or glacial acetic acid. The following acids can also be employed for the purpose of this invention: salicylic acid, *m*- and *p*-hydroxybenzoic acid, cresotic acid, symmetrical *m*-dihydroxybenzoic ethyl ether or anilide, gallic acid, gallic ethyl ether, gallamic acid, gallanilide, tannin, protocatechuic acid, β -resoreylic acid, or the like. —T. A. L.

Sulpho Acid which may be Employed in the Production of Colouring Matters, Impts. in the Manufacture of. I. Levinstein and Levinstein, Ltd., Manchester. Eng. Pat. 20,548, Oct. 31, 1895.

By heating dihydroxynaphthalene sulphonie acid G (Eng. Pat. 9642 of 1889; this Journal, 1890, 609) with aniline and aniline hydrochloride or with toluidine and toluidine hydrochloride, one hydroxyl group is replaced, and there results phenyl- or tolylamidonaphthol sulphonie acid. For instance, 26 kilos. of the sodium salt of dihydroxynaphthalene sulphonie acid G, 25 kilos. of aniline hydrochloride, and 100 kilos. of aniline, are heated to 160° C. for 2—3 hours. The melt having been made alkaline, the excess of aniline is driven off, and the filtered solution is run into water acidulated with hydrochloric acid. The phenylamidonaphthol sulphonie acid separates out as a grey precipitate, and, after filtering and washing, may be used directly for the production of azo dyestuffs. A colouring matter dyeing unmordanted cotton olive-brown, is obtained by combining tetrazotised dianisidine with salicylic acid and aniline, diazotising the product so obtained, and combining this with an alkaline solution of phenylamidonaphthol sulphonie acid. —T. A. L.

Substantive Cotton Dyestuffs from Benzidine Sulpho-Acids, Manufacture of. H. Inray, London. From F. Petersen and Co., Schweizerhalle, Bâle, Switzerland. Eng. Pat. 13,713, June 22, 1896.

THE benzidine sulphonie acids of Griess (Ber. 14, 200), when combined with γ -amidonaphthol sulphonie acid, yield products which, after diazotisation and combination with various components, give valuable colouring matters, which in some cases are considerably stronger than the corresponding derivatives obtained from the non-sulphonated benzidine base. The diazotisation and development can also take place on the fibre by dyeing the fabric with the colouring matter obtained from the tetrazotised benzidine sulphonie acid and γ -amidonaphthol sulphonie acid. The two sulphonie acids of Griess produce very similar effects, but slightly bluer shades are obtained from the more soluble acid. A blue-black colouring matter for cotton fast to

light and washing, is formed by combining the tetrazo compound from one of the Griess sulphonic acids, corresponding to 10 kilos. of nitrite with an alkaline solution of 34 kilos. of 7-amidonaphthol sulphonic acid. The new intermediate compound, after diazotisation, is combined with 23 kilos. of *m*-phenylenediamine, when it forms a black precipitate. The dyestuff is readily soluble in water, but insoluble in alcohol. It dissolves in sulphuric acid to a bluish-green solution, which gives a black precipitate on dilution. The reddish-brown aqueous solution gives a reddish-brown precipitate with hydrochloric acid, and a brown precipitate with caustic soda.—T. A. L.

New Disazo, Trisazo, and Polyazo [Blue and Black] Colouring Matters, Manufacture of. O. Imray, London. From "The Society of Chemical Industry in Basle," Basle, Switzerland. Eng. Pat. 13,744, June 22, 1896.

By combining diazo compounds of the general formula $(1.N:N.C_6H_4.COX)$ (in which X may be hydrogen, a hydroxyl, an alkoxy, an amido, alkyl, or alkyl-amido group), with the 1.1'.3.3', 1.1'.4.3', or 1.4'.3.2' amidonaphthol disulphonic acids, products are obtained, which, although of little value as colouring matters, can be employed for the production of disazo, trisazo, and polyazo dyestuffs. The diazo compounds are obtained from the *o*-, *m*-, and *p*-amidobenzaldehydes, the *o*-, *m*-, and *p*-amidobenzoic acids, their ethers and amides, and, after combination with one of the above-named acids, an azo colouring matter of the general formula $XOC.C_6H_4.N:N.C_{10}H_7(OH)(NH_2)(SO_3Na)_2$ is obtained. These products act as a dyestuff component in a diazo or tetrazo combination, and they may be employed in the various stages usual in such combinations. Since also they contain a CO group, they are capable of reacting with aromatic hydrazines, and the hydrazone azo-colouring matters thus obtained dye unmordanted cotton and wool heavy dark blue, black, and green shades. The specification contains a large number of examples, of which the following may be taken as typical. (1.) The product obtained by combining the diazo compound from 6.1 kilos. of *p*-amidobenzaldehyde with 16 kilos. of 1.1'.3.3' amidonaphthol disulphonic acid is combined in a solution made alkaline with sodium carbonate with the tetrazo-ditolyt obtained from 10.6 kilos. of toluidine. When the formation of the intermediate product is complete, a solution of 6.5 kilos. of *m*-tolenylenediamine is added and allowed to stand 12 hours, when the colouring matter is separated in the usual manner. It dyes unmordanted cotton black. (2.) The diazo compound from 6.1 kilos. of *p*-amidobenzaldehyde is combined with 16 kilos. of amidonaphthol sulphonic acid in acetic acid solution; when the combination is complete, 5.4 kilos. of phenylhydrazine are added and the whole is heated to 60–70° C. for two hours, when the red colour of the solution gradually changes to blue. After making alkaline with sodium carbonate and cooling, the tetrazo solution from 9.2 kilos. of benzidine is run in. The formation of the intermediate compound is complete in about two hours, when it is mixed with a solution of 16 kilos. of 1.1'.3.3'-amidonaphthol sulphonic acid, made alkaline with sodium carbonate. After standing a considerable time, the whole is heated, and the colouring matter is salted out, filter-pressed, and dried. It dyes unmordanted cotton blue.—T. A. L.

V.—TEXTILES: COTTON, WOOL, SILK, Etc.

Woollen Goods, Use of Ammonia in Washing. Textile Colorist, 1896, 18, 207.

IN using ammonia for washing woollen goods after fulling, part of the diluted ammonia is added at the beginning to loosen the dirt, and part when most of the dirt and lather have been washed out; this second addition assists the removal of the soap. Some ammonia may also be added to the solution of fuller's earth used for the final washing. The strength of the ammonia used, varies with the different shades, i.e., light shades require weaker ammonia. Reds, especially those dyed with Brazil wood, madder, or cochineal, will not stand washing with ammonia. Care should be

taken that the material, whilst wet with ammonia, does not come into contact with any metallic parts of machinery, &c., as this would occasion dark stains on the pieces.—A. S.

Woollen Goods, Waterproofing of. Textile Colorist, 1896, 18, 206.

THE two principal methods of waterproofing woollen goods are:—

1. Treating the goods upon the washing machine with a solution of aluminium acetate, prepared by making a solution of 3 kilos. of alum and 3 kilos. of lead acetate in 100 to 200 litres of water, allowing to settle, and then drawing off the clear solution of the aluminium acetate.
2. Steep 100 parts of glue (preferably animal glue) in cold water until it has absorbed twice its weight thereof, pour off the excess of water, and heat the glue to boiling. Stir into the boiling glue 5 parts of tannin and 2 parts of silicate of soda, and then add 100 parts of alum dissolved in 100 parts of boiling water. When the ingredients are thoroughly mixed together, allow to cool. Boil 1 kilo. of the gelatinous mass thus obtained, for 3 hours with 10 to 12 kilos. of water, replacing the water which evaporates. Cool down to 80° C., pour into a sizing machine, and pass the goods through. Dry at about 55° C., and finally press upon the cylinder at 50° C.—A. S.

PATENTS.

Removing Tar, Pitch, Oil, Grease, and Similar Matter from Wool, Fur, and the like: An Improved Method of and Apparatus for. S. W. Wilkinson and The Grove Company, Ltd., London. Eng. Pat. 16,143, Aug. 28, 1895.

THE grease, tar, &c., derived from natural or other sources, is extracted by means of a suitable volatile solvent, the most effective being benzol boiling below 100° C. or carbon bisulphide. The felt is placed in a closed vessel which is capable of withstanding a certain amount of pressure, and which can be heated by means of a steam jacket or hot-water coil. This is connected by means of a distributing pipe with a suitable vessel, in which the solvent is heated and volatilised. The felt is permeated by the hot solvent, which subsequently condenses and is siphoned back into the boiler. The solvent remaining in the fibres of the felt after the extraction is complete, is removed by heating the extractor, condensing the vapours, and returning the liquid to the boiler, suitable communicating pipes, with cocks, valves, or the like, being provided for the purpose.

—C. A. M.

Effluent Waters of Wool-washing Machines and the like, New or Improved Method of and Apparatus for Removing Fatty Matters from the. J. Holmes, Bradford; H. E. Tankard and W. Scaife, Laisterdyke. Eng. Pat. 18,239, Sept. 30, 1895.

THE effluent from the washing machine is run into a tank or tanks containing perforated pipes, through which an air blast is driven by means of a fan, blower, or pump. The froth or foam thus produced consists chiefly of the fatty matters. It is collected, preferably, by means of an endless travelling band of wire gauze or other suitable material, whence it is removed by a revolving roller and scraper, and delivered into a suitable receptacle.—C. A. M.

Mineral-Oil Stains, Improved Process for Removing [with Aniline Oil or Phenol], from Vegetable Fabrics. J. Y. Johnson, London. From S. Wallach and Co. and E. Schweitzer, Müllhausen, Alsace. Eng. Pat. 24,643, Dec. 23, 1895.

THIS patent is based on the property possessed by certain substances—such as aniline, crude aniline oil, phenol, and others; also resin oil, Turkey-red oil, and the like—of removing from vegetable fibres the mineral oil stains acquired in the process of weaving. The best results are obtained by using small quantities of aniline, aniline oil, or phenol, which will readily dissolve in a solution of any kind of soap. Cotton fabric may either be steeped in a solution of 6 litres of aniline or aniline oil, 100 litres of water, and 4 to 5 kilos. of soap before being transferred to the bucking

tub, or the pieces of fabric may be placed in the bucking tub or lye-boiler, and the lye with the aniline or other solvent, introduced. From 10 to 15 litres of aniline, or from 6 to 7 litres of phenol, will generally suffice for 2,000 kilos. of material. It is claimed that material thus treated acquires far less yellow tinge in the process of steaming than do fabrics bleached by the present method, and that the firmness or strength of the fibre is not diminished.

—C. A. M.

VI.—DYEING, CALICO PRINTING, PAPER-STAINING, AND BLEACHING.

Chlorine Baths [Cotton Bleaching], The Addition of Acid to. Leipziger Färber Zeit. 45, 248.

In order to increase the effectiveness of a bleaching-powder solution, an addition of hydrochloric or sulphuric acid is frequently made. Lunge recommends for this purpose, the use of acetic or other organic acid, *e.g.*, lactic or formic acid. The expense is not great, since, after the first addition, very small further quantities are necessary, the acid being regenerated during the bleaching process. When acetic acid is used, hypochlorous acid and calcium acetate are at first formed; the former during bleaching is converted into hydrochloric acid, which does not remain in the free state, but at once acts upon the calcium acetate, forming calcium chloride and liberating acetic acid. When this process is adopted, the customary "souring" after treatment with bleaching powder can be omitted, thus obviating the risk of tendering the fibre through the action of a mineral acid. Acetic acid may, however, be applied subsequently to the bleaching-powder solution instead of in the same bath, or the goods may be worked in water acidulated with acetic acid and the clear bleaching-powder solution gradually added. When alkali remains in the material from the "ley boil," or when hard water is employed, sulphuric acid may be used in just sufficient quantity to effect neutralisation, the liberation of hypochlorous acid being effected as before by the weaker organic acid.

—R. B. B.

Starch, The Oxidation of [for Cotton Finishing].

O Schmerber. Bull. Soc. Ind. Mulhouse, 1896, 238—241.

With a view to effect the oxidation of starch by purely chemical means, the author instituted a series of experiments with various oxidising agents, namely, bleaching powder, chloric acid, magnesium dioxide, chromic acid, and potassium permanganate. The last of these was found to give the best result. The method eventually adopted, consists in placing in a vat of 1,000 to 1,500 litres capacity, 100 kilos. of starch and 100 litres of water, stirring to get the starch well into suspension, and then adding a solution of 500 grms. of potassium permanganate in 20 litres of warm water. The mixture becomes successively red-violet, pale brown, and dark brown in colour. It is left for 24 hours, and 4–5 litres of hydrochloric acid, diluted with 20 times as much water, are then added to it. The mixture is stirred whilst the acid is introduced, and at intervals afterwards, until the starch is obtained in a colourless condition. The product is then washed by decantation to remove the acid and manganous chloride, and is dried.

The starch thus oxidised, gives a paste which is more liquid and transparent than that which is obtained from the same starch in its ordinary state. On standing, the paste becomes opaque, but it reassumes its transparency when heated. It is considered probable that oxidised starch will find useful application in the processes of finishing and printing cotton fabrics.—E. B.

Starch, The Oxidation of. E. Dolfus and F. Scheurer.

Bull. Soc. Ind. Mulhouse, 1896, 241—245.

A REPORT on the paper (see preceding abstract) of Schmerber. The authors have repeated the experiments described by that chemist, and find that the starch, treated in the way he recommends, yields a paste, or, rather, a solution which is more liquid and transparent than that yielded by un-oxidised starch. The product appears to be closely related to soluble starch.

Schmerber was led to undertake this study by the results obtained by Siemens and Halske in exposing starch to the action of oxidising agents (prepared by the electrolysis of a solution of sodium and magnesium chlorides).

In connection with the subject, the following references to accounts published by previous investigators are made:—

Persoz (Traité de l'Impression, t. 1, 289).

Hernite (this Journal, 1893, 168). Starch which has been treated by the method alluded to, is stated to be characterised by its remarkable degree of whiteness.

Leitner (Zeits. f. angew. Chem. 1890, 546) mentions the fact that the course of the action of potassium permanganate on starch could be followed by testing with iodine solution, as is done in the process of converting starch into diastase, the colorations obtained with iodine at successive stages of such action with potassium permanganate being blue, violet, violet-red, and reddish-brown. At the next and final stage of oxidation, no coloration is produced. The products are gummy substances which are differentiated from dextrans by their acid reaction and by their yielding precipitates with basic lead acetate and barium hydroxide. On boiling, they expel carbon dioxide from carbonates, and they slightly reduce Fehling's solution.

O. N. Witt and Siemens (this Journal, 1896, 366) also make use of potassium permanganate to effect the purification of starch.

Asbóth (Chem. Zeit. 1892) used hydrogen dioxide and ammonia, and obtained by their action on starch paste, a solution from which soluble starch (termed by Asbóth, amyloextrin) was precipitated by the addition of alcohol, its amount approaching 80 per cent. of the total product.

It is, finally, pointed out that during the past two or three years the weavers in Alsace have made considerable use of sodium dioxide to render their sizes more liquid.

—E. B.

Paranitraniline Red on Cotton Cloth. R. Wieland.

Leipziger Färber- u. Zeugdrucker Zeit. 45, 321—326, 345—346. (See also this Journal, 1896, 111 and 112.)

A PROCESS for producing *p*-nitraniline red on cotton cloth on the large scale is described in detail. The half-bleached goods are padded with a solution of β -naphthol prepared as follows:—

β -naphthol (pure)	2700 kilos.
Sodium hydrate solution, 22° B.	3450 litres.
Turkey-red oil (sodium salt)	8100 "

the whole made up to 180 litres.

The goods should pass twice through this bath, and the pressure of the rollers should be so regulated that the cloth shall take up its own weight of liquor. After padding, the goods must be thoroughly dried in a hot-flue, which may be heated up to 70° C., taking care to avoid creases or folds in the cloth during the drying, as such parts would be of a lighter colour than the rest of the cloth. The turning-in of the edges, to which satens are particularly liable, may be prevented by adding 1 litre of a 10 per cent. tragacanth solution to every 10 litres of naphthol solution.

The trough in which the goods are developed should be as small as possible, the sides sloping downwards. It is provided with three small wooden rollers to guide the cloth through the developing bath, and a pair of squeezing rollers to remove the surplus liquor. The cloth then travels a few yards before being washed, so as to allow the diazo solution to combine with the naphthol. The goods then enter a washing machine, through which they pass continuously and in open width, and must subsequently be well washed in the chain form on a "dolley." A slight soaping with 2 grms. of soap to the litre at 60° C. for, say, 10 minutes imparts to the red a bluish tint.

The diazo solution is prepared as follows:—4.8 kilos. of paranitraniline and 2.45 kilos. of sodium nitrite are made into a paste with 300 c.c. of methylated alcohol and 5 litres of water, using wooden vessels for the purpose. This paste is gradually introduced into a mixture of 9.75 litres of hydrochloric acid of 20° B. and 150 litres of water cooled to —3° C., and after about 10 minutes, the whole is made up to 180 litres.

In a separate vessel are dissolved 8.8 kilos. of sodium hydrate in 50 litres of water and 30 litres of acetic acid of 40 per cent. The solution, which should show a feebly acid reaction, is then made up to 180 litres.

For making up the developing bath, at first, take of—

Diazo solution	1 part.
Acetate „	1 „
Water.....	2 parts.

For subsequent additions, however, three parts of diazo solution and one part of acetate are mixed in a tub placed above the developing trough, and allowed to flow into the latter as required, whilst the cloth is passing through at the rate of about 20 metres per minute.—I. S.

Indigo Vats, Calcium Lactate in. Textile Colorist, 1896, 18, 204.

THE glucose in the indigo vat is first converted into lactic acid by the action of lactic ferment, and the lactic acid is then further acted on by the butyric bacilli with formation of butyric acid, carbon dioxide, and hydrogen. Thus the addition of calcium lactate at the beginning of the operation hastens the action of the vat, as it can be immediately acted on by the butyric bacilli to furnish the hydrogen necessary for reduction. It was found that the proportion of 1 lb. of calcium lactate to 10 or 20 galls. of new vat liquor gave good results.—A. S.

Indigo-dyed Yarn, A New Cause of Unevenness in. Eulenthaler, Leipziger Färber Zeit. 45, 245.

IN the author's dye-works the water for dyeing purposes is taken from a reservoir of 800 cb. m. capacity, and since on the average only about 35 cb. m. are drawn off daily, the water tends to become stagnant. At certain seasons of the year there is found in the reservoir a species of moss from which bubbles of hydrogen are given off. During this period it was frequently noticed that the yarn dyed with indigo had an uneven, "striped" appearance, especially in the case of dark shades which had been dipped several times in the vat and often allowed to lie in the wet state overnight. Since the moss adheres tenaciously to the yarn, and unevenness is shown in the portions of the yarn to which it adheres, the explanation must be sought in the reduction of indigotine brought about by the nascent hydrogen produced during the development of the vegetable growth.—R. B. B.

Silk, Absorption of Dilute Acids by. J. Walker and J. R. Appleyard. Proc. Chem. Soc. 1896, [168], 147.

WHEN silk is dyed with picric acid a real equilibrium is attained which is independent of the original distribution of the materials.

When other solvents than water are used the rate and amount of dyeing with picric acid seem to be connected with the dissociative power of the solvent. Silk will not take up picric acid from benzene or from carbon tetrachloride, but does so readily from alcohol, less readily from ether and acetone. The ratio of the final concentrations of aqueous and alcoholic solutions of picric acid required to dye silk to a given standard, was found to be approximately the ratio of the solubilities of picric acid in water and in alcohol.

A comparison of the extents to which the various acids are absorbed by silk shows that the acids fall into two classes—the aromatic acids where the absorption is great, and the non-aromatic acids where the absorption is relatively small. In each class there is a rough parallelism between the strength of the acids and the amount absorbed. The addition of calcium benzoate to a solution of benzoic acid greatly diminishes the strength of the acid, and the absorption also is thereby much diminished.

If dyeing were a pure chemical addition of the dye to the fibre, the theory of mass-action predicts that the equilibrium concentration of the dye-bath should be constant at any given temperature, independently of the quantities of material taken. This is not known to be the case for actual dyeing, but it was experimentally verified by "dyeing" Diphenylamine brown with picric acid from aqueous solution.

Bichromate, Recovery of, from Spent Aniline Black Liquors. Beltzer. Leipziger Färber- u. Zeugdrucke Zeit. 45, 342.

THE spent chrome liquors, which contain the chromium in the form of its soluble salts (sulphates, chlorides, &c.), are allowed to settle, the clear liquor is decanted and heated, and the chromium precipitated with the calculated quantity of lime, chalk, or an alkali. The precipitate is collected on a filter, mixed with the calculated quantity of an alkali to form a neutral chromate, dried, and roasted in a special furnace. The melt is dissolved in water, converted into the bichromate by the addition of hydrochloric or sulphuric acid, and made up to the required strength again.—I. S.

Aniline Poisoning. Leipziger Färber- u. Zeugdrucker Zeit. 45, 346.

PATENTS.

Dyeing, Washing, and Rinsing Apparatus for Textile Goods, Impts. in. H. Schirp, Barmen, Germany. Eng. Pat. 12,500, June 8, 1896.

THE liquor is taken from and returned to a special reservoir, and by means of a pump is caused to circulate through the dyeing vessel. In the interior of the latter are a number of cones perforated around the apex, and the liquor passing through these perforations is evenly distributed throughout the material. The chief feature of the invention is the insertion in the pipes, which connect the two vessels with the pump, of reversible valves which, when turned through 180°, cause the liquor to circulate in the opposite direction, so that it may be either forced or drawn by suction through the material, and thus, it is claimed, thorough penetration and even dyeing are ensured.—R. B. B.

Colours with Silk-like Gloss, Improved Process and Apparatus for the Production of, on Vegetable Fibres and Textile Fabrics; also on Wool, India-Rubber, Leather, Wood, Metal, and other Substances. E. Heberlein, Wattwil, St. Gallen, Switzerland. Eng. Pat. 13,198, June 15, 1896.

TO produce colours with a silk-like gloss the material is dyed in a cold bath containing collodion together with an alcoholic solution of a basic or phthalein dyestuff. The collodion acts as a mordant, replacing the tannin and tartar emetic of the ordinary process. Direct-dyeing colouring matters may also be employed, but in this case the dye-bath must be heated. Dyeing takes place in a closed vessel partially filled with the solution, through which the yarn or fabric is guided by means of rollers, and the material then passes through a drying chamber. It is claimed for the process that: (1) the threads are strengthened and their weight increased; (2) the colours are more brilliant than when dyed with tannin mordant; (3) the colours are faster, especially to chlorine; and (4) the fibres are stiffened, and fabrics thus treated are rendered waterproof. If softness be required, an addition to the dye-bath of 5–10 per cent. of olive oil must be made.—R. B. B.

Aërating Liquids, Improved Apparatus for, especially applicable to Fermenting Tuns and Indigo Vats. F. Grambacher, Berlin. Eng. Pat. 13,386, June 17, 1896.

See under I., page 641.

VII.—ACIDS, ALKALIS, AND SALTS.

Carbonic Acid, Manufacture and Uses of, in Germany. U.S. Consular Reports, Aug. 1896, 756.

USES.—The industrial uses of carbonic acid may be classified under three general groups—(1) for aërating mineral waters, beer, sparkling wines, and other effervescent beverages; (2) for making various carbonates and other products, such as salicylic acid, in chemical manufacture; and (3) for the manufacture of artificial ice and the cooling of refrigerators and cold-storage chambers.

The consumption of carbonic acid for all these purposes is estimated to have doubled in this country during the past 10 years, and its production has rather more than kept pace with its steadily increasing use. Complete statistics for the past two years are not available, but in 1891, 23 firms produced 6,600,000 lb. of liquid carbonic acid, and in 1892 the exports of that material amounted to 2,053,360 lb. There are now 28 firms and syndicates engaged in the manufacture, with a steadily increasing output, and the business seems to be active and prosperous.

When produced artificially, carbonic acid gas is usually tainted by impurities, so that the gas used for making pure chemicals and for aerating mineral waters, beer, wines, &c. is now generally obtained in Germany from the decomposition of magnesite, or still more from natural carbonic acid springs, which exist abundantly in the Lower Rhine region, between Mayence and Cologne. Many of the springs have been known for centuries, but their importance as sources of carbonic acid dates from only a few years ago, when the process of condensing the gas into liquid form was perfected, and it became thereby a cheap and convenient commercial product.

1. *Natural Carbonic Acid.*—There are, in the Lower Rhine country, hundreds of springs—including such well-known sources as the Apollinaris, Selters, Kronthal, Ems, and Nauheim springs—which yield waters more or less overcharged with carbonic acid gas. Where the gas is in excess, it escapes in the ebullition of the fountain, which, being securely inclosed, the surplus gas is collected and either condensed into liquid dioxide or used directly for impregnating natural mineral waters which have other valuable qualities, but are deficient in effervescence. Where, as is often the case, the water is impure or wanting in medicinal qualities, it is run to waste, and the spring utilised only for its carbonic acid gas.

From the time when the manufacture of liquid carbon dioxide became an established industry, the supply of gas from natural springs became inadequate, and recourse was had to artificial borings. The first artesian well for this purpose was sunk at Burgbrohl, a few miles westward from the Rhine, below Coblenz, in 1883, and was only 5½ ins. in diameter. At a depth of 171 ft., a vein was reached, from which spouted up a stream, 25 ft. in height, that yielded 108 galls. of water per minute and 375 galls. of dry carbonic acid gas. It continued to flow at this rate until 1891, a period of eight years, during which time there was condensed from the gas of that single well 1,394,800 lb. of liquid carbonic acid. Its yield was regular and constant until 1891, when a similar well was bored, still deeper, at a distance of 130 ft. from the original one. This tapped the same source of supply, and from that time the older well declined somewhat in its yield, but it is still in use. Since then other wells have been bored at various points in the surrounding region, notably at Hönningen and Linz, near Coblenz, and within the past few weeks a remarkable one has been opened at Herste, near Driburg, in the north-eastern part of Westphalia.

It was noticed some time ago that gases which would extinguish a lighted match or candle were rising from holes and crevices in the ground, and that the small pools of water thereabouts were frequently in ebullition. Boring was accordingly begun, and at a depth of 25 ft. the outflow of gas became so profuse that the workmen were in danger of suffocation. Means were adopted to divert this outflow, and the boring proceeded until, at a depth of 438 ft., there was an explosion. Bore dust, pebbles, &c. were blown out to a height of 70 ft., accompanied by a stream of gas so powerful that the roar of its escape could be heard at a long distance. Thus far the well had been quite dry, and work was continued under great difficulties, until, at a depth of 485 ft., a vein of water was struck, which rushed out as finely-atomised spray to a height of nearly 100 ft., yielding 88 galls. of water per minute. The well has since been cased with an iron pipe, which conducts the outflow into a large reservoir, where the water separates by gravity from the gas, which is then forced into compressors and condensed to liquid carbonic acid. One measure of liquid contains 430 measures of gas.

This well is interesting as an illustration of the fact that, as usual, the strata through which it was bored have no apparent relation to the gas which it yields. The conclusion is inevitable that the carbonic acid is developed at a great depth, and wholly independently of the overlying geological strata, through which it escapes to the surface.

The present market price of liquid carbonic acid condensed from natural gas, and supplied by the above method, is 11 cents per kilo., equal to 5 cents per American lb. From this general rate there is granted a discount of something more than half a cent. per kilo. to customers whose orders aggregate more than 500 kilos. (1,102 lb.) within a calendar year. This discount is 2½ cents per kilo. to consumers of 1,000 kilos., and 4 cents per kilo. to consumers of 5,000 kilos. or more per year. It will thus be seen that large purchasers, who buy for their own use or for export more than 5 tons of acid from the same syndicate within a year, can obtain it for a minimum price of about 7 cents per kilo. (3.17 cents per lb.). Rates like these for carbonic acid of warranted purity naturally control the market, and have contributed largely to the greatly increased use of this material during the past 10 years.

The use of carbonic acid in connection with beer is as follows:—The thing desired was a latent and easily controlled force which, without injuring the quality of the beer, should lift it from the storage cask in the cellar to the faucets above, where it is drawn for consumption. For this purpose the flask containing the liquid dioxide is connected with a reservoir which is provided with a manometer and adjustable pipes to convey the gas into the cask or casks in which the beer is kept on draught. These connections being adjusted, a small quantity of acid is let into the reservoir, where it expands at once into gas with development of cold. When the manometer shows a pressure of 2 atmospheres, the supply of acid is shut off, and the generated gas, passing through the pipe into the cask, acts as a steady, automatic power to force the beer up to where it is drawn for use. Air used in this manner requires to be condensed by mechanical power, and, moreover, ferments and otherwise injures the beer. Carbonic acid, on the other hand, not only furnishes spontaneously any required degree of pressure, but adds an important element to the beer itself, supplying any deficiency in effervescence, preserves the beer fresh and sparkling, and enables the contents of each cask to be used, unimpaired in quality, down to the last half pint.

2. *Artificial Mineral Waters.*—For fortifying and recharging natural mineral waters which are deficient in carbonic acid, the natural dioxide gas is usually employed directly at the spring, without condensation to liquid form, and for this purpose it is superior to gas prepared by any artificial method. But for the manufacture of soda and other artificial waters that are made from ordinary or distilled water, the liquid dioxide condensed from natural gas has one defect, *viz.*, it contains a small percentage of atmospheric air, which, when present, prevents the perfect combination of the carbonic acid gas with the water, and inclines the gas to escape too readily when the bottle containing the aerated water is opened. For this sole reason, the principal maker of artificial soda and other sparkling waters in Frankfurt uses carbonic acid gas made by treating magnesite with pure sulphuric acid.

Hydrobromic Acid, Concentrated; Note on. Chas. T. Tyrer. Pharm. J. 1896, 94.

The author states that, owing to the complaint that the concentrated acid of sp. gr. 1.275 has a smell of sulphurous acid, a careful examination of the acid was made, but no sulphur compounds could be detected. A sample of the acid of sp. gr. 1.640 was re-distilled until colourless. It was free from sulphurous acid and bromine, though smelling remarkably like the former. Hydrobromic acid of sp. gr. 1.25 and upwards, attacks glass rapidly, and the silica when once dissolved does not separate out readily on dilution, but only on neutralising the acid. The author concludes that a sp. gr. of 1.25 is the highest concentration possible for a really reliable acid; acids of higher specific gravity rapidly change colour, and contain silica.—A. S.

Hypophosphorous Acid, Note on. Chas. T. Tyrer. Pharm. J. 1896, 94.

THE author considers the method of preparing this acid from its calcium salt (Lunan, "Year Book of Pharmacy," 1888, 21; Cooley's "Cyclopedia," 2, 1273) unsatisfactory, as calcium sulphate or oxalate (according to the acid used as precipitant) dissolves, and gradually separates out.

As potassium tartrate is slightly soluble in dilute alcohol, the same objection arises with the U.S.P. method, which consists in decomposing the potassium salt with tartaric acid and separating the potassium tartrate with alcohol.

He prefers the method of preparation from the barium salt by careful precipitation with sulphuric acid in dilute solution. The acid prepared in this way dissolves a small quantity of BaSO_4 , but nothing separates out, even on long standing; this acid also, when of sp. gr. 1.137, contains 30 per cent. of real hypophosphorous acid.

Concentrated hypophosphorous acid attacks glass and porcelain much more readily than concentrated phosphoric acid, and the separation which sometimes occurs on neutralisation is due to silica.—A. S.

PATENTS.

Production of Bleach and other Products, Improved Means for Treating Sodium Chloride for the. L. Blackwell, Stoke Newington Common, Middlesex. Eng. Pat. 14,122, July 24, 1895.

"EFFION," a liquid resulting from the distillation of animal matters, is mixed with a stated proportion of sodium chloride, "and a solution of 'cupion' and chlorine is, it is alleged, formed by the absorption of the latter by the former. This solution is then poured off, leaving," it is stated, "the sodium remaining in the vessel." The effion solution of chlorine is heated, and the chlorine evolved may be passed over slaked lime to obtain bleaching powder. Carbonic acid may be passed into the mixture of cupion and salt "to liberate chlorine," it is said, and "obtain sodium carbonate."—E. S.

Ammonium Carbonate and Acid Ammonium Carbonate, The Manufacture of from certain Waste or By-Products [Waste Kiln and Blast-Furnace Gases], and Apparatus for Use in such Manufacture. H. R. Lewis, London. Eng. Pat. 14,618, Aug. 1, 1895.

THE waste gases from kilns, blast furnaces, or the like, after passage through water or other cleansing liquid, are forced, with the gases produced in the distillation of gas-liquor, with steam into suitable condensers, where crystalline ammonium salts are formed. A "continuous still" is preferably used in distilling the gas-liquor, to prevent the formation of a solution of ammonium carbonate as a distillate, which is liable to decompose. The residual gases are washed to prevent waste of ammonia. The ammonium salts obtained are exposed to a current of air to remove any sulphide; or they are washed with a little water and dried, thus insuring that any ammonium carbamate present is converted into carbonate, according to the equation $\text{CO}(\text{NH}_2)_2(\text{ONH}_4) + \text{H}_2\text{O} = (\text{NH}_4)_2\text{CO}_3$, and this carbonate is converted into the more stable bicarbonate by contact with carbonic acid in presence of moisture, or by passing air or other gas over it, in the latter case with evolution of ammonia, which is collected.—E. S.

Formates and Nitrites, Impts. in the Preparation or Manufacture of. M. Goldschmidt, Charlottenburg, Germany. Eng. Pat. 17,066, Sept. 12, 1895.

It is known that a formate is produced when carbonic oxide gas is passed over soda (or preferably soda lime) heated to about 230° C., and the inventor finds that the reaction is greatly facilitated by conducting the process under pressure.

To prepare a nitrite, a mixture of a nitrate and formate is heated to fusion. With sodium salts and free alkali, the reaction is represented by the equation—

Instead of first preparing a formate and then using the formate to obtain a nitrite, the latter may be obtained in a single process, by simply passing carbonic oxide over a mixture of a nitrate and corresponding hydroxide, according to the following equation, in which "M" may be sodium or other suitable metal:—

The mixture exposed to the action of the gas is first heated gently until it will absorb no more CO; the gas is then withdrawn, and the temperature raised to the point of incipient fusion of the mixture, under which conditions, the transformation into nitrite takes place quantitatively.—E. S.

Cyanides and other Compounds, Improved Process for the Extraction of, from Illuminating and other Gases. F. Livesey, London. Eng. Pat. 18,334, Oct. 1, 1895.

See under II., page 644.

Sulphurous Acid and other Gases or Fumes, Method of and Apparatus for Washing and Compressing. E. Porak, Riebnberg, Bohemia. Eng. Pat. 12,613, June 9, 1896.

VIII.—GLASS, POTTERY, ENAMELS.

Coloured Pictures, Writing, or the like [Indestructible] on Glass, Porcelain, Enamel, or Sheet Iron; Impts. in or appertaining to the Process for the Production of. F. Albrecht, Liverpool. From W. Kuapp, Hamburg, Germany. Eng. Pat. 2,4283, Dec. 18, 1895.

THE present process is intended as an improvement on Eng. Pat. 13,838 of 1893, and is carried out as follows:—25—35 grms. of pure caustic soda or potash are melted together with 25—35 grms. of lime, 7—13 grms. of sulphate of soda, 3—7 grms. of sulphate of magnesia, and 125—1,000 grms. of water-glass of 38 per cent. "The solution is thoroughly mixed, and may, if desired, be allowed to stand long enough to clear." It is used for printing any device on bottles or other objects of glass, porcelain or enamel, from a rubber plate in relief. The imprint on the bottle is covered with any suitable coloured powder, or powders for the production of several colours, and the bottle with its device is heated to as high a temperature as is feasible. An indestructible label is said to be thus produced.—B. B.

PATENT.

Coating [Insulating] for the Interior of Metal Vessels, Improved. C. F. Hohenberg, Wittstock-in-the-Mark, Germany. Eng. Pat. 12,163, June 3, 1896.

THE surface of the vessel is coated three times with a paste of "permanent white" (BaSO_4) and albumin prepared in the cold, the mixture being coagulated by heat after each addition. The object is to protect, by insulating the metal surface, any articles of food, &c. that may be placed in such vessels from metallic contamination through oxidation; and the composition is stated to be specially useful in the case of aluminium ware.—F. H. L.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Brickwork constructed in Frosty Weather, Durability of. Thonind. Zeit. 1896, 20, 222.

In a series of experiments carried out at Riga it was found that—

1. Brickwork constructed in cold weather, using ordinary mortar prepared with warm water, proved very unsatisfactory in point of resisting power; nor was any improvement effected by dissolving in the water $\frac{1}{2}$ per cent. of calcium chloride.

2. Excellent results were obtained when the mortar was produced with warm water containing in solution $1\frac{3}{4}$ per cent. of common salt.

3. The addition of freshly slaked lime to ordinary mortar, resulted in a satisfactory degree of durability; but still better results were obtained by the exclusive use of freshly slaked lime, especially when employed in conjunction with calcium chloride.

4. An admixture of Portland cement with common mortar increased its resisting power to frost.

5. The best results were obtained with a mixture of Portland cement and 5 parts of sand.—H. T. P.

PATENTS.

Portland Cement, Pigments, and the like: Impts. [Modified Apparatus] in the Manufacture of Finely Pulverised Substances for Use in the Production of. A. Patrick, Glasgow. Eng. Pat. 16,962, Sept. 11, 1895.

THE present patent relates to a device intended to improve the apparatus described in Eng. Pat. 21,292 of 1893. The essential difference consists in the use of a revolving cylindrical sieve with an air blast.—B. B.

Wood, Impts. in the Treatment of [Preserving and Stopping Shrinkage]. A. de Sainte-Marie and A. A. Hoffmann. Eng. Pat. 20,246, Oct. 26, 1895.

THE design of the patented process is to permit "of rapidly stopping the shrinkage which wood slowly undergoes when drying in the air." This result is said to be attained by immersing the wood in a liquid such as solutions of calcium or magnesium chloride, acetates or nitrates of the alkalis, and heavy mineral oils, and raising the temperature of the bath to 100° C. or higher. After treatment for a length of time depending upon the thickness of the boards or blocks, the wood is removed and the salt with which its outer portions are impregnated is removed by washing. Wood may be treated in the manner described in an open vessel or under pressure.—B. B.

Weatherproof Gypsum, Stone or Bricks; Process for the Manufacture of. P. Kleber, Saarbrücken, Germany. Eng. Pat. 13,187, June 15, 1896.

"TEN parts of sifted ashes, potash, and other alkaline carbonates are mixed in the dry state with 1 part of a mixture consisting of 80 parts of gypsum and 20 parts of hydraulic lime." The product is kneaded with "saturated gypsum water acidulated with 5 per cent. of sulphuric acid," and is moulded into bricks, which are dipped into "a saturated solution of alum or other alumina or alum earth which has been acidulated with one-third of sulphuric acid." The resulting blocks are dried, and are said not to effloresce or disintegrate by the action of weather.—B. B.

Peat and other Lignous Substances for Producing Paving Blocks, Slabs, Tiles, Slates, Conduits, and Fuel; New or Improved Process for. R. F. Strong, London. Eng. Pat. 13,649, June 20, 1896.

Dry peat, sawdust, or similar material is ground and mixed with 20—30 per cent. of lime or magnesia, and the mixture is treated with 10 per cent. of pyroligneous acid. The product is pressed into blocks, cooled by a fan, and is then ready for use as paving, either in block form or in powder, applied in the manner adopted for asphalt. For fuel, 1—2 per cent. of lime may be used and 5 per cent. of pyroligneous acid; or a peat coke may be made by adding to the mass, before compression, 3—5 per cent. of silicate of soda in aqueous solution, pressing, and coking.—B. B.

X.—METALLURGY.

Metals (Non-Ferrous), Annual Report on Progress in the Extraction of. C. Schnabel. Chem. Zeit. 1896, 20, 595—599.

Zinc.—In treating zinc ores electrolytically, the main endeavour has been to obtain solid metal, free from slime. So far, however, the process has not been successfully applied to the extraction of zinc from rich ores, although it is used to recover the metal as a by-product from pyrites and argentiferous galena or blende. For the treatment of burnt pyrites, the processes of Höpfner (who converts the zinc into, and electrolyses, the chloride) and v. Kittler are used. For the other ores named, the methods of Ashcroft, Höpfner, Siemens and Halske, and Pape are available; the two former use chloride solutions, the two latter sulphates. The Ashcroft process is in use at Newcastle (N.S.W.) in connection with Broken Hill ore. The ore is roasted and leached with ferric chloride, which gives zinc chloride and ferric hydroxide; on electrolysis of this a compact zinc is deposited, and the solution is regenerated. The residue, containing less than one-third of the original zinc, is smelted for argentiferous lead in blast furnaces, the ferric oxide assisting as a flux for silica. In electrolysis, iron anodes are first used, so that ferrous chloride may be formed, and then carbon anodes are substituted, in order that the liberated chlorine may peroxidise the iron salt. Between the electrodes there is a canvas partition, to prevent the access of iron solution to the cathode, and the zinc liquors are circulated first through the cathode compartment, and then, when nearly freed from zinc, through the iron and carbon anode compartments successively; they are finally returned to the ore-leaching vats. By maintaining a rapid circulation and a higher level of liquid in the cathode chamber than in that containing the anodes, the ferrous liquor is excluded from the former, and the zinc is therefore practically free from co-deposited iron. The metal is re-melted. The electrodes in each bath are placed parallel, but the baths themselves are coupled up in series. The current strength used is 50—55 ampères per sq. m. at 1.1 volt pressure in the baths with iron anodes, and 2.7 volts in the others; and the expenditure of coal under the boilers is equal to from 3 to 4 parts by weight for 1 part of zinc recovered. The chief cost in this process is in the consumption of anode iron, which amounts to 67 parts by weight per 100 parts of zinc. The electrolytic refining of zinc containing lead is practised at Ilseburg; but the extraction of zinc from alloys of zinc, lead, and silver at Hoboken (Antwerp) is diminishing in favour, the distillation of the zinc from the alloy, followed by the separation of the silver and lead, having been found more advantageous. The market for zinc salts is very limited; but the sulphate is made at Julius-hütte, and Sophienhütte (Goslar), by leaching roasted mixtures of galena, blende, and pyrites in rotating iron drums. The conversion of zinc sulphate into oxide has not yet been economically effected.

In the dry way it is well known that blast furnaces yield only a pulverulent deposit of zinc. Biewend's process (Chem. Zeit. 1895, 19, 1357; this Journal, 1895, 663), which consists in heating blende with metallic iron in the blast furnace, tapping out the iron sulphide with the slag, and passing the zinc-bearing gases through a condenser filled with glowing coal, is not likely therefore to yield the metal in a satisfactory

condition. In this process the sulphide of iron is roasted to oxide, and the latter is reduced to the metallic state for use again. No large-scale experiments have as yet been instituted. Lynen's condensing plant, in which several zinc retorts are connected with a single condensing chamber, cooled to 415–550 °C. by means of air-circulating pipes, and with a layer of liquid zinc upon the floor, has not yet come into use. Steger (Preuss. Ministerial Zeits., 1894, 163) substitutes magnesia for clay in the manufacture of retorts, producing vessels which have a higher thermal conductivity and less permeability to zinc vapour. These Frankei retorts, as they are termed, are under trial in Silesia, and the original difficulty, introduced by the susceptibility of the magnesia to changes of temperature, is said to have been successfully met.

Gold.—The Siemens-Halske electrolytic process for the recovery of gold from cyanide liquors is in use by the Rand Central Ore Reduction Co. at Johannesburg, and thereby 70 per cent. of the precious metal in the ore is recovered. The electrolytic separation of gold and silver has been successfully practised at Pittsburgh and St. Louis, U.S.A., and at Pinos Altos in Mexico, and more recently at the Deutsch. Gold- u. Silb.-Schmelzanstalt, Frankfurt-on-Maine.

Silver.—The Rössler-Edelmann process for the desilvering of lead by zinc containing aluminium, followed by electrolysis of the resulting zinc-lead silver alloy has been given up in Lantental in favour of the old process, and is but little employed in Ilobohen. The zinc skimmings of the Parkes process are now distilled in the United States in petroleum-fired retorts. The treatment of argentiferous and auriferous anode slimes, consists usually in obtaining the precious metals in alloy with lead. Where this cannot be done, the slimes are treated in the wet way, and are either—(1) stirred with silver sulphate solution, which causes the copper to dissolve and precipitate an equivalent of silver; or (2) they are digested with dilute sulphuric acid in the presence of air, to oxidise and dissolve copper; or (3) they are boiled with strong sulphuric acid, which dissolves both silver and copper, and leaves the gold untouched; or (4) the slimes are cast into anode plates and treated by electrolysis.

Nickel.—In separating the copper and nickel from rich mattes obtained from the Bessemer converter, the Orford Copper Co. (U.S.A.) remelts the matte in blast furnaces with sodium sulphate and carbon. The resulting sodium sulphide unites with copper and iron sulphides to form a matte that retains but little nickel, the greater portion of that element concentrating in a second matte which, being heavier, is found below the former. Emmens' process of separating copper from nickel mattes by chloridising-roasting is not suitable for material containing much copper, as the extraction of the copper is then incomplete; for example, at Youngwood, U.S.A., a matte containing 20 per cent. of Cu. failed to give up the whole of that amount. Basse and Selve (Chem. Zeit., 1892, 16, 1725) patented a process for electrolysing nickel salts, consisting in adding organic compounds (tartaric or citric acids, glycerin, or dextrose) to maintain the oxides in solution, and then an excess of caustic alkali, electrolysing the bath with a current of 0.3–1.0 ampère per sq. dm. In this way, iron, cobalt, and zinc were deposited at the cathode, whilst the nickel remained dissolved, or partly precipitated as hydroxide, according to the concentration of the bath. Ammonium carbonate was afterwards added to the bath, in quantity sufficient to carbonate the whole of the caustic alkali, and the nickel was then obtained on the cathode by electrolysis.

Copper.—In the roasting of ores in districts where wages are high, furnaces with mechanical stirring are rapidly superseding those which require hand labour; in the United States, besides rotating cylinders with continuous feed, the O'Hara-Brown, the Pearce, the Keller-Gaylord, and the Brown horse-shoe furnaces are largely employed. The electrolytic refining of copper is now greatly facilitated by the use of compressed air, according to the systems of C. and H. Borchers, and Siemens and Halske. The air is introduced under pressure through

lead pipes, terminating in glass jets near the bottom of the vat; by this means arsenic and iron are both precipitated (as arseniate of iron), the liquid is circulated, and the current density may be safely increased from 30–50 to 100 ampères per sq. m. When the electrolyte is saturated with bismuth and antimony, taken up from the anode, it must be removed, and treated with copper oxide or basic copper salts in a separate vessel, a current of air being meanwhile passed through the liquid. After filtration and acidification the liquid is used again. The Hayden process has not been extended in the United States, and the process of Smith and Randolph has but a limited application. In all three processes the raw copper plates must necessarily be of equal thickness, which necessitates costly preparation by rolling and cutting to size; but even then there are irregularities in the plates for which allowance cannot be made. The advantage of the processes consists in the rapidity of the solution and the moderate thickness of the plates, entailing only a comparatively small locking up of capital. In Baltimore, Hayden's process is in use, and by it plates 6.44 mm. thick are treated in 12 days with a current of 160 ampères per sq. m. The three processes have not been used in Europe.

Aluminium.—Bucherer, of Cleveland (Chem. Zeit., 1892, 16, 1764; see also this Journal, 1893, 272), and the Aluminium Industrie Gesellschaft Neuhausen (Chem. Zeit., 1893, 17, 1006) electrolyse aluminium sulphide, either (in the latter process) alone or in a bath of alkaline or alkaline earth chlorides or fluorides, the electrolyte being heated either by the current or by external firing. For an externally-fired bath of the sulphide in sodium or potassium chloride, a current pressure of 2½–3 volts suffices, whilst for the electric heating of the mixture by the electrolysing current, 5 volts are required. The bath is of cast or wrought iron lined with carbon, and the upper part of the vessel is filled with reducing gases. Owing to the comparatively low temperature which suffices for the purpose, neither the carbon anode nor the lining is attacked by the sulphur set free, and the aluminium produced is exceptionally pure. The chief obstacle so far to the use of the process is the high cost of the aluminium sulphide.—W. G. M.

Fibrous Wrought Iron and Crystalline Low Carbon. The Conditions which Cause. W. F. Durpe. J. Franklin Inst., 1896, 142, 110–148.

The difference of structure of wrought iron and ingot iron is not due to the former containing a smaller percentage of carbon, for in many samples the reverse holds good, but to the existence in wrought iron of interstitial slag. Wrought iron of truly fibrous structure may, without suffering molecular alteration, yield a crystalline fracture when subjected to a sudden tensile strain (a jerk), or to a sudden compressive strain (a jar). The appearance of a crystalline fracture is due to the rupture of the material of the test piece in, approximately, a single plane, whereas the same metal ruptured so as to allow the interlocking laminae to slide over each other before severance, exhibits a fibrous fracture. The formation of blowholes in steel ingots probably arises from the entanglement of air in the metal as it is poured into the ingot mould, the distribution of the air thus entangled, being similar to that observed when water flows from a trompe into a receiver already containing water. The more viscous the liquid the more persistent the retention of the bubbles. Water vapour thus entangled in molten steel would yield hydrogen, which gas is actually found in the blowholes of steel ingots. The mean composition of gases from this source is given by Müller as H, 79 per cent., N, 19 per cent., CO, 2 per cent.; the same authority also states that the average pressure was 120 lb. per sq. in. The author calculates that when an ingot containing an average number of blowholes is rolled into a bar, a disruptive stress (due to the reduction of the areas of the cylinders generated by the extension of the blowholes), of 132.7 lb. per sq. in. may be produced. In unfavourable cases this internal stress may rise to as much as 49,545 lb. per sq. in., i.e., to a point above the elastic limit of soft steel. He dissents from the idea that the greater strength of Whitworth "fluid compressed steel" is due to the elimination of blowholes, holding rather that it is to be

ascribed to the forcing of the molecules of the metal into more intimate contact, as in forging. Internal fracture of ingots may occur in reheating, if that operation be rapidly performed, for the expansion of the exterior may set up stresses sufficient to determine rupture of the central portions. The persistence of such cavities in the finished forging causes mechanical weakness, and flaws of this kind are difficult to detect. It is suggested that irregular variation of the electrical resistance of a given bar, tested at different points on its length, might be a means of diagnosis.

—B. B.

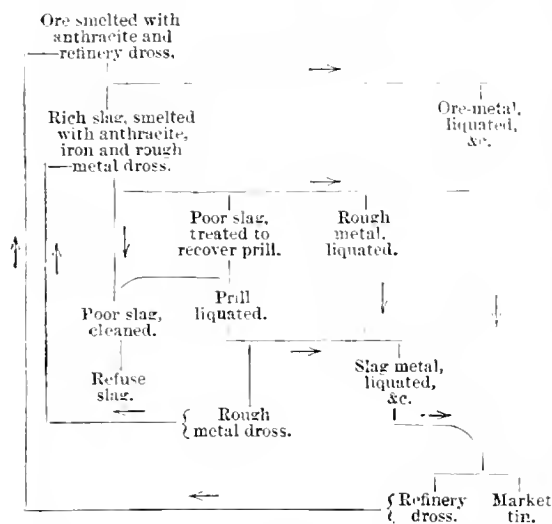

Tin Smelting at Pulo Brani, Singapore. J. McKillop and T. F. Ellis. *Proc. Inst. C.E.* **75**, 60—77.

Tin smelting in the Malay Peninsula has been until recently carried out in a primitive manner by the Chinese. The enactment of regulations for the preservation of forests threatens the Chinese tin smelter with extinction, especially in the face of the fact that European companies are building modern anthracite-smelting works in the district. The present paper contains a full description of one of these works and the process conducted therein, recently started near Singapore. The ore is assayed by the cyanide process, and its value is determined by the appearance and hardness of the button in addition to its actual weight. Great attention is paid to the preparation of the ore before smelting, as it is easier to produce tin of good quality by eliminating the impurities from the ore than by smelting and refining the metal. The chief impurities are mispickel, copper pyrites, and iron pyrites. Wolfram is never entirely absent and causes loss of tin by increasing the richness of the slags. Arsenic, sulphur, or copper render the tin useless, and if an ore contain either of the first two, it is roasted once at least. When roasted, it is sluiced and sorted into three kinds, which are treated in different ways according to their composition.

The metallurgical processes are considered in four parts, viz.:—(A) Smelting ore, with the production of rich slag and ore metal; (B) Smelting rich slag, with the production of poor slag and rough metal; (C) Treatment of poor slag containing tin as prill; and (D) Refining the metal products of A, B, and C.

The scheme of smelting is shown by the following diagram.

DIAGRAM SHOWING THE PROCESSES OF SMELTING.

The recovery of the prill used to be effected by crushing and washing, as practised in Cornwall, but this method is now abandoned and the slag is re-melted to allow the metal to sink and thus separate. The liquation method is employed for refining. The consumption of iron added to the slag charges is 4.7 per cent. of the tin obtained. Welsh anthracite is the best reducing agent but is expensive

at Singapore and it has been found that coal of good quality may replace it. The amount of anthracite required is 17.0 per cent. of the ore but 10.0 per cent. more than this figure must be used if other coal be employed. The coal first tried was Australian, but this has been replaced first by Japanese coal and latterly by that from the Labuan and Tonkin coal-fields. In connection with the smelting a regenerative furnace of the Siemens type was tried, but it proved unsuccessful owing to the impossibility of keeping the chambers free from tin.—A. W.

Alloys of Iron and Antimony. The Density of and the Mean Specific Heat between 0° and 100°. J. Laborde. *Comptes rend.* **123**, (1896) [4], 227.

The alloys were made by melting pure crystallized antimony in a brasqued crucible with iron wire cut into small pieces. When the iron had melted, the alloy was well mixed by agitating the crucible, and poured out into an ingot mould where it cooled rapidly. In the following table, the calculated specific heat is based upon the values obtained for the particular metals used, viz., 0.1136 for the iron and 0.0509 for the antimony.

No. of Alloy.	Iron Per Cent.	Density at 0°.	Specific Heat.	
			Found.	Calculated.
1	18.48	7.211	0.0639	0.0625
2	25.69	7.912	0.0688	0.0670
3	35.42	8.300	0.0753	0.0731
4	39.20	8.071	0.0779	0.0754
5	43.12	8.298	0.0737	0.0778
6	55.02	8.159	0.0869	0.0854
7	61.20	8.120	0.0903	0.0892
8	81.20	7.800	0.1028	0.1019

Almost all the densities are equal to or greater than that of the heavier constituent, iron, showing that a considerable contraction had occurred. At first, the density rapidly increases with the percentage of iron, then it diminishes, but more slowly; the density of the alloy No. 4 is abnormal.

The specific heat in each case exceeds the calculated value, the differences being for the most part greater than the errors of experiment; alloy No. 4 shows the greatest divergence. The composition of this alloy is nearly Fe_3Sb_4 (38 per cent. Fe).

The results in general, accord with the observations of M. Weiss, who showed that the magnetic properties of these alloys increases rapidly when the proportion of iron either exceeds or falls below that corresponding to the alloy Fe_3Sb_4 .—L. A.

Aluminium, Silver, Gold, Copper, and Platinum; Melting Points of. S. W. Holman, R. R. Lawrence, and L. Barr. *Techn. Quarterly*, 1896, **9**, 24—39.

THE metals used in this investigation were extremely pure with the exception of the platinum in which there was $\frac{1}{2}$ per cent. or more of impurity. The melting points were calculated from the measurement of the thermal electromotive force of a couple consisting of one wire of platinum and one of a 10 per cent. rhodo-platinum alloy. One junction was placed in the melting or solidifying metal, the other being surrounded by ice. The battery employed consisted of two Samson-Leclanché cells, and the E.M.F. was measured in microvolts by the Poggendorff null method. For the temperatures required to be known for the equation the authors chose zero and the melting points of sulphur and of pure gold, the recent work of Holborn and Wien being taken as provisionally correct in the case of the latter. The following melting points were obtained in this way:—Aluminium, 660°; silver, 970°; gold, 1072°; copper, 1095°; platinum, 1760°.—C. A. M.

Gold-Arsenic Works at Bovisa, Italy. Eng. and Mining J., Aug. 29, 1896, 201.

THE works at Bovisa (Milan, Italy) belonging to the Società Anonima Ingegneri L. Vogel, are among the most complete of their kind in Europe. The principal

object of the company is the production of mineral superphosphate. The phosphates, amounting to about 75,000 tons yearly, are mostly imported from South Carolina, and about the same quantity of sulphuric acid is produced on the premises for converting the phosphates into superphosphates.

For the production of sulphuric acid about 25 tons per day of iron pyrites are burnt in *Etagen-Oefen*. Of these 25 tons, 15 tons come from the mines of Agordo (Udine), containing from 2 to 3 per cent. of copper, which is saved after roasting by lixiviation. The remaining 10 tons come from the Cuni mine, in the neighbourhood of Mount Rosa.

Worked for free gold since the time of the Romans, this mine constantly gave good returns up to the beginning of this century, when the ore having suddenly become very refractory, the mine was shut down.

In 1887 the mine was leased by the Societa Anonima L. Vogel. The problem was very complex, and the only way to make the concern pay was to utilise all that the ore contained—sulphur, arsenic, and gold. The plan which has been carried out ever since is as follows:—

The ore containing enough iron pyrites to burn by itself in the *Etagen-Oefen* is sorted out and sent to the works at Bovisa (distance, 5 miles by waggon and 65 miles by railroad); the poorer ore is to be treated at the mine with cyanide.

The ore going to Bovisa contains an average of 34 per cent. of sulphur, 10 to 12 per cent. of arsenic, 0.6 to 0.7 oz. of gold, and 2.5 oz. of silver per ton. This ore is subjected to a first roasting in *Etagen-Oefen*, where it is freed from the sulphur and arsenic. Attached to the roasting furnace are two series of large leaden canals through which the sulphurous and arsenious acids are made to pass. The sulphurous acid then goes to the lead chambers to be converted into sulphuric acid; the arsenious acid condenses in the canals in the form of a reddish-white slime.

These slimes are taken out from time to time, dried, in order to be subsequently subjected to a last sublimation so as to obtain a white commercial product 99 per cent. pure. So far no difficulty was met with, but as soon as they began the sublimation in a kind of *Muffel-Ofen* troubles began. The slimes were found to contain some free sulphuric acid and some very fine particles of oxide of iron. Owing to the presence of these two substances it was found impossible to obtain by sublimation a pure product; the arsenious acid obtained had a faint reddish tint; its purity was never more than 90 per cent.; it was not entirely soluble. It was evident that, before trying sublimation, it was absolutely necessary to get rid of the free sulphuric acid present. They devised a large agitator, in which the slimes were agitated with water, which was siphoned off after letting the slimes settle, and the operation was repeated three or four times. This treatment, although long, tedious, and expensive, did not give the wished-for results, although a considerable improvement was shown in the sublimation of the slimes thus treated. After trying a few more schemes unsuccessfully, they at last devised a method which was the simplest of all. They built a large rectangular vat of bricks with a false bottom, and a quartz filter on its top, covered with perforated sheets of lead. The slimes coming from the labyrinth are thrown into this vat, and spread evenly all over the filter; then water is allowed to percolate slowly through the mass; the free sulphuric acid present being thus carried out through the false bottom, and recovered by pumping it back to the lead chambers.

The slimes thus washed gave the most satisfactory results, and one single sublimation gave a most beautifully white product containing 98 to 99 per cent. of pure arsenious acid. It is well known that in England and even at Freiberg two sublimations are necessary to arrive at a commercial product.

Before this industry arose the arsenious acid used in Italy was all shipped from England, but in a year's time they were able to supply all demands in Italy, amounting to about 400 tons a year. The greater part of this product is used in glass manufactures and in tanning leather. The product is sold in Italy at 28 frs. per 100 kilos. (about

3.3 c. per lb.). In this manner the sulphur and the arsenic of the ore is well disposed of.

Attention was then turned to the recovery of the gold contained in the roasted pyrites. This product still contains 1.5 to 2 per cent. of sulphur and about 0.5 per cent. of arsenic; in order to eliminate these substances—injurious to the subsequent operation of chlorination—the roasted pyrites undergoes a second thorough roasting in another *Etagen-Oefen* quite similar to the first one, but provided with a fire-place, where a lively fire is made in order to drive out the last traces of sulphur and arsenic. The pyrites thus dead roasted is cooled and then charged into large wooden rectangular vats, lined with lead, and holding 10 tons each. These tanks are provided with a false bottom, covered with a quartz filter, upon which the mass rests. A weak solution of chloride of lime, together with a weak solution of sulphuric acid, is allowed to percolate slowly through the mass, dissolving and carrying with it the gold, the clear solutions passing through the false bottom to the precipitating tanks. One vat of 10 tons is completely lixiviated and washed out in 3 days.

The extraction of the gold in bullion ranges between 85 and 87 per cent. No attempt is made to save the silver, as it would hardly pay the expenses of extraction. In this manner a mine which, owing to the very refractory nature of the ore, was almost worthless 10 years ago, is now giving a very good profit.—W. G. M.

Gold and Other Metals, Double Sulphides of, or the Action at a red heat of Sulphur upon Gold when Alloyed with other Metals. J. S. MacLaurin, University College, Auckland, New Zealand. Proc. Chem. Soc. 1896, [168], 149.

It is shown that when alloyed with silver, lead, copper, or iron, gold is readily converted into a sulphide by the action of sulphur vapour on the melted alloys. Analyses of the compounds so prepared are given which prove that the gold sulphide has the formula, Au₂S.

Gold and Silver, The relative Weights of dissolved, by Potassium Cyanide solutions from Alloys of these Metals. J. S. MacLaurin. Proc. Chem. Soc. 1896, [168], 149.

The author finds that gold and silver are dissolved by solution of potassium cyanide from an alloy of these metals in the proportions by weight in which they exist in it. He shows that this is the ratio of their atomic volumes.

Tungsten. R. Helmbacker. Eng. and Mining J., Aug. 15, 1896, 153—154.

TUNGSTEN occurs associated with tin ores in the Erzgebirge, especially in the Zinnwald Mines, north of Teplitz. The tin ore and its associated minerals occur (1) in veins in the older granite rock of the district; (2) finely disseminated through the rock between these veins; and (3) in lodes crossing through both the older and the more recent granites. From these mines an average of about 43 tons is annually obtained, which goes chiefly to Germany and to a large tungsten steel works in Styria, at an average price of about 30 florins per 100 kilos.

There are three varieties of the separated ore in the market. 1. A hand-picked ore. 2. A granular ore, wet-crushed and then dressed. 3. A sandy ore which has been subjected to the same treatment. Average analyses show:—

	1.	2.	3.
WO ₃	76.5	75.6	60.1
FeO.....	10.3	9.8	8.1
MnO.....	12.2	12.6	9.6
CaO.....	1.1	0.4	0.9
MgO.....	trace	trace	trace
SiO ₂	trace	3.6	8.4
Residue (rock, gangue)	13.1

The assay of tungstic acid in the wolfram is conducted by heating 3—5 grms. of the ground ore to 110°, fusing in platinum with sodium carbonate, thoroughly

extracting with water, and filtering. Bases are determined in the residue by the usual methods. The filtrate is acidified with hydrochloric acid and boiled, and the precipitate formed, is weighed, after filtration and drying. Any silica is removed by treatment with hydrofluoric acid and any stannic oxide is reduced to metal by fusion with potassium cyanide, and the separated metal dissolved and determined. From these data the amount of pure tungstic anhydride is easily derived.—J. T. D.

Alloys [Al, Ni, Mo, W, and U], New Method for the Preparation of. H. Moissan. *Comptes rend.* 122, 1302—1303.

THE method is based on the powerful affinity of aluminium for oxygen. A mixture of the oxide to be reduced and aluminium filings, is projected into a bath of melted aluminium. The heat which is disengaged by the combustion of a portion of the aluminium by the oxygen of the air is so great that the oxides of the most refractory metals are reduced, whilst the metal itself dissolving in the aluminium, gradually raises the melting point of the alloy. In this way alloys of aluminium with nickel, molybdenum, tungsten, uranium, and titanium have been obtained. In certain cases the heat given out during the reaction is so great that occasionally alloys containing 75 per cent. of tungsten have been maintained in the liquid condition. The reaction is sometimes explosive.

These alloys enable us to introduce the refractory metals, of which the fusing point is higher than the temperature of our ordinary furnaces, into any other metal possessing even a higher melting-point. For example, by introducing metallic chromium into melted copper an alloy containing not more than 0.5 per cent. of chromium is obtained; but melted copper dissolves an alloy of aluminium and chromium in all proportions forming a mixed alloy, copper-chromium-aluminium. From this alloy the aluminium may easily be eliminated by covering the melted bath with a thin layer of copper oxide which dissolves in the copper and oxidises the aluminium to alumina which swims on the surface.

This process might be used for the introduction of tungsten or titanium into a bath of steel kept molten in a Siemens-Martin furnace. The excess of aluminium could then be burnt away or destroyed by the addition of oxide of iron.—J. S.

Platinum in New South Wales. Occurrence of.

Eng. and Mining J. 1896, 62, 126.

PLATINUM mixed with gold has recently been discovered near the newly formed townships of Fifield and Platina. The metals occur in crevices in the bed rock and in the dirt at the bottom, in the form of small, water-worn grains, and are obtained by puddling and washing. The gold is extracted by amalgamation with mercury, leaving behind the crude platinum. An analysis of the latter by the analyst to the mines department gave:—Platinum, 75.90 per cent.; iridium, 1.30 per cent.; rhodium, 1.30 per cent.; palladium, traces; osmiridium, 9.30 per cent.; iron, 10.15 per cent.; copper, 0.41 per cent.; lead, traces; siliceous matter, 1.22 per cent. The ratio of platinum to gold is from 3 to 1 up to 6 to 1.—A. S.

Vanadium, its Alloys and their Applications. M. K. Hélonis. *Bull de la Soc. d'Encouragement*, June, 1896, 904—908.

At a height of about 4,800 m. on the elevated plains of the great chain of the Andes an anthracite mine is worked, containing two parallel, inclined beds of vanadium-containing coal, from 2 to 3 m. thick, and 1,400 m. long. The beds are separated by calcareous deposits. This coal burns readily, leaving 2 per cent. of ash, or 20 kilos. per ton, having an amber colour, and yielding 14 to 25 per cent. of vanadium as tetroxide, a little zirconia, notable traces of platinum, besides about 16 kilos. per ton of silver. The author has devised a process whereby vanadic acid and vanadates may be obtained at small cost from this ash, and anticipates from this source the probability of technical applications, not only in relation to dyeing, but to metallurgy.

Vanadic acid is reduced by aluminium at a red heat by successive stages to V_2O_3 ; but reduction to metal requires a temperature of about $1,700^\circ \text{C}$., when the evolution of heat from the formation of the alloy is liable, without certain precautions, to give rise to violent explosions, the light given out being comparable to that of the electric arc. Alloys may be obtained containing from 1 to 40 per cent. of vanadium, out of which the aluminium may be dissolved, leaving the vanadium in powder or in brilliant scales, which latter are not attacked by HCl or alkalis, and scarcely by concentrated sulphuric acid, but dissolve in nitric acid with production of vanadic acid, and, when thrown on a red-hot plate they inflame with projection of brilliant sparks.

The author has observed that the Swedish iron, from the magnetic oxide of Mount Taberg, so remarkable for its ductility, contains vanadium; and also that certain slags from Staffordshire iron furnaces, producing very ductile iron, contain a considerable proportion of vanadic acid. For application in the metallurgy of iron, alloys of vanadium are obtained by reduction of the oxides by aluminium in powder, the alloys named being aluminium-vanadium, iron-aluminium-vanadium, iron-nickel vanadium, and iron-chromium-vanadium. Alloys of copper-aluminium-vanadium have also been obtained for experiments with bronze. There is a special alloy of V-Al, remarkable for its sonorous quality, applicable in making bells and certain musical instruments.

A specimen of dephosphorised steel, tested after being melted in a plumbago crucible, gave breaking charge, 96 kilos. per sq. mm.; elongation, 2.3 per cent. The same, similarly melted with 1 per cent. of vanadium, gave breaking charge, 109 kilos.; elongation, 7.53 per cent.; limit of elasticity, 78.7. A second experiment was made, a magnesia-lined crucible being used, and 0.5 per cent. of vanadium added, which gave on trial, breaking charge, 66 kilos.; elongation, 16 per cent. A third experiment, using a magnesia-lined crucible, but adding 1 per cent. of vanadium, gave an alloy having breaking charge, 97 kilos.; elongation, 14 per cent. The same forging, annealed, gave breaking charge, 71 kilos.; elongation, 20 per cent. This last specimen, though very soft, took a remarkably high temper. A specimen of soft iron, with resistance, 38—39 kilos., and elongation, 19 per cent., after fusion with iron-vanadium equal to 0.5 per cent. of vanadium, gave a bar forged without annealing, having breaking charge, 61.25 kilos., and elongation, 12 per cent., which, after annealing, became respectively 53 kilos. and 32 per cent. elongation. This last specimen showed very great malleability and ductility. An aluminium-bronze was also tested, containing 8 and 1 per cent. respectively of aluminium and vanadium, which gave breaking charge, 71 kilos.; elongation, 12.5 per cent.

Nickel oxide is reduced by aluminium powder, and nickel-aluminium alloys containing from 25 to 90 per cent. of nickel, have been obtained. Aluminium added to fused commercial nickel instantly reduces the oxide present with a strong reaction. Nickel, chromium, tungsten, and molybdenum are easily extracted from their alloys with aluminium, and nickel thus obtained becomes pyrophoric at over 100°C . Great care is necessary in preparing molybdenum-aluminium, since a mixture of molybdenum oxide and aluminium powder, when strongly heated, explodes with a report like a gun-shot and projection of the metal. Iron-molybdenum may be prepared without danger. An alloy containing 21 per cent. of molybdenum is described as being hard enough to scratch glass. Steel, melted with 0.5 per cent. of molybdenum, acquires extraordinary hardness. —E. S.

PATENTS.

Compound Metal Sheets or Plates, Impts. in the Manufacture of, for Use in Making Silvered Copper Utensils and other Articles. O. Inray, London. From E. Martin, Paris. Eng. Pat. 11,763, June 17, 1895.

Pure copper, or a special alloy of 98 parts of copper, 1·9 of tin, and 0·1 of nickel is cast into ingots, which are slightly hammered while hot. The surface is then planed, coated with the double nitrate of silver and mercury, and finally with a plate of silver, which is fixed by pressure. It is then enclosed in a sheet of copper and secured with a thin copper hoop. The ingot thus prepared is heated to 700° or 800° C. and rapidly rolled into a bar, reheated, and rolled into a sheet. Instead of silver an alloy of silver and aluminium may be used.—J. H. C.

Volatilisation of Galena into White Compounds of Lead, and of Zinc into White Compounds of Zinc, the Making of Litharge, and the Smelting of Metals from their Ores or Slags; Impts. in the Process for. A. C. J. Charlier, Glasgow. Eng. Pat. 14,166, July 23, 1895.

See under XIII. A., page 662.

Metallic Sands and Pulverised Ores [in Blocks with dried Peat], Impt. in the Reduction of. A. A. Dickson, Toronto. Eng. Pat. 12,455, June 27, 1895.

Dried peat is disintegrated between rollers, intimately mixed with the metallic sand or pulverised ore in equal or other convenient proportions, and pressed into blocks, which are then ready for the reducing furnace, either with or without previous charring.—J. H. C.

Zinc-Bearing Ores, Impts. in the Treatment of, and Zinc-Bearing Products. E. A. Ashcroft, Broken Hill, Australia. Eng. Pat. 13,534, July 13, 1895.

This patent relates to the extraction of zinc from its roasted ores by leaching with a ferric salt solution, whereby the iron is replaced by zinc, and subjecting the solution to double electrolysis, by which the metallic zinc is deposited and the leaching solution regenerated, as described in a previous patent (this Journal, 1894, 957). The improvements refer, firstly, to the composition of the working solutions, which are now mixed with a sulphate or chloride of an alkali or magnesium; secondly, to the method of performing the double electrolysis; and thirdly, to the method of performing the leaching operation. The cycle of operations is now as follows:—Leaching, whereby iron is thrown out of solution and zinc substituted; circulation past the cathodes in the zinc electro-depositing plant, where the excess of zinc is taken out; circulation past the iron anodes, where ferrous salts are imparted to the solution; and circulation past the carbon anodes, where the ferrous salts are oxidised to ferric, and the solution thereby regenerated for further leaching. In place of the carbon anodes in the last operation, the oxidation may be effected by chlorine or any other suitable agent.—A. W.

Precious Metals [Gold and Silver], Extraction of, from their Ores and Compounds. Improved Process. W. H. James, London. Eng. Pat. 15,656, Aug. 20, 1895.

The improvement consists in the use of a solution of peroxide of hydrogen in conjunction with potassium cyanide as a solvent.—J. H. C.

Aluminium and Magnesium, Manufacture or Production of Granulated. W. L. Wise, London. From the Aluminium Industrie-Actien-Gesellschaft of Neuhausen. Eng. Pat. 15,959, Aug. 24, 1895.

The metals are heated to a temperature of about 100° C. below their melting points, and then crushed by grinding or stamping while still hot.—J. H. C.

Aluminium, Alloys of [Tungsten and Magnesium]. H. Partin, Paris. Eng. Pat. 21,575, Nov. 13, 1895.

To alloy aluminium with tungsten, a preliminary alloy is made to overcome the difference of their fusing points. It is prepared by first melting together copper, tin, and a little arseniate of potash, then powdering this material, fusing it with tungsten and antimony, and finally adding the metal so produced, to the fused aluminium, in the proportion of from 4 to 10 per cent., according to the tenacity or the sonorousness required. Magnesium may be used in a somewhat similar manner in place of the tungsten and antimony. Increased tenacity is conferred thus upon the aluminium.—A. W.

Metallic and other [Al, Mg, Ca, Sr, Ba, &c.] Compounds, Process for Producing, Decomposing, Converting, Transforming, and Reducing. H. S. Blackmore, Mount Vernon, U.S.A. Eng. Pat. 23,707, Dec. 10, 1895.

THE chief object of this invention is the economical production, from infusible or semi-fusible natural products, of purified chemical compounds or metals, and particularly of sulphides of such metals, as aluminium, magnesium, calcium, strontium, barium, &c., or the metals themselves. The following processes are claimed:—

Fluo-carbides are produced by exposing carbon and a metallic fluoride in a heated state to the action of a volatile element such as sulphur, tellurium, selenium, &c.

Compounds of carbon and fluorine with other elements are produced by passing the vapour of such elements over a mixture of carbon and metallic fluoride (such as lead fluoride) in a heated state.

Sulphur fluo-carbide is produced by passing the vapour of sulphur over a heated mixture of carbon and a metallic fluoride.

Silicon is eliminated from a molten bath or compound by exposing the same to the action of fluorine carbide or sulphur fluo-carbide.

Metallic oxides or infusible bodies to be transformed, are dissolved or suspended in the bath and similarly treated.

Aluminium or other sulphide is produced by exposing the molten or liquefied oxides to the action of carbon bisulphide vapour or of carbon and sulphur.

Cyanides are produced by suspending a metallic carbide in the bath, and exposing it to the action of nitrogen; alkaline cyanides are produced by suspending carbide of iron in a molten bath of alkali sulphide, and introducing nitrogen gas.

Alkali salts are produced from natural products, such as sodium chloride, by suspending alumina in a molten bath of the said natural product, and exposing it to the alternate action of steam and gaseous acid.

Alkali carbonate is similarly produced by using a bath of alkali chloride and subjecting the same to the action of super-heated steam and carbonic anhydride.

Ultramarine is produced by dissolving kaolin or felspar in the bath, and exposing it to the action of carbon bisulphide vapour.

Metals are reduced from their salts or combinations by dissolving them in the bath, and gradually exposing it to the action of highly heated or molten reducing agents.

Aluminium or other metals are produced by dissolving their compounds in the bath, and gradually introducing, in small streams, metallic iron or copper or other reducing agent in a highly heated or molten state, or by slowly commingling said compounds in a molten or dissolved state with a highly heated or molten reducing agent of greater specific gravity, or by exposing the molten or suspended oxides to the alternate action of a non-metallic carbide and a highly heated or molten reducing agent of greater specific gravity, or of a non-metallic carbide and a molten compound (such as potassium cyanide).

Aluminium is produced from bauxite by dissolving it in a molten bath, and heating it as above.

Alkali aluminate and hydrochloric acid are produced by exposing alumina dissolved or suspended in molten alkali chloride to the action of steam.

For any of the above processes a molten flux or bath consisting of a mixture of fluorides and sulphides of the alkali metals, potassium and sodium, may be employed, and the various reactions may be effected in any order.

—J. H. C.

Metallic Alloys, Impts. in the Manufacture of [Cu, Ni, Fe, Co, My, and Spelter]. C. Parnacott, London. Eng. Pat. 23,950, Dec. 13, 1895.

THE proportions are :—copper, 44 ; nickel, 20 ; spelter, 25 ; iron, 7 ; cobalt, 3 ; and magnesium, 1 part. The nickel is first melted and the magnesium added in minute charges, whilst stirring with plumbago rods, after which an equal quantity of copper is mixed in. In another crucible the remainder of the copper is melted with the iron and cobalt, and when properly fused this alloy is poured into the first mixture. The zinc is then added whilst stirring with a charred wooden rod. This alloy will resist oxidation, polish brilliantly and withstand the corroding action of hydrochloric acid in sea water and of all atmospheric influences.

—A. W.

Crucible Melting Furnaces, Impts. in. W. Kirkham, Sheffield. Eng. Pat. 1303, Jan. 18, 1896.

INSTEAD of the usual rectangular fire-brick chamber, a perforated metallic casing of oval form is placed over each fire-grate. This is constructed in segments, secured by straps and bolts to allow for expansion and contraction, and lined with special silica fire-bricks moulded in segments and so arranged and covered in as to form spaces for the circulation of air around such casing. Shutters and dampers are provided for the regulation of the air circulation while the furnace is at work, and for the exclusion of air when it is idle.—J. H. C.

Sulphuret of Aluminium, a Process for the Manufacture of Double Compounds of with other Metallic Sulphides. D. A. Peniakoff, Huy, Belgium. Eng. Pat. 7273, April 4, 1896.

ALUMINIUM free from moisture is mixed with metallic salts rich in oxygen (such as sulphates, phosphates, chromates, or manganates), and then treated with sulph-oxy-carbon or sulphuretted carbon vapours in tightly closed retorts heated to a suitable temperature.—J. H. C.

Smelting Fine Ores, Improved Method for Using Mine Dust [Bricks or Briquettes] of Iron from Calcining Kilns or Hearths. G. Fisher, Shotts. Eng. Pat. 8558, April 23, 1896.

THE dust or residue is pugged, ground, or mixed as in preparing clay for brick-making, alumina or other binding material being added when necessary. The plastic mixture is then formed into lumps and dried ; these, when necessary, are afterwards calcined.—J. H. C.

Annealing Sheet Metal, New or Improved Method of and Apparatus for. W. E. Harris, Ohio, U.S.A. By W. P. Thomson, Liverpool. Eng. Pat. 9552, May 5, 1896.

THE sheets, after annealing and cold rolling, are stacked in an annealing box, with interposed layers of copper filings and pulverised soapstone, and then annealed a second time. Powdered iron ore is in some instances added to the soapstone. Any convenient form of annealing furnace may be employed.—J. H. C.

Amalgamating Machines, Improved Process [Use of Kerosene] for Preventing the Sickening of Mercury in. J. T. Penny, Adelaide, and J. Dungey, South Melbourne, Australia. Eng. Pat. 12,519, June 8, 1896.

THE sickening of mercury is prevented by supplying kerosene in small quantities either to the material under treatment, or at short intervals, to the amalgamating plates and mercury in the machines when at work.—A. W.

Articles of Steel and Malleable Iron, Impts. in Annealing. W. H. Trengrove, Christchurch, New Zealand. Eng. Pat. 13,476, June 18, 1896.

THE articles are enveloped in asbestos before they are placed in the annealing furnace.—J. H. C.

Metallic Alloys [of Al, Cu, Sn, Zn, and Pb], Impts. in and in the Manufacture of. A. P. Cothias, Ivry-sur-Seine, France. Eng. Pat. 14,479, June 30, 1896.

THE improved alloys are composed of copper, tin, zinc, and aluminium, or lead, in the following proportions, or nearly so :—

	No. 1.	No. 2.	No. 3.	No. 4.	No. 5.
Al	10	230	400	880
Cu	160	180	80	40	40
Sn	50	150	190	200	80
Zn	750	660	500	520	..
Pb	10
	1,000	1,000	1,000	1,000	1,000

Ocasionally small quantities of titanium, manganese, tungsten, and the like, in the form of salts, are added to increase the hardness. These alloys have considerable tensile resistance, and may be soldered and worked with the greatest facility.

In preparing the alloys, the desired quantities of copper and tin are first melted together and allowed to cool. The zinc is then added and the whole remelted. The mass is then allowed to cool until it is in a pasty condition, when the aluminium is added, after which the whole is heated to a very high temperature. One-tenth of one per cent. of ammonium chloride and a small quantity of phosphorus are added in the course of the last heating. The phosphorus may be employed in the form of a salt.—J. H. C.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A.)—ELECTRO-CHEMISTRY.

PATENTS.

Electrodes, Impts. in [Carbon Electrodes]. C. Hoepfner, Giessen, Germany. Eng. Pat. 17,505, Sept. 19, 1895.

THE electrodes consist of plates of artificial carbon, in which are embedded projecting pieces of retort or other natural resistant carbon, so as to increase the surface of the electrode, and protect the artificial carbon from the action of the current. The pieces of retort carbon may be fixed in the prepared plates, either before or after they are baked, and the surface of the ground plate may be coated with paraffin, so that the acting surface of the electrode is supplied by the projecting retort carbon alone. It is claimed that by this method of manufacture, plates of any desired size may be made, which have the resistant properties of retort carbon.—G. H. R.

Accumulators, Active Material for Electric [Organic Acid Paste]. F. Dannert, H. Windolf, and J. Zacharias, Berlin, Germany. Eng. Pat. 22,505, Nov. 25, 1895.

THE active material for the plates is prepared by mixing into a paste with a solution of formic acid (CH_2O_2) or tartaric acid ($\text{C}_4\text{H}_6\text{O}_6$) a powder composed of a mixture of a metal and its oxide (say lead oxide). To this paste may be added some jelly, glue, sugar, or substances convertible into sugar. This mixture is placed in the moist state in the electrode frames, and formed after drying.—G. H. R.

Carbon Anodes, Impts. in the Manufacture of, for Electrolytical Processes [Preserving Anodes by Wax or Grease]. P. Jensen, London. From H. Cappelen and D. Cappelen, Skien, Norway. Eng. Pat. 13,521, June 18, 1896.

TO prevent the destruction of the anodes, the carbon of which they are composed is dipped in molten paraffin wax,

or similar inert fatty substance, which enters the pores and solidifies on cooling. The carbon may be impregnated either before or after it has been shaped, and it is claimed that the treatment allows of the employment of inferior carbon and of higher current density.—G. H. R.

XII.—FATS, OILS, AND SOAP.

Oleaginous Seeds (I'Sano, Mohamba, Wild Olive). Note on the Composition of. A. Hébert. Bull. Soc. Chim. (3). 15—16, [15], 935—941.

I'Sano or Unguoko.—These seeds are derived from a large tree of the Oleaceae family, growing in the French Congo territories. The fruit is a drupe of some 3 cm. in length, and encloses a brownish oval nut 2.7×2.4 cm., almost completely filled by the kernel, 37 per cent. of which is shell. The ground and dried seed contains 7.3 per cent. of moisture, and yields 60 per cent. of oil; the residue (oil-cake) contains 33.12 per cent. of total nitrogenous matters (= 5.3 per cent. N), 1.5 per cent. of sugars, 24.37 per cent. of soluble gums, 6.7 per cent. of cellulose, and 4.25 per cent. of ash (chiefly CO_2 , P_2O_5 , salts of Fe, Al, Mg, and K, with a small proportion of sulphates, chlorides, and salts of Ca and Na), and should make a suitable cattle food. The oil is liquid, even at -15°C ., reddish in colour, of insipid flavour, and fishy smell. It is viscous and very siccativ, has a sp. gr. of 0.973 at 23°C ., is but slightly soluble in 90° alcohol, and gives the following reactions:—

Thermal test with sulphuric acid + 117°C .

Nitric acid and mercury: Viscous reddish turgid mass.

Potassium hydrate (sp. gr. 1.34) in the cold: Yellowish-brown coloration.

Potassium hydrate (sp. gr. 1.34) in the warm: Soft, dark-brown soap.

Fuming nitric acid: Brown zone, followed by very energetic reaction, resulting in a carbonaceous mass.

Sulphuric acid: Black coloration, carbonised mass.

When treated with boiling water in presence of litharge, the oil becomes pasty after awhile.

The oil yields 80 per cent. of brown liquid fatty acids, which from the behaviour of their lead salts are unsaturated, and consist of oleic acid (15 per cent.) linoleic acid (75 per cent.), and 10 per cent. of a new solid white acid (named by the author isanic acid), turning directly to rose colour in contact with air; the bromine absorption is double that of oleic acid. The glycerin in the mother-liquor amounts to from 12 to 13 per cent.

It is considered that this oil might be advantageously extracted on an industrial scale, and employed for the same purposes as linseed oil.

Mohamba.—These seeds are very similar to those just described, and contain 8.6 per cent. of moisture when dried at 100°C ., but yield only 12 per cent. (of the shelled kernel) of oil. The oil-cake contains 19.5 per cent. of nitrogenous matter (= 3.12 per cent. N), 1.5 per cent. of sugars, 15.55 per cent. of cellulose, 43.33 per cent. of soluble gums, starch, &c., and 3.05 per cent. of ash (containing the same substances as I'Sano-seed), and forms a nutritive foodstuff.

The oil is liquid at -15°C ., yellow, fairly fluid, inodorous, insipid, only slightly soluble in 90° alcohol, and has a specific gravity of 0.915 at 23°C . The thermal test gives + 55°C .; the nitric acid and mercury reaction results in a yellow turgid mass, becoming pasty after awhile; in the cold, potassium hydrate gives a yellow coloration, and a soft brown soap in the warm; fuming nitric acid produced a brisk reaction, and sulphuric acid a deep brown coloration. Treatment with boiling water and litharge results in the formation of a solid paste. The fatty acid obtained amounts to 90 per cent. of brown, liquid, unsaturated acid, which, when recovered from its lead salt, deposits in time a white fatty acid, soluble in alkali, alcohol, and ether, crystallising from the latter in laminae, which melt at $34-35^\circ\text{C}$. This acid absorbs bromine to the same degree as oleic acid, and therefore seems to belong to the $\text{C}_{18}\text{H}_{32}\text{O}_2$ series, but does not correspond with any known acid; the quantity obtained was too small to permit

of thorough examination. The liquid acid answers to the bromine absorption and elaidin reactions for oleic acid. About 9 per cent. of glycerin is present in the mother-liquor from the saponification of the oil.

Wild Olive.—The seed is derived from a wild olive of the Simaruba variety, found native near Gatira (San Salvador Republic). The drupe is edible, of a sweet but astringent flavour, and contains a seed composed of large plano-convex cotyledons with short, superior radicle, rich in an oil which is used for making soap. The shell amounts to 61 per cent. of the whole seed. The oil-cake is fairly nitrogenous, very bitter in flavour, and contains no starch, but a large proportion of tannin and glucose. On extraction, the seed yields a solid yellow fat (quantity not stated) melting at 30°C ., which contains over 90 per cent. of solid white fatty acids, melting at $48^\circ-49^\circ\text{C}$., and consists of equal quantities of saturated and unsaturated acids. The former, as a whole, melted at $54^\circ-55^\circ$, but the melting points of the three fractions obtained by the acid of barium chloride were respectively $58^\circ-59^\circ$, 44° , and 38°C . The unsaturated (liquid) fatty acids in time deposited a solid white acid, melting at $44^\circ-45^\circ\text{C}$., and probably consisting of saturated acids.—C. S.

Isanic Acid: A New Unsaturated Fatty Acid. A. Hébert. Bull. Soc. Chim. 1896, 15—16, [15], 941—945.

This acid is obtained by fractional precipitation of the fatty acids in I'Sano seed oil (see previous abstract), and, when purified by recrystallisation from ether, consists of foliated crystals, melting at 41°C ., and readily soluble in strong alcohol, ether, chloroform, benzene, acetone, methyl alcohol, and petroleum spirit. With alkalis it forms crystallisable salts. It possesses a particular odour, which it imparts to the seed, and is extremely susceptible to change, turning rose-red on exposure to air, the tinge deepening in proportion as oxygen is absorbed. This colouring matter may be separated by dissolving the acid in ether. The potassium, ammonium, lead, barium, and silver salts are also very unstable, this peculiarity increasing the difficulty of analysing the acid. The mean percentage composition, derived from four analyses, is: carbon, 76.63; hydrogen, 9.30; oxygen, 14.07, which, together with the estimation of the bases in the silver (31.05) and barium (24.40) salts, appears to coincide most nearly with the formula $\text{C}_n\text{H}_{2n-8}\text{O}_2$, n being equal to 14—a view confirmed by the cryoscopic determination of the molecular weight (217). It was, however, found impossible to verify this by hydrogenation with hydrogen iodide (Arnaud's method), nothing but products of advanced decomposition, with traces of a liquid fatty acid, resulting. The authors sought to verify the general formula of their acid by treatment with bromine. The capacity of absorption corresponded appreciably to two molecules. The chlorinated and brominated compounds are unstable, decomposing with loss of the halogen acids.

The ammonium salt is soluble in water, recrystallising as naereous spangles, which turn rose, then blue, on exposure to air. The barium salt is a white powder, soluble in warm chloroform or alcohol, but separating out on cooling in the form of microscopic crystals, which also become rose-coloured in air; and the silver salt is very susceptible to light and air. The red colouring matter may be isolated by solution in sulphuric acid and reprecipitation by water. Experiments with a view to ascertaining whether the formation of this body affords an insight into the general system of the production of vegetable colours, are in progress.—C. S.

Solidifying Point of Mineral Oils. Alteration of. D. Holde. Mitt. Königl. techn. Versuchs. zu Berlin, 1896, 113—116.

The author has shown (Mitt. Königl. techn. Versuchs. 1895, 253; this Journal, 1896, 138) that certain dark mineral lubricating oils suffer a change in their solidifying points by previous heating. Thus, heating to 50°C . may cause an oil normally not solidifying at -15°C . to become gelatinous and non-mobile at that temperature. This observation has now been extended to numerous other samples, and appears to hold generally. Occasionally the

alteration takes place in the reverse direction—that is, a previously heated oil will solidify less readily than the same oil which has not been thus treated.—B. B.

Tung Oil (Chinese Wood Oil). W. H. Deering. Imp. Instit. Journal, Scient. and Tech. Research Dept., Aug. 1896, 303.

This is a glyceride oil giving on saponification 96½ per cent. of fatty acids, which, at ordinary temperatures, are hard and crystalline; it requires 1.18 per cent. of caustic potash for neutralisation and 19.12 per cent. for total saponification. The bromine absorption is 98 per cent. It is a golden-yellow, clear, viscous oil; when exposed to air in a thin film it dries to a white, opaque, solid film in 20 hours, raw linseed oil usually requiring 60 hours. Heated to 500° F., with or without oxides of lead and air stream, it jellified in about 10 minutes, the rapid change being probably due to polymerisation rather than to oxidation. Tung oil will probably be valuable in the manufacture of linoleum.—A. C. W.

Rapinic Acid. J. Zellner. Monatsh. f. Chem. 1896, 17, 309–313.

ACCORDING to Reimer and Will (Ber. 20, 2385), rapinic acid possesses the formula $C_{18}H_{34}O_2$, and is isomeric with ricinoleic acid.

The author, however, has carefully investigated the acid and its zinc salt with a view of obtaining further information regarding the supposed presence of the third oxygen atom, and has arrived at the conclusion that its formula ought to be $C_{18}H_{32}O_3$, or that only two oxygen atoms are present in the molecule; and that although it possesses the latter formula, it is not identical with oleic acid, as it does not exhibit the elaidin reaction.—J. S.

PATENTS.

Soap, Shave Dips, Hop Washes, and the like, Impts. in the Manufacture of [with Soluble Sulphur]. F. W. Saatmann, Driffield. Eng. Pat. 15,568, Aug. 19, 1895.

To obviate the formation of sulphides in the production of soluble sulphur in soaps and the like, the patentee mixes ground resin with about 30 per cent. of flowers of sulphur, heats the mixture to about 120° C., and distils the clear upper liquid at "a temperature exceeding 23° C." The resulting product is readily saponified, and the soap dip or wash so obtained contains the sulphur in a soluble form.

Effluent Waters of Wool-washing Machines, and the like, New or Improved Method of and Apparatus for Removing Fatty Matters from the. [Separation by Air-Blast Agitation.] J. Holmes, Bradford; H. E. Tankard and W. Seafie, Laisterdyke. Eng. Pat. 18,239, Sept. 30, 1895.

See under V., page 648.

Soaps and Saponaceous Compounds [Admixture with Boric Compounds], Impts. in the Manufacture of. J. Ascough, Stafford. Eng. Pat. 10,681, May 18, 1896.

The object of this invention is to increase the antiseptic properties of soaps by the addition of boron compounds in

such a manner that the tendency of the latter to dissociate is avoided. For hard soaps for household or toilet purposes, the following mixture is employed:—Boric acid in powder, 62 lb.; dry sodium carbonate, 27 lb.; boiling water, 44 lb.; tincal borate in powder, 5 lb. These are heated in the boiling pan and stirred until effervescence has nearly ceased; 2 lb. of this boron compound, while still hot and fluid, are stirred into each cwt. of the boiling soap, which is then allowed to set in the usual manner. For soap powders and similar compounds, the boron mixture is allowed to cool until more or less solid before being transferred to the grinding apparatus with the respective substances.

For mineral and polishing soaps the mixture consists of sodium carbonate, dry, 27 lb., and water (boiling), 41 lb.; or soda crystals, 71 lb., with boric acid in fine powder, 50 lb., and calcium borate in fine powder, 16 lb. These are combined in the boiling pan and added to the soap in the manner described above.—C. A. M.

Glycerin and Caustic Soda from Soap Lyes [Electrolysis] Impts. in the Production of. J. Glatz and O. Lugo, New York. Eng. Pat. 10,837, May 19, 1896.

The soap lye left in the manufacture of soap, containing free alkali, sodium or potassium hydrate, fatty glycerides, free glycerin, and some fatty acids, is subjected to the action of an electric current, the anode being composed of zinc or carbon, preferably the latter, retained in contact with the liquor under treatment, whilst the cathode is separated from the anode by a porous partition. It is claimed that in an apparatus constructed on this principle, the current decomposes the caustic soda in the lye, the liberated sodium being attracted to the cathode and immediately oxidised to sodium hydrate. The glycerin compounds are decomposed and the glycerin set free, whilst the albuminoid and colouring matters are rendered insoluble and are readily removed by filtration. The colour of the lye is changed from a dark-brown to a light straw colour. After the electrolytic treatment the insoluble matter is separated from the liquor and the latter distilled. The glycerin obtained is perfectly pure and free from discoloration, and can be used for all purposes in the arts. The caustic soda produced is practically pure, and can be used at once by the soap-maker, since by the above process it is possible to produce a solution of the required density.—C. A. M.

Soap or Cleansing Agent [Mixed with Sawdust], Improved. H. W. Wilson, Todmorden. Eng. Pat. 12,953, June 12, 1896.

In this patent, soap is mixed with sawdust in about equal proportions, the object being to give a certain amount of roughness which will not injure a smooth surface. A secondary advantage is that the soap will float.—C. A. M.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(4.)—PIGMENTS, PAINTS.

PATENTS.

Paints and Pigments [Arsenic Trisulphide and Sulphur], Impts. in the Manufacture of. S. B. Schryver, London. Eng. Pat. 13,973, July 23, 1895.

THE basis of this paint consists of arsenic trisulphide mixed with sulphur. It is prepared by slaking 56 lb. of lime in 100 gallons of water, adding 160 lb. of sulphur, and boiling with wet steam till the liquid is nearly clear. The solution is decanted, 198 lb. of white arsenic added, and the whole again boiled until the pigment reaches its maximum of brightness, when it is allowed to cool, and hydrochloric acid is run in to faint acidity. Other pigments, such as Prussian blue, may be precipitated with the arsenic, if desired, so as to form a green. The material is claimed to be specially suitable for ships' bottoms, owing to the "anti-fouling" nature of the arsenic sulphide. For this purpose it may be suspended in boiled oil and petroleum spirit, and mixed with the oxides of iron and zinc together with lime and rosin.—F. H. L.

Volatilisation of Galena into White Compounds of Lead, and of Zinc into White Compounds of Zinc, the Making of Litharge, and the Smelting of Metals from their Ores or Slags; Impts. in the Process for. A. C. J. Charlier, Glasgow. Eng. Pat. 14,166, July 25, 1895.

This invention consists "in the use of gas under pressure in conjunction with heated air for the conversion of galena into white compounds of lead by volatilisation, likewise the same from zinc ores into white compounds of zinc; also the extraction of all kinds of metals, lead, zinc, iron, antimony, &c., either from their ores, slags, or residues." When working on lead the furnace is built of iron, water-jacketed half-way up. Half of the bottom is made to slope to a saucer-shaped receptacle placed in the other half, and the hot gas and air are led in midway, and just where the slope begins. By the use of gaseous fuel, the formation of slags in the furnace is avoided, and as the waste gases leave the apparatus still under pressure, fans, &c. are not required to drive the fume through the usual condensers. The basin serves to collect any metal that is not volatilised, whence it may be removed without stopping the operation.

—F. H. L.

Protecting Ships' Bottoms against Fouling, Preserving Wood, and Shielding Submarine Electric Cables from Penetration by Tereido Worms; Impts. in Compositions for [Metallic Cresylates]. W. G. Gunn, Bristol. Eng. Pat. 17,871, Sept. 24, 1895.

The essential point of this patent lies in the use of the "cresylate" of either mercury, lead, copper, iron, or zinc. 100 parts of cresol are heated between 80° and 120° C. with 120 parts of the oxide of one of the above metals, or a mixture of them, until a drop of the substance solidifies on cooling. If the composition is to be employed for preserving wood, the cresylate is dissolved in creosote oil, &c., but if a paint is required, it is ground into an ordinary linseed-oil vehicle.—F. H. L.

White Lead, Substitute for [Lead Oxychlorocarbonate], and of other Oxy-Salts of Lead from Lead Sulphate and Lead Chloride; Impts. in the Production of a. S. Ganelin, Philadelphia, U.S.A. Eng. Pat. 8981, April 28, 1896.

This specification describes various processes for preparing different oxy-salts of lead from the chloride or sulphate, one of which, the oxychlorocarbonate, is a new compound, and may be used as a substitute for white lead. (1.) On mixing the sulphate or chloride of lead with magnesia in presence of water, the basic salt $PbO \cdot PbSO_4$ or $PbO \cdot PbCl_2$ is definitely formed, irrespective of the proportions of the substances present. (2.) By treating lead sulphate with half its equivalent of a stronger base in presence of water and a salt of the desired radical, an oxy-salt of lead is produced in the following manner:—

(3.) By adding another salt containing a different acid, an oxy-lead compound may be obtained with two acids, e.g., the above-mentioned oxychlorocarbonate:—

The same body may also be prepared from the basic chloride as follows:—

—F. H. L.

XIV.—TANNING, LEATHER, GLUE, SIZE.

Unhairing, Sweating and Liming Processes for: J. von Schroeder's Researches on. F. H. Haenlein. Dingler's Polyt. J. 1896, 301, 65—70 and 90—95.

For what is known concerning the rationale of "Unhairing," consult Villon (*Traité pratique de la fabrication des cuirs et du travail des peaux*) and Eitner (*Der Gerber*,

1875, 3; 1877, 49; 1880, 111; 1881, 51; 1888, 159, 198; 1891, 13; 1892, 65, 223.) Compare also this Journal, 1890, 461 and 549.

A brown- and black-haired ox-hide was washed, cleansed from adhering flesh, &c., trimmed, and cut up into squares of 10 cm. side. These were immersed in successively stronger salt solutions until they no longer absorbed salt from saturated brine, and were finally preserved in brine to which access of air was prevented. When a square was required for an experiment it was restored to its original condition by 2—3 days' washing in running water. The brown-haired squares were, on the average, somewhat heavier than the black-haired.

As a sweating pit, an ordinary moist chamber, such as is used by the bacteriologist, served, and in this the pieces of hide were laid on dishes, hair side up; the temperature was kept at 16° C. Signs of putrefaction were noted after three days, and after five days one of the pieces could be easily unhaired by a horn spatula. Thus this period may be considered the normal time for unhairing at 16° C., and this is consonant with practice. The epidermis was to a great extent removable as a whole, so that the hair retained its normal condition—a fact emphasising the epidermoid character of the hair.

A second piece of hide was removed from the chamber after six days, and was easily unhaired by the spatula, with the exception of the usual "ground hairs," which, though easily removed by forceps, were too short to be caught by the spatula; there is thus no real difference between "ground hairs" and other hairs, as has been stated. A third piece of hide was unhaired after 8½ days, without any damage to the grain; but a fourth piece, which remained in the chamber for a month, suffered materially. It was found that a piece of hide from which the salt had not been washed could not be properly unhaired until after a sojourn of five months in the chamber, illustrating the retardation of the sweating process effected by salt.

Experiments on the influence of the proportion of lime used and of the addition of stale or partially stale lime-liquor to the limes, on unhairing by this process, were carried out by immersing the hide pieces, freed from salt, in diverse liquors, varying from pure water and water containing the common proportion of lime (6 kilos. of caustic lime per cubic metre of water), to a magma of 300 grms. of quick-lime in a litre of water. In some cases, liquor which had been already used in a tanyard was added, and in every case the proportion of ground hide to unhairing liquor was 1:4·8. In the result it was found that within wide limits the proportion of lime has no influence on the unhairing process, and that immersion in water cannot be substituted for sweating. The influence of the proportion of lime in the plumping of hide, was not considered in these experiments. When the salt was left in the hides it had no appreciable influence on their unhairing by lime.

The detailed experiments lead to the inference that the liming process is not dependent for its depilatory action on the presence of bacteria, and is effective by virtue of alkalinity alone. This result contradicts Villon's conclusion (*loc. cit.*).—A. G. B.

Tannin and Colouring Matter contained in the Bark of Myrica nagi. A. G. Perkin and J. J. Hummel. Proc. Chem. Soc. 1896, [168], 145.

Myrica nagi is an evergreen tree, belonging to the Myricaceæ occurring in the sub-tropical Himalayas, in the Khasia Mountains, the Malay Islands, and Japan. The bark, which is used as a tanning agent, and occasionally for medicinal purposes, was found to contain a yellow colouring matter. This formed yellow needles, closely resembling quercetin, having the formula $C_{15}H_{10}O_8$. In strong solutions of alkali it dissolves with an orange colour, which, on dilution and exposure to air, becomes first green, then deep blue, and finally red-violet. It dyes shades which, in their general character, closely resemble those produced by quercetin and fisetin. With fused alkali it yields *phloroglucol* and *gallic acid*. This is probably a tetrabromo derivative of the colouring matter, but, on account of its somewhat peculiar properties, it will require further

examination. The results of this investigation show that this colouring matter, for which the name *myricetin* is proposed, is most probably a hydroxyquercetin. Its colour reactions with dilute alkali are probably due to the oxidation of the pyrogallol nucleus it contains. The amount of colouring matter, isolated by the method described, varied from 0.23 to 0.27 per cent., and the amount of tannin it contained, according to H. R. Procter, 27.30 per cent.

Quebracho Colorado, The Colouring Matter of. A. G. Perkin and O. Gunnell. *Proc. Chem. Soc.* 1896, [168], 158.

The wood of *Quebracho colorado* constitutes the tanning matter "quebracho," which is suitable for the production of Morocco leather, and, moreover, in conjunction with alum, it gives the leather a bright yellow shade, instead of the darker colours prepared in the ordinary way. Jern (Bull. Soc. Chim. 33, 6) found it to contain a tannin differing from those of oak bark and chestnut wood. According to Arnaudon (Watts' Dict. Chem. 8, 1732), it contains a yellow colouring matter.

The colouring matter, $C_{15}H_{10}O_6$, forms glistening yellow needles, dyeing shades similar to those of quercetin, and yielding compounds with mineral acids. Its dyeing properties were identical with those of fisetin, $C_{15}H_{10}O_6$, the colouring matter of young fustic (*Rhus cotinus*), and there could be little doubt that it was fisetin.

A second substance, $C_{14}H_{10}O_{10}$, forming minute prisms, was also isolated, and was found to be *ellagic acid*, and further, the presence of a considerable quantity of *gallic acid* was detected, these latter being, no doubt, chiefly formed during the isolation of the fisetin from the quebracho.

Degreasing Leather, Impts. in the Method of and Machines for. E. W. Wright and W. Monk, both of Nottingham. Eng. Pat. 10,752, May 19, 1896.

ACCORDING to this new method, the skins to be treated are immersed in a "warm liquid volatile solvent," the nature of which is not further specified, and means are provided for the constant agitation of either the skins, or the solvent, or both, throughout the treatment. After about one hour's treatment with the solvent, the latter is run off, and the skins are dried by allowing hot air to pass over and between them, the vaporised solvent being condensed by suitable means. The extracted grease is recovered by evaporation of the solvent.

The machinery described, principally concerns (1) the treatment of the air, which is used over and over again, whether for agitation of the solvent or for evaporation of the solvent still adherent to the drying skins, and (2) the keeping apart of the skins during treatment.—E. R. B.

Chrome-dressed Leather, Process [Steaming at 100° C.]
for Hardening. K. Möller, Brackwede, Germany. Eng.
Pat. 11,695, May 29, 1896.

THE inventor hardens chrome-dressed leather, so as to render it suitable for boot soles, &c., by subjecting it for varying lengths of time, in the presence of water, to a temperature of about 100° C.—E. R. B.

XV.—MANURES. Etc

Leather Refuse, The [Manurial] Value of. J. B. Lindsey.
J. Amer. Chem. Soc. 1896, 18, 565—575.

THE experiments here described show that dissolved leather, prepared by heating finely ground sole leather with sulphuric acid and neutralising the mixture with chalk, is a source of nitrogen which is as available for plant food as is the average animal matter used for fertilising purposes.

The percentage of nitrogen in the dissolved leather used by the author was 0.97. If the quantity of nitrogen obtained by the experimental crops from sodium nitrate be called 100, then that obtained from dissolved leather was 70. Wagner gives the following relative values of nitrogenous manures:—

Sodium nitrate	100
Ammonium sulphate	90
Dried blood, ground horn, and green plants	70
Ground bone, ground fish, and flesh	60
Stable manure	45
Ground wool	30
Ground leather	20

XVI.—SUGAR, STARCH, GUM, Etc.

Sugar-Cane, Occurrence of Amines in the Juice of.

J. L. Beeson. J. Amer. Chem. Soc. 1896, **18**, 743—744.

THE presence of amines in the products of the sugar beet has long been known, but their occurrence in the juices of the sugar-cane has not been recognised prior to the present sugar season. By the action of heat on the precipitate obtained by the addition of lime-water to cane-juice, the author has obtained a product having the general properties of an amine, but he has not been able to establish its identity.—A. K. M.

Sugar, Inversion of, by Salts. J. H. Long. J. Amer. Chem. Soc. 1896, **18**, 693—717. (See also this Journal, 1896, 550.)

In the experiments described in this paper, the solutions employed, contained 20 per cent. of cane-sugar and varying amounts of each of the salts, the inversion being carried out at a constant temperature of 85° C. The rotation of the solutions was determined at intervals, and the rate of inversion thus ascertained. With some of the salts the velocity coefficient K was practically constant, with others it increases with the time, and with others again it decreases. These results may be roughly tabulated as follows:—

These results may be roughly tabulated as follows :—

Potash alum	K constant.
Ferrous sulphate	K increases slowly.
Ammonium ferrous sulphate	" "
Zinc sulphate	" "
Cadmium chloride	" "
Manganous sulphate	K increases rapidly.
" chloride	" "
Lead nitrate	" "
Ferrous chloride	K decreases rapidly.
" bromide	" "
" iodide	" "

Sugars, Transformation of, by Lead Hydroxide. C. A. Lobry de Bruyn and A. von Eckenstein. Rec. trav. Chim. des Pays-Bas. 1896, **15**, 92.

LEAD hydroxide reacts on sugars in a manner analogous to that of the hydroxides of potassium and sodium, by inducing molecular re-arrangement. Glucose yields mannose, but no fructose. The latter sugar undergoes alteration on treatment with lead hydroxide, but, contrary to the effect produced by the alkalis, neither glucose nor mannose results. It is supposed that in the course of the mutual transformation of glucose, fructose, and mannose by the action of alkalis, another non-acid body of greater reducing power is formed, but its nature is not yet elucidated. Like the alkalis, lead hydroxide acts on the reducing bodies

(lactose and maltose), forming galactose and glucose. From these researches the authors disagree with Svoboda's opinion that lead acetate decomposes sugars, finding that decomposition, with the formation of lactic acid, ensues only after the prolonged reaction of caustic alkali.—C. S.

XVII.—BREWING, WINES, SPIRITS, Etc.

Moulds which appear to Partake of the Nature both of Yeasts and Moulds. A. Jorgensen. Centralblatt für Bakteriöl. 1896, 42.

THE author has observed the occurrence of denarium-like moulds in beer, and that they produce an unpleasant smell and turbidity. He recommends that a careful note be made of their occurrence when examining air, water, or beer.

This mould forms at first the usual white mycelium, but later gives rise to oidium-like bodies, which sooner or later bud. After some time the growth separates into yeast-like cells, and the liquid acquires an unpleasant smell, and is turbid.—A. L. S.

Pure Yeasts and their Nutrition. H. Seyffert. Zeits. ges. Brauw. 1896, 19, 318.

A PURE yeast which had been successfully used for pitching during two years, gradually lost its admirable "breaking" properties, and, although still perfectly pure, assumed a foreign flavour, rendering rejection necessary. After prolonged attempts to find a suitable yeast from a large number of cultures, the author came to the conclusion that the source of failure lay in the nutrient media employed rather than in the yeasts or methods of culture, and a series of ash analyses revealed a paucity of lime both in the wort and in the yeast used in the brewery, due to the low percentage (1.39 CaO per 100,000) of lime in the water used. Yeast from external sources soon became poor in lime when used in this wort, but recovered when lime was added to the goods.

Experiments were made with fermentations in wort with 20 grms. of added gypsum per hectolitre, as well as in worts made from water, with half that amount of added gypsum, and in worts from barleys steeped in waters with and without such addition. In the result the presence of gypsum was found beneficial, not only in the nutrition of the yeast, but also in steeping and malting, by preparing the ground for a normal development of the organism. When a wort poor in lime was still further deprived of that constituent by dialysis, a boiling fermentation resulted. A number of media otherwise unsuitable for yeast culture may be rendered available, at least for the normal development of various races of yeast, by the employment of lime.

—C. S.

Yeast, Fermenting Power and Activity of. E. Duclaux. Ann. de l'Inst. Pasteur. 1896, 119—127 and 177—189.

THE term fermenting power, was introduced by Pasteur to indicate the ratio between the amount of sugar fermented and the amount of yeast employed in the fermentation. This ratio must not be confused with the fermenting activity which is the measure of the rapidity of the fermentation.

The element of time does not enter into the definition of fermenting power; this factor corresponds to the idea of mechanical work, a certain amount of work being necessary to transform a definite weight of sugar; it is not a characteristic of any one yeast, but varies with the conditions of experiment. A condition which profoundly affects its value, is the presence or absence of oxygen; as this varies between maximum limits, the fermenting power varies between such great ratios as 4 and 200.

The idea of fermenting power stated in simple terms, is, that the sugar transformed by a given weight of yeast is greater, as the amount of oxygen is less. In contact with air the greater part of the sugar is used up by being converted into carbon dioxide and water; only a small part is transformed into alcohol. On the other hand, if the supply of oxygen be deficient, an interior combustion of the sugar is set up, and a greater yield of alcohol is obtained. Thus the fermenting power depends both on the *quality* and the *quantity* of the reaction.

The ratio of fermenting activity is one which is more readily understood; it is equal to the fermenting power in a unit of time; thus the amount of sugar that will be transformed in a time T, by an amount of yeast L, is $Q = ALT$, A being the activity. If fermentation be started with a small quantity of yeast, increase of yeast will take place and the quantity L will be an amount intermediate between the amount of yeast sown and the amount existing in the solution at the end of the experiment. The author considers it to be about $\frac{1}{3}$ of this latter amount (Microbiologie, 419).

Besides the quantity of sugar (Q) which has been fermented, a further portion has been employed in the growth of the yeast; this amount is almost equal to the amount of yeast (L) and may be denoted by the expression ML where M nearly equals unity.

The whole weight of sugar used is:— $S = ML + ALT$. The fermenting power is the ratio $S : L = P$; hence $P = M + AT$. This expression resembles that expressing uniform motion in dynamics, P being comparable to space traversed, and A to velocity. Fermenting power is therefore a more complex quantity than fermenting activity, and involves a consideration of time. Duclaux further interprets this equation by considering the two latter terms separately; M is the amount of sugar completely burnt to carbon dioxide and water and AT the amount fermented and producing alcohol, carbon dioxide, succinic acid and glycerin. The first he calls the constructive amount and the second the maintaining one.

Turning to Pasteur's experiments (Études sur la Bière, chap. 6), and considering 24 hours as the unit of time; then under aerobic conditions, $P = M + A = 4$; under suitable conditions M might have a value 2 then we should have a value for $A = 2$. Under anaerobic conditions we have $P = M + 90A$, when taking the same value for M, we get $A = 1.9$. The two values of A are very close.

These two extreme cases show that when the fermentation is very rapid, that is, T is very small, only the first term (M) of the above equation is of importance, whereas when the fermentation is slow, it is only necessary to consider the second term. A fermentation may thus be considered as divided into two parts; in the first the yeast increases at the expense of the sugar, and very little fermentation takes place; in the second, very little yeast growth takes place, but considerable fermentation.

When we try to interpret these equations experimentally, they do not appear to be so simple. If a trace of yeast be sown in a suitable liquid, it commences to multiply very rapidly as long as there is oxygen in solution, and as the oxygen becomes used up, the growth slackens. If now there be an excess of sugar, the fermentation proceeds without any appreciable increase of yeast. If the maximum growth be not reached during fermentation, it is produced when this is finished; this is what Pasteur called *la vie continuée*.

If we now turn our attention to the activity, that is the quantity of sugar fermented by the unit weight of yeast in the unit of time, we find this factor varies with the conditions of experiment. Under aerobic conditions it appears to be very great, and is characterised by a large yeast growth; under anaerobic conditions it is characterised by a free production of alcohol, and the number expressing the activity may be great or small, the variation depending on the quickness or slowness of the fermentation.

Duclaux considers that A. J. Brown (J. Chem. Soc. 1893, 369; and 1894, 911) has confused the notion of fermenting power and activity. He selects two groups of experiments in particular for criticism; the first series is summarised in the following table:—

No.	Duration of Experiment.	Grms. of Sugar fermented.	Weight of Yeast.	Number of Cells.	Fermenting Power.	Activity of the Yeast.
	Days.					
1	5	2.5	0.124	8.51	20.2	..
2	5	5.0	0.155	9.94	32.0	..
3	7	10.0	0.177	10.44	56.0	5
4	12	20.0	0.140	11.17	143.0	12
5	20	25.2	0.138	12.26	182.0	9

These experiments Duclaux does not consider to be comparable, as the amounts of sugar in solution vary so much. The last three experiments are, however, fairly comparable as far as the fermenting activity is concerned, as in the equation for calculating this ($P = M + AP$) the value of M is sufficiently small to be negligible. The activities thus calculated are given above, and agree as closely as can be expected. Duclaux states that there is nothing in these experiments in opposition to Pasteur's theory. He also calculates the activity in another series of experiments which Brown made to show that the same number of yeast cells could ferment 30 or 10 grms. of sugar; the activities are 7.7 and 7.2, that is, they are practically the same, again confirming Pasteur's theory.

Duclaux next proceeds to consider the experiments of Giltay and Aberson (this Journal, 1895, 1764). If the well-known equation, $C_6H_{12}O_6 = 2C_2H_5OH + 2CO_2$, were at all accurate, it would be easy to determine if less alcohol and more carbonic acid were formed under certain conditions, that is to say, if a portion of the alcohol were completely oxidised to carbonic acid; but as the reaction cannot be so simply stated, this problem is surrounded with difficulties which Duclaux does not consider have been overcome. Amongst other objections, he considers that a portion of the alcohol was probably carried over into the potash bulbs together with the carbonic acid. He also objects to the experiments made in a current of air containing 20, 50, and 100 per cent. of oxygen, as they were not made on the same day, and even then he considers the differences in the amounts of alcohol oxidised to be small; and that the "respiration" of the yeast is a fairly constant quantity.

Hansen and Pedersen conclude that, whilst aeration increases the rapidity of multiplication of the yeast, it diminishes its fermenting power. This is in accord with Pasteur. They, however, employed different methods, estimating the consumption of sugar by the decrease of the specific gravity, and counting the yeast cells instead of weighing them.

Sowing 10 cells per unit of volume, they found that for equal quantities of sugar fermented in non-aerated wort, there were 112 cells, and in the aerated one 234 cells per unit of volume; and in another experiment 73 and 145 cells respectively in the non-aerated and aerated solutions. These experiments are not directly comparable, as the time was different in each one; in the first two it was three and two days, and in the second pair, two and one and a half days respectively.

If S denote the weight of sugar fermented, L the quantity of yeast, and A the activity in the non-aerated fermentation, and L' and A' the same in the aerated one, then $S = ML + 3AL$, and $S = ML' + 2A'L'$, and as $L' = 2L$ we get $3A = M + 4A'$.

Similarly, from the second pair of experiments, $2A = M + 3A'$.

The values of A , M and A' in these two equations are not the same, but we see that whatever the value of M is, that A is greater than A' ; that is to say, the activity of the yeast is greater in the absence of air than in its presence, which is Pasteur's statement.—A. L. S.

Malt, The Proteids of. T. B. Osborne and G. F. Campbell. J. Amer. Chem. Soc. 1896, 18, 542–558.

The malt employed in this investigation contained—

1. *Bynedistin*, a globulin far more soluble in very dilute salt solution than edistin, the globulin of barley, and differing moreover from the latter in containing more carbon and less nitrogen. Bynedistin dissolved in 10 per cent. salt solution gives a turbidity at 65° C., and a flocculent coagulum at 84° C., but even after protracted heating at 100° C. the coagulation is incomplete. The proteid is partly precipitated by saturating its solution with magnesium sulphate.

2. *Leucosin*, an albumin, identical in composition and properties with that obtained from wheat, rye, and barley. 3. A *Protoproteose*, readily precipitated from aqueous solution, by adding an equal weight of alcohol. Of the same composition as leucosin. 4. A *Protoproteose*, less readily precipitated by alcohol, and differing in composition from the preceding. 5. A *Deuteroproteose*. 6. A *Heteroproteose* in extremely small amount. 7. *Bynin*, a proteid insoluble in water and saline solutions, but readily soluble in dilute alcohol. 8. A proteid insoluble in water, saline solutions, and dilute alcohol. The following proportions of these constituents were found:—

	Per Cent.
Proteid, insoluble in salt solutions and in alcohol	3.80
Glycin, soluble in dilute alcohol	1.25
Bynedistin, leucosin, and proteoses (coagulable soluble in water and salt solutions) (uncoagulable)	1.50
Total proteids	7.84

It appears, therefore, "that during germination, the proteids of barley undergo extensive changes without acquiring, or before acquiring the properties of proteoses; that hordein disappears, and a proteid soluble in alcohol, of entirely different composition, takes its place; and that edistin also disappears and is replaced by a new globulin. The albumin, however, appears to be unchanged in its characters, but its quantity is increased."—H. T. P.

Malting Process, The Effect of Water containing Gypsum on the. G. Felix. Allg. Brauer und Hopfen Zeit. 1896, No. 77.

The author has examined malts prepared respectively with a hard water containing about 323 parts of solid matter per 100,000, of which 212 were gypsum, and a water containing 72 parts of solid matter per 100,000, of which 46 were gypsum; and he finds that the malts prepared from the latter were much more satisfactory in every way; he is inclined to consider that the reason is that the hard water does not remove a proper quantity of soluble matter from the grain.—A. L. S.

Potatoes, The Preservation of. Paulsen. D. Landwirtschaft. Zeit. 1896, No. 4.

The author recommends that the stock of potatoes in distilleries be kept in heaps covered with straw and earth, and protected from the weather by shedding. He states that up to the first occurrence of frost, unripe diseased sorts may be used with advantage.

When potatoes are stored for any length of time changes take place in their composition, the nature of which are chiefly dependent on the temperature, and may be classed under three heads.

(1.) A sugar formation from starch by the action of a ferment.

(2.) A loss of sugar by oxidation.

(3.) A starch reproduction from sugar.

The second decomposition increases considerably with the temperature, the first and third nearly neutralise one another at temperatures between 6°–20° C. and the formation

of sugar being always in excess of the reproduction of starch; below 6 C. the former decomposition is much in excess of the latter, and this explains how it is that frost renders potatoes sweet.—A. L. S.

Potatoes, The Fermentability of the Wort Prepared from Different Varieties of. J. Scheibner. Zeits. für Spiritusind., 1896, 223—224.

The author has determined the yield of alcohol which can be obtained from different varieties of potatoes, and finds that some small tubered sorts yield less alcohol than other large tubered ones; the yield of alcohol being calculated on the amount of the saccharometric extract obtained from the various sorts. This result is caused by the fact that the former yield worts which do not ferment so completely as those yielded by the latter.

The author has tried to complete the fermentation of these extracts by the addition of yeast and malt, and also by prolonging the time of fermentation, and by a combination of these methods he succeeded in raising the yield of alcohol. He suggests that by the use of Pombe or Logos yeasts a better yield may also be obtained.—A. L. S.

XVIII.—FOODS; SANITATION, WATER PURIFICATION, & DISINFECTANTS.

(A).—FOODS.

Bread from Flour of Different Qualities, Nutritive Value of. A. Girard. Comptes rend. 1896, 122, 1382—1388.

The author has already shown (*ibid.*, 1309), that the alleged superiority of brown over white bread, as regards nutritive value, is unfounded, since the amount of gluten is practically the same in both.

With regard to phosphoric acid, the average amount found in the husks was 2.37, in the kernel, 0.30 per cent. But when the relative amounts of husks and kernel in flours are taken into account, the differences in white and brown bread are small; and when the total amounts of phosphoric

acid in ordinary rations are calculated, the differences introduced by the bread being white or brown, are quite insignificant. In any case there is a large excess of phosphoric acid in the food over the highest estimate of what is normally eliminated, (*viz.*, 3.19 grms. per day).

It is concluded that for general consumption white bread, well leavened, and prepared from 60 to 65, or, at the most, 70 per cent. flour, is the best. Brown bread may be reserved for those who prefer the flavour, and for those whose digestive powers are uncertain.—N. H. J. M.

Milk, Preservation of, by Potassium Chromate. J. Froidevaux. J. Pharm. Chim. 1896, 16, 155.

The addition of potassium bichromate to a sample of milk, 4 grms. to the litre, will prevent its coagulation for four months. Lately the neutral chromate has been used to preserve milk intended for consumption. The author finds that the quantity employed, 0.04 grm. per litre, is practically useless, and that at least 0.2 grm. is necessary; this quantity, however, gives an appreciable coloration. To test for chromates in milk, the ash of 10 c.c. should be extracted by a little water, the solution slightly acidified by nitric acid, carbonate of magnesia added to neutral reaction, and then silver nitrate. This reagent must be present in some quantity to throw down the chlorides and phosphates. A red coloration indicates the presence of the chromate. When, however, the chromate is present in less proportion than 0.05 grm. per litre, the phosphates in part mask the coloration; a more delicate test is to add to the ash, water slightly acidified by sulphuric acid and then guaiacum tincture, the presence of a chromate is shown by an intense blue coloration which disappears rather quickly.

—A. C. W.

PATENTS.

Meat, Frozen, and other Articles of Food [Thawing in Hot Oil], Impts. in Treating. J. A. Linley, London. Eng. Pat. 13,707, July 17, 1895.

The meat, &c., is thawed by immersing it in hot beef fat, mutton fat, or a highly refined oil. The fatty coating is afterwards removed by beating, or other convenient process. The inventor claims that no moisture of the air condenses on the meat during the thawing and the article does not become sodden or deteriorated.—L. de K.

Impts. in and Means for Preserving [Economy of Vessels]. P. Griffin, Bath. Eng. Pat. 15,255, Aug. 14, 1895.

A glass or earthenware vessel with a suitable opening through which the food is introduced or withdrawn, is constructed. The opening is hermetically closed by a movable air-tight stopper held in position by a screw or bayonet joint. The stopper is provided with a small hole, to allow the escape of steam or vapour, which is afterwards hermetically closed by means of a suitably arranged plug or stopper.

The vessel is filled with the food to be preserved, and if necessary, a certain amount of preserving fluid, such as syrup, is added, and the vessel is then placed for some time in a boiling water-bath. Another plan is to pass steam by means of another hole in the interior of the vessel.

The chief claim of the inventor is that the vessel can be used over and over again, whilst ordinary sealed metallic cans are no longer any use. There is also no danger of metallic contamination in the new process.—L. de K.

Chemical [Acid Treatment Decortication], Improved Process of and Apparatus for Use therein, applicable for the Treatment of Grain. H. H. Lake, London. From E. de Moerloose, Brussels. Eng. Pat. 15,765, Aug. 21, 1895.

The grain is soaked in water containing 0.5—3 per cent. of hydrochloric acid at from 30°—50° C., and a small quantity of a suitable oxidising agent, such as permanganate or bichromate of potash, not exceeding 2 or 4 grms. per 100 litres. To ascertain whether the soaking has been sufficient, the grain is from time to time pressed between the fingers, which should cause the bark to readily break up and separate. The grain is now passed, in a current of

water, between moving brushes with plane or cylindrical surfaces; or they may have their bristles arranged in alternately projecting and receding rows.—L. de K.

Milk, Humanised Condensed. C. G. Moor, London. Eng. Pat. 20,219, Oct. 26, 1895.

High-class cows' milk is concentrated to one third. 33 lb. of this are then mixed with 12 lb. of cream, 10 lb. of milk-sugar, $\frac{1}{2}$ lb. of phosphate of soda, and 44 lb. of distilled water. Before use, the mixture is diluted with twice its bulk of water.

The inventor claims that it is practically identical with human milk, being rich in sugar but poor in albuminoids. —L. de K.

Tea or other Matters, Impts. in and Apparatus for the Production of Extracts of [by Percolation]. G. H. Roque-Dabbs, Shanklin, Isle of Wight. Eng. Pat. 3192, Feb. 12, 1896.

FINELY-DIVIDED tea (tea dust, for instance) is introduced into a series of percolators and water is allowed to pass through, the percolators being heated by boiling water or steam. To obtain the whole of the soluble matter, the tea is again exhausted and the liquid is concentrated by evaporating in a vacuum pan before mixing with the first percolate. —L. de K.

Organic Alimentary Substances, Solid: Improved Process for Preserving. F. O. Jacob, Paris, France. Eng. Pat. 12,150, June 3, 1896.

THE use of high pressure carbon dioxide and methanal vapours, is claimed.—L. de K.

Milk, Impt. in or relating to the Treatment of, for the Purpose of suiting it to Individual Digestions. G. H. Walker, G. E. Gordon, and J. H. Waterhouse, of Boston, U.S.A. Eng. Pat. 14,196, June 26, 1896.

SEPARATION of cream and non-creamy portion, and the use of milk sugar.—L. de K.

Preserving Organic Substances, Improved Process of, more particularly applicable for Alimentary Substances. C. L. Bachelier, Paris, France. Eng. Pat. 14,581, July 1, 1896.

THE use of high pressure carbonic acid, vacuum, and cold is claimed.—L. de K.

(B).—SANITATION: WATER PURIFICATION.

Aniline Poisoning. Leipziger Färber u. Zeugdrucker Zeit. 45, 346.

ANILINE poisoning may occur by the inhalation of its vapours, by direct introduction into the circulatory system, and through absorption by the skin. The characteristic symptoms are:—General depression, lassitude, weakness, difficulty of speech, and blue lips; the patient looking as if intoxicated. Vomiting gives relief, and in fresh air the patient soon recovers. Astringents are said to act beneficially, but alcohol aggravates the effects of the poisoning. It has been observed that most cases of poisoning have been caused by aniline being splashed on the clothing of work-people. In such cases the clothing should at once be changed, and the parts of the body touched by aniline should be washed with water acidulated with hydrochloric acid. The rooms where aniline is used should be well ventilated. Nitrobenzene and toluidine are said to produce effects similar to those of aniline.—I. S.

Nitrates, Reduction of, by Bacteria, and Consequent Loss of Nitrogen. E. H. Richards and G. W. Rolfe. Techn. Quarterly 1896, 9, 40—59.

IN order to reproduce the conditions of a water containing decaying organic matter and nitrates, solutions were prepared from tap-water, milk, and potassium nitrate. These were allowed to decompose, and analyses made at various stages of the decomposition. The conclusion drawn by the authors from their results is that when a decaying organic solution

which contains nitrates does not furnish sufficient oxygen for the bacteria, the latter derive their supply from the nitrates, which they reduce first to nitrites and finally to free nitrogen. In manuring, since nitrates may be readily destroyed through adding too much sewage, the amount of the latter should always be regulated so as to obtain as much oxygen as possible. Artificial aëration, by blowing air through the bulk, is useless; whilst the disposal of the sewage in very thin layers appears to be the most advantageous course. It is suggested that growing plants should be supplied with only as much nitrogen as they can assimilate. Even under the most favourable conditions of aëration some loss of nitrogen appears almost inevitable when decomposing organic matter is added to a nitrified water or soil, since certain bacteria prefer to obtain their oxygen supply from nitrogenous combinations. These results are considered to throw light on the greater efficiency of coarse than of fine material in sewage purification, the aëration being more effective, and less nitrogenous matter being retained to promote the growth of reducing bacteria.—C. A. M.

PATENT.

Sewage and Impure Water, Impts. in the Treatment and Purification of [Using Benzoic Acid and Sol. Benzoates with Carbon and Clay]. J. W. Slater, Tollington Park, Middlesex, and the Native Guano Co., London. Eng. Pat. 18,093, Sept. 27, 1895.

THE sewage is treated with a mixture of equal weights of clay and carbon, then with benzoic acid or soluble benzoates, and after being well mixed, cake alum or aluminium chloride is added, the quantities of these various ingredients depending on the quality of the sewage. Benzoic acid or soluble benzoates are added to the effluent resulting from the treatment of sewage by precipitation or filtration, and secondary fermentation is thus prevented.—J. L. B.

(C).—DISINFECTANTS.

PATENTS.

Sheep Dipping Powders [Sulphur and Arsenical Powders], Impts. in the Manufacture of. F. W. Passmore and Jeyes' Sanitary Compounds Co., Lim., London. Eng. Pat. 11,921, June 19, 1895.

A SOLUBLE sulphur powder is prepared by mixing stated proportions of sodium thio-sulphate and oxalic acid, both anhydrous. The oxalic acid may be replaced by sodium or potassium acid sulphate, cream of tartar, or other dry acid substance. The powder must be preserved from becoming damp, and for use is dissolved in water, forming, owing to the sulphur precipitated, a milky emulsion, so that the sulphur reaches every part of the fleece to which it is applied. To prepare an arsenical powder, arsenic acid, or a soluble arsenic salt, sodium arsenate, preferably, is mixed with the described powder, which, when dissolved for use, yields a solution containing arsenic sulphide as a finely-divided precipitate.—E. S.

Drains and Sewers, Improved Means of [Carbon or Wood Dust, Manganate of Soda, and Sulphuric Acid], Purifying the Air of, or of Suppressing Noxious Vapours generally. R. H. Reeves, Putney, Surrey. Eng. Pat. 18,185, Sept. 28, 1895.

THIS process consists of dropping, in the space requiring purification, sulphuric acid on dry manganate of soda mixed with carbon, fine wood, or other dust. When the evolution of gas has ceased, water is added to the residue, a solution of permanganic acid is thus formed, which treats the sewage or other matter flowing through the drains.—J. L. B.

Disinfectant, Improved, and Cleansing and Purifying Compound. E. Burton, Camberwell. Eng. Pat. 18,229, Sept. 30, 1895.

A SOLUTION of the required strength, of carbolic acid, permanganate of potash, oil of eucalyptus, &c., &c. is added to disintegrated moss, and the preparation is then subjected to heavy pressure.—J. L. B.

Aldehydes, Impts. in or relating to a Process and Apparatus for the Preparation of. A. J. Boulton, London. From G. Barthel, Dresden, Germany. Eng. Pat. 3998, Feb. 21, 1896.

THE process claimed consists in diverting a portion of a stream of alcohol vapour and burning this round the main stream, so as to prevent the admission of an excess of oxygen. The apparatus claimed has a combustion chamber closed at one end, and a separate vaporising chamber, the outlet pipe from which is provided with a large opening directed towards the open end of the combustion chamber, and with a smaller opening directed against the closed end. On igniting the vapours, the stream from the latter opening surrounds that from the former, and prevents access of oxygen to it. Air for the flame enters the burning-tube by holes in its walls.—A. C. W.

Gaseous Mixtures, mainly Formaldehyde, for Disinfecting Purposes, Process and Apparatus for producing. Société Anonyme de l'Institut Raoul Pictet, Fribourg, Switzerland. Eng. Pat. 11,557, May 27, 1896.

THE process for the production of mixtures of formaldehyde, which consists in passing a current of hot gases over trioxymethylene, is claimed, together with an apparatus for producing such mixtures. This essentially consists of two concentric cylinders, between which pass the gases from a fire or burner, the lower part of the inner cylinder is surrounded by a worm, through which the gas employed passes to the bottom of this cylinder, where it goes through a layer of trioxymethylene. The upper part of the inner cylinder, which is narrower and serves for the introduction of the aldehyde polymer, is surrounded by another worm, through which the gases pass from the cylinder and where the vaporisation of the polymeride is completed. The apparatus may also be modified to admit water or formaldehyde solutions and so deliver moist gases.—A. C. W.

XIX.—PAPER, PASTEBOARD, Etc.

PATENTS.

Knots and other Matters, Separating, from Wood Fibre in the Manufacture of Wood Pulp; Impts. in the Method or Means for. The Kellner-Partington Paper-Pulp Co., Ltd., Manchester. From N. Pedersen, Sarpsborg, Norway. Eng. Pat. 15,783, Aug. 22, 1895.

THE object of the invention is the removal of the knots, dirty pieces of bark, &c., from wood fibre in the manufacture of wood pulp. It consists in passing the disintegrated wood, before digestion, through a tank of water or saline solution (according to the specific gravity of the wood employed) on a travelling apron or similar device, the material being thoroughly soaked in transit by rotating paddles, to ensure removal of air-bubbles and free the lighter particles of pure fibre from the heavier impurities, which fall to the bottom and are mechanically removed.

—O. H.

[Paper Filling] Waste Materials obtained in the Manufacture of Ammonium Compounds; Improved Process or Treatment of, to Produce a Substance suitable for Use as a Paper Filling in the Manufacture of Paper. W. Brothers, Rawtenstall, Lancaster. Eng. Pat. 18,503, Oct. 3, 1895.

THE waste materials described in the title, or materials of other origin, consisting essentially of a mixture of calcium carbonate, sulphate, and hydroxide, are suspended in water, and furnace gases are blown through, until the free lime present is carbonated. The neutral compound obtained of calcium carbonate and sulphate may then be applied for paper-filling or otherwise.—E. S.

The Residual Liquors produced in the Manufacture of Vegetable Parchment Paper, Impts. connected with the Application and Utilisation of. [Sulphate of Magnesia and Gypsum.] J. S. Rigby, Liverpool. Eng. Pat. 19,008, Oct. 10, 1895.

THE acid-liquors left on parchmentsing paper with sulphuric acid are returned to the bath: the paper is then

further washed in another series of tanks. The tanks used for the first wash are connected to a main pipe leading to a cistern, whence the acid is delivered to the upper part of towers charged with magnesite, and the solution of magnesium sulphate obtained passes into settlers, and then into crystallising tanks. The carbonic acid given off in the process is collected. The weaker sulphuric acid derived from the second series of washing-tanks is led into mechanical mixing apparatus, into which calcium chloride solution is run, gypsum being obtained. Special apparatus is described.—E. S.

Paper, Manufacture of; adapted for being Written or Drawn upon by means of a Metal Style, and for Polishing and Cleaning Metals; Impts. in the. [Mixture of Pulp and an Oxide or Carbonate.] L. Capazza, Brussels, Belgium. Eng. Pat. 9914, May 9, 1896.

THE pulp from which the paper is made is mixed with a stated proportion of an oxide or carbonate, preferably zinc oxide or carbonate; or ordinary paper is coated with the oxide or carbonate in a sizing-bath. Paper thus prepared may be written upon by a durable metallic style, without the use of pencils or of ink.—E. S.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

Pharmaceutical Products, Action of Light upon. A. B. Stevas. Pharm. Journ., Aug. 22, 1896, 165.

THE following descriptive list is given of substances which, according to the United States Pharmacopœia, should be protected from the action of light, either by being kept in dark amber-coloured bottles or in the dark.

Articles affected by Light.—Benzoic acid should be kept in dark amber-coloured, well-stoppered bottles, in a cool place.

Carbolic acid should be kept in dark amber-coloured, well-stoppered vials.

Hydrobromic acid should be kept in glass-stoppered bottles, protected from the light.

Hydrochloric acid, nitric acid, nitric acid dilute, and nitrohydrochloric acid dilute should be kept in dark amber-coloured, glass-stoppered bottles.

Nitrohydrochloric acid should be kept in dark amber-coloured, glass-stoppered bottles, which should not be more than half filled, and kept in a cool place.

Hydrocyanic acid dilute should be kept in small amber-coloured, cork-stoppered vials, in a cool place.

Sulphurous acid should be kept in dark amber-coloured, glass-stoppered bottles, in a cool place protected from light.

Formic acid is darkened by the action of light and air.

Acetic ether should be kept in a cool, dark place.

Ammonium iodide should be kept in small, well-stoppered vials, protected from light.

Amyl nitrite should be kept in small, dark amber-coloured, glass-stoppered vials, in a cool and dark place.

Sulphurated antimony keep in well-stoppered bottles, protected from light.

Apomorphine hydrochlorate keep in dark amber-coloured vials.

Stronger orange-flower water should be kept in loosely-stoppered bottles, in dark place.

Chlorine water should be made fresh, but when kept should be protected from light and air.

Stronger rose water should be kept in a dark place.

Silver cyanide, iodide, nitrate, diluted nitrate, moulded nitrate and oxide should be kept in dark amber-coloured vials protected from the light.

Arsenic iodide should be kept in glass-stoppered vials protected from light.

Bismuth and ammonium citrate keep in well-stoppered bottles protected from light.

Chloral and chloroform should be kept in glass-stoppered bottles, in a cool, dark place.

Ferrie citrate, iron and ammonia citrate, iron and ammonia tartrate, iron and potassium tartrate, iron and

quinine citrate, soluble iron and quinine citrate, iron and strychnine citrate, should be kept in well-stoppered bottles, protected from the light.

Saccharated ferrous iodide should be kept in a cool and dark place.

Soluble ferric phosphate and pyrophosphate should be kept in dark amber, stoppered bottles.

Iron valerianate in a cool, dark place.

Mild mercurous chloride and mercuric cyanide should be kept in dark amber-coloured bottles.

Yellow mercurous iodide should be kept in dark amber-coloured bottles with the least possible exposure to light.

Red mercuric iodide, yellow mercuric oxide, red mercuric oxide, yellow mercuric sulphate, ammoniated mercury and mercury with chalk are to be protected from light.

Iodoform, solution ferric acetate, solution of chlorinated soda and methyl salicylate are to be kept in a cool place, protected from light.

Naphthol keep in dark amber-coloured bottles.

Volatile oils, 23 are directed to be kept in cool places, protected from light.

Physostigmine salicylate and sulphate should be kept in small, dark amber-coloured vials.

Lead iodide is to be protected from light.

Pyrogallol keep in dark amber-coloured vials.

All of the quinine salts should be kept in a dark place.

Resorcin and santonin should be kept in dark amber-coloured vials.

Sodium salicylate, protect from heat and light.

Spirit of nitrous ether in small, dark amber-coloured vials, in a cool place.

Spirit of phosphorus keep in small, dark amber-coloured vials, in a cool, dark place.

Stronium iodide keep in dark amber-coloured glass-stoppered vials.

Terebene should be kept in a cool place, protected from light.

Tincture of chloride of iron should be protected from light.

Other Chemicals acted upon by Light.—The action of light upon silver compounds is a problem upon which a vast amount of study and investigation has been expended. Few investigators agree as to the actual compounds formed, but nearly all have proven that the action is one of reduction.

Silver chloride, when fused repeatedly or until all traces of the nitrate or organic impurities are lost, is unaffected by light. N. de St. Victor discovered that paper coated with egg albumin and dipped in a solution of silver is far more sensitive than when used with the silver salt alone. At the present time silver salts are invariably associated with albumin, gelatin, or collodion in all photographic plates.

Chloral becomes acid on exposure to light and air.

Chloroform, when absolute and all air is excluded, is not acted upon by sunlight, but in the presence of air is rapidly decomposed. The presence of more than $1\frac{1}{2}$ per cent. of alcohol prevents decomposition; smaller quantities retard the action in proportion to the quantity present. In the absence of alcohol chlorine is liberated. In the presence of alcohol the chlorine is converted into hydrochloric acid.

Creosote, when pure, is not acted upon by light, but when a small quantity of tar oils is present, light darkens it.

Sulphurous acid is decomposed by light, forming free sulphur and oxygen. The oxygen combines with a portion of the sulphurous acid to form sulphuric acid.

Hydrocyanic acid is decomposed by light and air, forming different substances under different conditions. The greatest care must be exercised to promote its preservation. The following is the method employed in the prescription department of one American school of pharmacy. A block of wood whose dimensions are 2 by $2\frac{1}{2}$ by 6 ins. is procured. Eight holes of sufficient size that each will accommodate a dram vial are bored in this block. The vials, filled with freshly-made hydrocyanic acid, are corked, placed in the holes prepared to receive them, and the holes closed with corks. When a prescription requiring this acid is received, the acid is taken from one of the vials, and should any acid remain in the opened vial it is thrown away.

Ferric salts.—Inorganic ferric salts, when pure, are stable, but when associated with organic compounds they are invariably reduced to ferrous compounds by the action of light. For example, ferric chloride and the solution of ferric chloride are unaffected by light, while the alcoholic tincture of the solution is partly reduced to ferrous chloride. Hence the U.S.P. directs that it shall be protected. Many of the ferric salts with organic acids are so sensitive to the action of light that they are used for photographic printing. The cyanotypes or blue prints are made by exposing paper coated with a solution of ammonio-ferric tartrate and placed under a negative to the action of sunlight. When the iron is reduced to a ferrous condition, the paper is floated upon a solution of potassium ferri-cyanide, forming ferrous ferri-cyanide. The kallitype printing process is based upon the reduction of ferric oxalate to ferrous oxalate by light. Sodium ferric oxalate acts in a similar manner, producing an orange-coloured image which is developed with a solution containing silver nitrate.

Mercurous chloride, when in the dark, is not acted upon by the air. Exposed to light it gradually darkens, indicating partial reduction.

Mercuric cyanide is affected in a similar manner.

Mercurous iodide is easily decomposed by light into mercuric iodide and mercury. Mercuric oxides, both red and yellow, are partially reduced by light.

Iodoform is decomposed by sunlight with the liberation of iodine.

Volatile oils are easily decomposed and even alcoholic solutions easily affected by the same agent. Therefore not only volatile oils but perfumes also should be protected.

The ornamental display of perfumes in clear glass bottles upon the case or shelves is a mistake. They should be excluded from light.

Spiritus ætheris nitrosi rapidly decomposes under the action of light and air, becoming acid. Samples have been found that had decomposed and refused to give a test for ethyl nitrite.

Syrup of ferrous iodide which has oxidised by the action of air may be completely reduced to the ferrous condition by exposure to sunlight.—A. C. W.

Menthene and Tertiary Menthol, Preparation of. L. Masson and A. Reyher. Bull. Soc. Chim. 1896, 15—16, [15], 965—969.

THE first stage was the preparation of menthyl chloride from secondary menthol by the action of phosphorus pentachloride, added by degrees and in excess, in presence of rectified petroleum spirit. On washing the petroleum solution with water and sodium carbonate, and leaving to evaporate spontaneously, 120 grms. of crude menthyl chloride (from 100 grms. of menthol) were obtained and converted into menthene by heating for some 12 minutes at 150° along with a solution of 75 grms. of potassium hydroxide in 315 grms. of phenol, followed by distillation until the temperature rose to 200° C. The crude menthene, washed with potash and rectified over metallic sodium, yielded 60 grms. of purified substance, boiling at 160° to 166° (uncorrected), and having a sp. gr. of 0.811 at 20° C. It is remarkable for its high *levo*-rotation, $[\alpha]_D = -48^{\circ} 5$. On treating this body with 150 grms. of trichloroacetic acid for half an hour at between 70° and 90° C., and leaving the two in contact overnight, it was found that 47.3 grms. of the acid had entered into combination, i.e., some $\frac{1}{3}$ of a molecule per molecule of menthene. The product, freed from acid, was saponified by alcoholic potassium hydroxide, and the resulting menthol extracted, along with the residual menthene, from water, by means of petroleum spirit, the extract being then subjected to fractional distillation up to 110° C. under progressive reductions of pressure (from 100 mm. down to 23 mm.). The highest distillate (102° — 110°) contained the greater part of the menthol (41 grms.), and yielded, on redistillation, 34 grms. of a colourless, rather oily liquid of sp. gr. 0.8999 at 22° C., consisting of 76.77 per cent. of C and 12.91 per cent. of H. The index of refraction, $n = 1.45979$, equivalent to a molecular refractive power of 47.45, indicates the absence of a double bond: the rotatory power is *nil*. In order to prove the tertiary nature of the product, it was mixed with ordinary menthol and etherified

by the Menschutkin process with pure acetic acid, with the result that only 2 per cent. of the tertiary isomer was affected as compared with 12.5 per cent. of the ordinary menthol.

Of the other fractions, that coming over between 80° and 95° C. chiefly contained dextro-menthene ($[\alpha]_D = 44.2$). This may be accounted for either by the assumption that dextro-menthene was originally present, or that part of the trichloroacetic acid reelected from combination, and in so doing displaced the double bond.—C. S.

Kola, Pharmacology of. P. Carles. J. Pharm. Chim. 1896, 16, 104.

A LARGE proportion of the caffeine in kola is contained in the form of kolanine, a compound of the alkaloid with tannic acid, insoluble in chloroform, but easily soluble in alcohol, and decomposed by alkalis into its constituents in the presence of water or alcohol. According to the author, kolanine does not exist in the fresh nuts, but is formed by the action of the oxygen of the air, due to a laccase. The following method is given for the determination of the caffeine (compare this Journal, 1896, 561, 622):—10 grms. of powdered kola are mixed with 1 gm. of slaked lime and 20 grms. of 80 per cent. alcohol, and dried until the weight is reduced to 13.5–14 grms. The pulverised mixture is four times extracted by boiling on a water-bath with 35 c.c. of a mixture of 100 grms. of chloroform and 20 grms. of 93 per cent. alcohol, the extraction being performed in a flask with air condenser. After evaporation of the solvent and extraction of the residue with water, the solution is evaporated and the alkaloids dried at 100°.—A. C. W.

The "Formopyrine" of Marcourt. F. Stolz. Ber. 1896, 29, 1826.

THIS substance is obtained by the combination of antipyrine with formaldehyde (this Journal, 1896, 372–373).—A. C. W.

Anemonine. H. Meyer. Monatsb. f. Chem. 1896, 17, 283–299.

ANEMONINE is obtained from the crystallisable portion of the extracts from almost all the plants belonging to the anemone and ranunculus group. According to Beckurts (Arch. für Pharm. 230, 182), it possesses the empirical formula $C_{10}H_{12}O_4$, whilst its constitution has also been studied by Hanriot (Bull. Soc. Chim. 47, 683). In two experiments the author obtained 4.8 and 5.2 grms. of pure anemonine from 10 kilos. of fresh *Anemone pratensis*. Besides investigating its properties, he has also prepared several derivatives. Anemonine is easily soluble in boiling alcohol and chloroform, less soluble in benzene and hot water, and scarcely at all soluble in ether and petroleum spirit. From its solution in alcohol and benzene, it crystallises in the form of long, bright needles, and from chloroform in plates, which melt at 150° to a clear, bright yellow liquid. Heated a few degrees above the melting point, anemonine is converted into an amorphous substance which decomposes at 290°. This peculiarity probably accounts for the fact that certain investigators were unable to assign any definite melting point to it. Anemonine is dissolved by alkalis imparting a reddish-yellow or blood-red colour to the solution, which disappears again on acidification. The change is so abrupt that anemonine can be used as an indicator for its own volumetric estimation. In conclusion the author points out that anemonine, $C_{10}H_{12}O_4$, presents a certain amount of similarity, both in constitution and physiological action, to cantharidine, $C_{10}H_{12}O_7$.—J. S.

Pellotine as an Opiate. F. Jolly. D. med. Wochenschr. 1896, 22, 24.

PELLOTINE is a natural alkaloid obtained from *Anhalonium Williamsii*, and forms the active ingredient in the "pellotes" sold in Mexico as narcotics. It is crystallisable, and of a bitter taste; only slightly soluble in water, but readily so in hydrochloric acid, and is represented by the formula $C_{13}H_{19}NO_4 \cdot HCl$. Experiments on 40 patients gave satisfactory results, the smallest quantities being sufficient; subcutaneous injections also proved efficacious.—C. S.

Fennel, Japanese; and its Oil. J. C. Umney. Pharm. J. 1896, 91.

THE Japanese fennel fruit resembles anise in shape, but is more oblong, and has no hair on its surface like the latter. The odour of Japanese fennel is very similar to that of the European variety, and its taste, at first sweet, is marked by the after-bitterness characteristic of the other varieties. The fruits yielded by steam distillation (with the water of the condenser at a temperature of at least 25° C., to avoid separation of anethol), 2.7 per cent. of a pale yellowish oil having an odour similar to that of ordinary oil of sweet fennel. The oil solidifies at -7° C. when stirred, and becomes liquid again at -10° C.; the rather high solidifying point indicates a high percentage of anethol. By fractional distillation of 100 c.c. from a glycerin bath, the following portions were obtained, the quantities being similar to those obtained from French and East Indian fennel oils:—

	Per Cent.
Below 220° C.	26
220°–225° C.	32
225°–230° C.	34
Residue	8

The author found that the terpene constituents of the oil, about 5 per cent., consisted of pinene and dipentene, no phellandrene being present. The oil also contained 10.2 per cent. of fenchone and over 75 per cent. of anethol.—A. S.

Palmarosa Oil. E. Gildemeister and K. Stephan. Arch. Pharm. 1896, 234, 321.

THIS oil, also known as Indian grass oil, false or Indian, or Turkish geranium oil, is obtained from the leaves of *Andropogon Schoenanthus* from Bombay. It consists chiefly of geraniol, and also contains about 1 per cent. of dipentene, traces of methyl heptenon, and between 12 and 20 per cent. of esters, these being geraniol esters of acetic and normal caproic acids.—A. C. W.

Vanilla in Mexico, Cultivation of. J. Soc. Arts, 1896, 44, 716.

THE information given in the paper is taken from the report of Sir H. Dering on the productions of Mexico.

Six varieties of vanilla occur in Mexico, namely, the "mansa," the "cimarrona," the "mestiza," the "pompona," the "puerco," and the "mono," but only the mansa and the pompona are cultivated. The bean, if allowed time to ripen properly, is black and juicy, and will, if well prepared, keep for many years. The beans are gathered, and immersed for half a minute in nearly boiling water, and, after draining, are exposed to the sun. They are then shut up in tight boxes to ferment. When the beans are soft and pliable, they are squeezed so as to evenly distribute the seeds and oily substances contained in them, and are finally divided into five grades according to length, thickness, colour, and appearance. (See also this Journal, 1896, 613.)—A. S.

Calcium Tartrate, Solubility of. H. Enell. Nordisk. Pharm. Tidsskrift. 1896, 3, 196.

ONE part of calcium tartrate is soluble in 2,565–2,632 parts of water, 3,850 parts of concentrated acetic acid, 296–303 parts of 25 per cent. acetic acid, and in 2,280–2,540 parts of saturated acid potassium tartrate solution.

—A. C. W.

Antipyrine, Combinations of, with the Oxybenzoic Acids and their Derivatives. G. Patcin and E. Dufau. Comptes rend. 122, 1335–1338.

1. *Salicylate of antipyrine* [salipyrine] is already known.

11. *Antipyrine para-oxybenzoate* is obtained by mixing a concentrated alcoholic solution of 5.5 grms. of para-oxybenzoic acid with an aqueous solution of 8 grms. of antipyrine. An oily liquid separates and crystallises after some time. The substance may be re-crystallised from boiling water or alcohol. It melts at 78°–82°, is soluble in 130 parts of cold water, much more soluble in boiling water, very soluble in alcohol, and slightly soluble in ether. Ferric chloride gives the antipyrine reaction.

III. *Antipyrine meta-oxybenzoate* is obtained in a similar way, but remains liquid under ordinary conditions. Both of these substances are formed by the union of a molecule of each of the constituents without the elimination of water.

Antipyrine likewise combines with saligenin, forming a liquid substance, but not with methyl salicylate nor anisic acid.—J. S.

Citric Acid Fermentation, Two New Moulds which produce. C. Wehmer. Zeits. für Spiritusind. 1896, 208—209.

Citric acid was detected amongst other acids in a solution on which moulds were growing: Two organisms were isolated which produced citric acid from sugar; and as the author was unable to identify them with any known moulds, he named them *Citromyces Pfefferianus* and *C. Glaber*. In appearance these moulds resemble the common blue moulds, but with practice can be distinguished from them. The most favourable temperature for the germination of the spores is from 18°—25° C. Below 0° and above 25° they do not grow. Before budding, they swell to double their size. Under some conditions there is a production of yeast-like cells, which produce a turbidity.

As much as 4 per cent. of citric acid has been found in the solutions; if allowed to stand for any length of time, the acid is destroyed. The most favourable temperature is 15°—20° C.; the production of the acid is easily controlled by regulating the temperature, and removed from further action by the addition of chalk, when calcium citrate is thrown down in crusts. A plentiful supply of oxygen is, of course, necessary, as, in order to convert 50 grms. of dextrose into citric acid, 13·3 grms. or 10 litres of oxygen are necessary. These two moulds are widely diffused in nature, being found on a number of vegetable products.

—A. L. S.

Atisine, the Alkaloid of Aconitum Heterophyllum. H. A. D. Jowett. Proc. Chem. Soc. 1896, [168], 158.

THE author has investigated the nature and properties of the alkaloid contained in the roots of the non-toxic *Aconitum heterophyllum*. This alkaloid was examined by Broughton in 1873, who named it atisine, and ascribed to it the formula $C_{46}H_{71}N_3O_5$; it was subsequently examined by Wasowicz and by Alder Wright. The powdered roots were extracted by percolation with a mixture of methyl and amyl alcohol, and from this percolate was obtained the crystalline hydrochloride or hydriodide by the method described in the paper.

Atisine, for which the author adopts the formula $C_{22}H_{31}NO_3$, could only be obtained as a colourless varnish, soluble in alcohol, ether, or chloroform, slightly soluble in water, and insoluble in petroleum ether. Its alcoholic solution is levo-rotatory, $[\alpha]_D = -19\cdot6^\circ$, and though the base is amorphous it yields a series of crystalline salts.

Atisine hydrochloride, $C_{22}H_{31}NO_3 \cdot HCl$, crystallises either from water or from a mixture of alcohol and ether in well-defined prisms, which melt at 296° (corr.), and are freely soluble in water or alcohol, but insoluble in ether. The aqueous solution of the salt is dextro-rotatory, $[\alpha]_D = +18\cdot46^\circ$.

When either the base or its salts are mixed with alkalis or acids in either alcoholic or aqueous solution, no fission of the molecule takes place, but a new base, atisine monohydrate, $C_{22}H_{31}NO_3 \cdot H_2O$, is formed. Neither this base nor any of its salts could be obtained in the crystalline condition.

A preliminary examination of the physiological action of the nitrate by Dr. Cash, showed that the alkaloid is non-toxic, and that its action somewhat resembles that of aconine.

PATENTS.

Aromatic Nitro-Sulphochlorides, Process [Simplified and Shortened] for the Manufacture of. F. von Heyden, Radebeul, Germany. Eng. Pat. 14,276, July 26, 1895.

THIS patent claims the manufacture of nitro-sulphochlorides by the action of chlorosulphonic acid (sulphurylchlorhydric), $SO_2(OH)Cl$, on aromatic nitro-bodies. The reacting substances are mixed together, heated by steam until no more hydrochloric acid is evolved, poured upon ice, and the product filtered off. The mother-liquor contains some nitro-sulphonic acid, which may be converted into nitro-sulphochloride by chlorides of mineral acids.—A. C. W.

Artificial Musk, Impts. in the Manufacture of. Fabriques de Produits Chimiques de Thann et de Mulhouse, Thann, Alsace. Eng. Pat. 15,762, Aug. 21, 1895.

The halogendinitrobutyl xylenes, as

are claimed, together with the processes for their manufacture—(a) By nitration of halogen butyl xylenes, (b) From dinitro-amidobutyl xylene by well-known methods.

—A. C. W.

Pharmaceutical Compounds [Alphyloryacetic - alphyl Esters], Manufacture or Production of. H. E. Newton, London. From "The Farbenfabriken vormals F. Bayer and Co." Eng. Pat. 17,417, Sept. 18, 1895.

THE production of phenoxyacetic phenyl ester and its homologues from phenoxyacetic acid (and its homologues) and phenols, the process for producing these compounds by heating the two substances with phosphorus pentachloride, trichloride, oxychloride, &c., and the bodies themselves, as new articles of manufacture and of medicinal value, are claimed.—A. C. W.

"Artificial Camphor," Impts. in or relating to the Manufacture of, and its Treatment. J. C. Richardson, London. Eng. Pat. 18,297, Oct. 1, 1895.

THIS patent claims the manufacture of an efficient substitute for natural camphor by the action of air and hydrochloric acid gas at a regulated temperature upon turpentine, purification of the crystals so produced by steam distillation in the presence of an oxidising agent (sodium permanganate or bichromate), and final purification by melting in an oil-bath at a temperature not exceeding 175° C., then casting or subliming. The fractional steam distillation of the residual oil from the first process, and its purification in order to separate dissolved camphor-substitute, is also claimed.—A. C. W.

XXI.—PHOTOGRAPHY.

Pyrorrylin, New Solvent for. G. Michaelis. Phot. Wochenbl. 1896, 22, 185.

A SOLUTION of gaseous methyl ether in methyl alcohol is employed, the ether being prepared by distilling about

equal parts of methyl alcohol and sulphuric acid at a moderate heat, cooling the vapours, and passing them through caustic alkali and over calcium chloride into the methyl alcohol. Collodion prepared by this solvent is already employed in America for making collodion emulsion paper, and is also recommended for the wet collodion process. The collodion from this methyl alcohol process does not set so rapidly as that prepared with methyl alcohol, and must therefore be laid in a horizontal position to harden after pouring, otherwise an extremely thin layer will be formed.—C. S.

Pyroxylin, B.P., Notes on. Chas. T. Tyer. Pharm. J. 1896, 109.

THE author's experiments on the manufacture of pyroxylin are confirmatory as to the fact that the presence of moisture in the cotton wool, variation of temperature of mixed acids, time of exposure to the action of mixed acids, and method of washing, all have an effect on the finished product. It was found that the U.S.P. formula gave a better product than the B.P. formula, the B.P. product being of inferior solubility when the yield approached theory. The best drying temperature was found to be 90° F.—A. S.

PATENT.

Photographic Developing Solutions, Impts. in. J. Hauff. Feuerbach, Germany. Eng. Pat. 11,306, May 23, 1896.

THE use is claimed, as developers, of compounds of hydroquinone or pyrocatechol with *p*-phenylene-, *p*-toluylene-, *p*-xylylene-, α - β -naphthylene-, or α - α' -naphthylendiamine and their derivatives, in solution together with alkaline hydroxides or carbonates. The combination takes place on bringing the components together in alkaline solution.—A. C. W.

XXII.—EXPLOSIVES, MATCHES, Etc.

PATENTS.

Gunpowder [in Flat Grains], Improved Process of and Apparatus for Making. P. R. J. Willis, London. From W. E. Peyton, Santa Cruz, Cal., U.S.A. Eng. Pat. 17,935, Sept. 25, 1895.

THE plastic, or gelatinous, explosive to be converted into grains for use in ordnance, or small arms, is squirted into the form of a tube by means of a suitable press. The tube as it leaves the press is slit longitudinally by means of a fixed cutter, and opened out into a flat sheet by means of suitably placed guides.

The sheet thus formed is then passed between grooved rollers, which form it into grains of the desired size and shape.—R. B. P.

Explosives [Ammonium Nitrate], Impts. in the Manufacture of. L. Kelbetz, Wiener-Neustadt, Austria. Eng. Pat. 13,270, June 16, 1896.

AMMONIUM nitrate is mixed with "comparatively high graded fatty acids, or with metallic salts (or soaps) of such fatty acids." A small quantity of charcoal may be added to increase the inflammability of the mixture. 100 parts of ammonium nitrate to from 1 to 20 parts of a suitable fatty acid, or of a metallic salt of such acid, are given as suitable proportions, and stearic, palmitic, oleic as suitable fatty acids.—R. B. P.

Explosives [Ammonium Nitrate], Impts. in the Manufacture of. L. Kelbetz, Wiener-Neustadt, Austria. Eng. Pat. 13,269, June 16, 1896.

AMMONIUM nitrate is mixed with aniline or toluidine oxalate, or both, or with another suitable crystalline compound of an aromatic amine with an organic acid.

The following example is given:—Ammonium nitrate, 100 parts, with from 1 to 20 parts of aniline oxalate.

A small proportion (less than 5 parts) of charcoal may be added in order to increase the inflammability.—R. B. P.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS, ETC.

Gas Analysis, Apparatus for. O. Bleier. Ber. 29, [2], 260–265. (See also this Journal, 1896, 294 and 616.)

1.—*Automatic Measurement of Gases in a state of Saturation with Water Vapour.*—To avoid errors due to the influence of the tension of water vapour on the volume of the gas, it is necessary to keep the latter saturated with the former throughout the analysis, the small film of water left adhering to the wall of the measuring vessel being sufficient. The formation of drops is prevented by reducing the rate of outflow.

With this purpose in view, Orsat's apparatus may be modified as follows (Fig. 1):—A three-way tap, *h*, at the bottom of the measuring vessel *A* (capacity 100 c.c.)

Fig. 1.

connects the latter with the tubing *d*, or the horizontal overflow pipe *b*, through which the water can be run off from *A* in 2–3 minutes. At the upper end of *A*, a tap *h'* communicates with the tube *c* for admitting the gas, and with *r*. The latter is tapped at *h''* and *h'''*, the junctions of the capillaries leading to the absorption vessels *C'* and *C''*, no tap being needed for *C'''*.

It is claimed for this modification that the operation is more speedy and accurate, there being no error to take into account from the solubility of the gas, and no need to empty the tube *r* before each determination, since only the residual gases from the previous test are present; moreover, the taps *h''* and *h'''* prevent the gas from diffusing further in *r* and so escaping absorption.

11. *Apparatus for Gas Titration.*—The apparatus (Fig. 2) consists of a glass sphere, *A* (500–600 c.c.), mounted on an iron frame. At the upper end, *A* terminates in a tube connected by a two-way tap *m*, with a cylindrical funnel *o*, and a capillary tube *p*, and, at the bottom, in a three-way tap *n*. A vertical measuring tube, *B*, graduated to $\frac{1}{2}$ c.c., is connected with *n* by a 75-cm. tube.

A, having been dried, the gas under examination is introduced, through *n* or *p*, according to its density, and allowed to remain a short time under pressure, to attain the prevailing room temperature. After releasing the pressure, the absorption of the gas is effected by introducing the absorbent liquids through *B*, if measured, or through *o* if in unmeasured quantities, the liquids being drawn off at the end of the operation by a vacuum flask *C* attached to *n*, in which vessel they are subsequently titrated. The residual gas may be examined either in the apparatus itself or trans-

ferred to Orsat's apparatus, &c., for absorption or combustion analysis; in the latter event the results must be corrected to the original volume of gas taken.

Fig. 2.

When the apparatus is used for absorption analyses, the gas is measured as described under 1., by the displacement of water, and the absorbent liquid is contained in B, the degree of absorption being shown by the decrease of the liquid in the tube. Under favourable conditions the method is exact to 0.1 per cent.—C. S.

Filter of Cellulose. H. Pottevin. *Comptes rend.* 1896, 123, [4], 263.

The author finds that a paste composed of finely pulverised and sifted cellulose fibres suspended in water, if slowly dried in slabs some millimetres thick, forms a filtering medium capable of replacing porcelain for the arrest of micro-organisms. The slabs must be supported between sheets of sandstone or perforated metal, and may be arranged in batteries like filter presses. Their advantages are cheapness and the property of being easily reduced to paste again and regenerated for use. The results of two experiments are given, showing the capabilities of such a filter. In the first, a slab 2.5 mm. thick arrested all organisms for six consecutive days, under a pressure of about 10 m. of water; in the second, a slab 1 mm. thick broke down on the third day. Water from a reservoir was used.—L. A.

Gas Regulator, A Simple Form of. L. Saarbach. *J. Amer. Chem. Soc.* 1896, 18, 511—513.

The flow of gas is regulated by the motion of a column of mercury, actuated by the expansion of air confined in a bulb. Illustrative cuts are given in the original. The second form shown is suitable for use at high temperatures, being provided with a second bulb and sufficient mercury to furnish a seal sufficient to prevent the escape of the expanded air. The apparatus can be very readily cleaned and refilled, when dirty, and is stated to be only slightly influenced by the daily changes in the atmospheric pressure.—H. T. P.

Fuel, Determination of Heat of Combustion of. W. Hempel. *Zeits. f. angew. Chem.* 1896, 12, 350—352. (See also this Journal, 1893, 179.)

SEEING that the value of a fuel when burned beneath a boiler, or otherwise used in practice, is smaller than is indicated by the result of a calorimetric determination, by the quantity of heat represented by the water formed on combustion and passing away uncondensed, it is desirable to determine the amount of this water and to correct the usual statement of total heat units. When an analysis of

the fuel is made, this can readily be done, but when only a calorimetric determination is contemplated, the arrangement shown in the figure is useful. The device is sufficiently obvious to need but a brief description. A short copper tube *l* is soldered on to the closing cap of the calorimeter

bomb, so as to give communication with the inner cavity. A socket *k* on the other side of the cap serves for the introduction of a thermometer. A drying tube B and a guard tube C attached to *l* completed the arrangement. Before the determination, the well-dried bomb is kept in a desiccator to ensure the absence of casual moisture, and when the combustion is complete, the bomb is connected with the drying tubes and heated with a free flame until all the water is expelled, this being ensured by evacuating the bomb by means of a water-pump, admitting air and again evacuating. Tests on known quantities of water successively admitted to and expelled from the bomb gave satisfactory results.—B. B.

Condenser, A New Form of. R. Walther. *Chem. Zeit.* 1896, 20, 462.

The apparatus shown in the figure is designed, more especially, for use in cases where it is necessary to shake up a flask while it is being heated under an inverted condenser. By its use, this operation can be performed without detaching the flask.

It consists of two tubes, A and BB, of either metal (nickel-plated brass) or glass, one inside the other, and fastened together at the ends, the intervening space being divided into two parts by diaphragms running on opposite sides almost the whole length of the outer tube. The cooling water which flows in at one side, through C, is thus caused to pass downwards to the bottom and ascend, passing out at the opposite side.

The condenser is attached to the distilling flask by means of a stopper K, or is merely placed in the neck of the flask.

The side tube D allows air or other gases to escape when the end A is closed (with a stopper and tap-funnel, for instance). This tube is closed, when the condenser is used in the ordinary manner for distilling purposes, to prevent air from being drawn in.—E. B.

Engler's Viscosimeter, Heating by Means of a Ring-Burner. Holde and Schwarz. *Mitt. Königl. techn. Versuchs. zu Berlin*, 1896, 117—118.

IN the opinion of the authors, Engler's viscosimeter can be satisfactorily heated by the direct application of a burner. The tendency, alleged by Wischin, to overheat the exit tube is negligibly small.—B. B.

INORGANIC CHEMISTRY.—QUALITATIVE.

Ozone, Separation from Hydrogen Peroxide, and Recognition in the Atmosphere. C. Engler and W. Wild. Ber. 1896, 29, 1940.

WHEN a mixture of ozone and hydrogen peroxide vapour is passed over solid chromic acid spread over glass beads, or through a concentrated solution, the hydrogen peroxide is entirely destroyed, but the ozone remains unaltered, though this may not be the case with minute quantities of atmospheric ozone when the chromic acid is but partially reduced. The most certain test for ozone is given by paper soaked in strong manganous chloride solution, which is turned brown by ozone, but not by hydrogen peroxide or nitrous acid, and the brown coloration is changed to blue by guaiacum tincture. The brown coloration given by ammonia does not give the blue with guaiacum. In this test, free halogens, and hypochlorites, &c., must of course be excluded.

—A. C. W.

Gold, A Colorimetric Test for. Carnot. Berg- und Hüttenmann. Zeit. 1896, 55, 215.

IF to a gold chloride solution of known strength, a few drops of arsenic acid be slowly added, and then after some time 2 or 3 drops of dilute ferrous chloride solution and a little hydrochloric acid, a rose-red coloration appears. If too little acid be added, there is a purple precipitate, and if too much, the reaction does not take place and only a bluish tint is produced. 100 c.c. of this solution are mixed with distilled water and zinc added, a coloration varying between red and purple according to the quantity of gold appears and remains a long time. With solutions containing between 0.1 and 1 mgrm., the gold content can be estimated by comparison of the tint.—A. C. W.

INORGANIC CHEMISTRY.—QUANTITATIVE.

Water, Determination of Oxygen in. — Romija. Rec. trav. Chim. des Pays-Bas, 1896, 15, 76.

AN aqueous solution of 1 mol. of manganous chloride, 2 mols. of potassium sodium tartrate, and caustic soda in excess, will absorb the oxygen dissolved in water and become brown. With an excess of manganous hydrate the reaction is complete in 10 minutes, and the oxygen may be estimated by the iodine it liberates from potassium iodide. The test may be performed in a pipette tapped on either side, and having a graduated glass tube (about 1 c.c. capacity) fused on to the upper tap. The water having been introduced, and the upper tube dried, the latter is filled with 1 c.c. of a solution containing 1.12 gm. of manganous chloride and 0.085 gm. of potassium iodide, the said solution being then run into the pipette and an equivalent quantity of water run off through the bottom tap. After shaking up the contents of the pipette, 1 c.c. of a solution (0.1 gm.) of potassium sodium tartrate and an equal quantity of caustic soda solution of the same strength are successively added in the same manner and left for 10 minutes. Finally, 1 c.c. of 25 per cent. hydrochloric acid is run in and the liquid transferred to an Erlenmeyer flask, where the liberated iodine is titrated with thiosulphate. The iodine is directly equivalent to the oxygen originally in solution. In calculating the results, the 4 c.c. of water lost during the addition of the reagents must be taken into account.—C. S.

Potassium, Estimation of. C. Fabre. Comptes rend. 122, 1331—1333.

THE author recommends the following method for saving time in the estimation of potassium as platinumchloride. The potassium platinumchloride, prepared and washed with alcohol and ether in the usual way is treated with boiling water and the solution reduced with magnesium powder (previously washed with alcohol and distilled water). The reduction should take place at about 60° C., and with not too large an excess of magnesium. The action is as follows:— $2\text{Mg} + \text{K}_2\text{PtCl}_6 = 2\text{KCl} + 2\text{MgCl}_2 + \text{Pt}$

The platinum and excess of magnesium are filtered off and the chlorine titrated in the filtrate with decinormal silver

nitrate. Knowing the amount of chlorine it is easy to calculate the corresponding quantity of potassium. A large excess of magnesium, too high a temperature, or too concentrated a solution is apt to give rise to the formation of magnesium oxychloride which would be retained in the precipitate, so it is best in every case to add a few drops of sulphuric acid before filtration, and then to add a slight excess of calcium carbonate to the filtrate. This method is likely to be of use in agricultural laboratories.—J. S.

Potassium Bicarbonate, Use of, in Volumetric Analysis. G. Freyss. Bull. Soc. Ind. Mulhouse, 1896, 250—254.

A NORMAL solution of the salt is prepared. It may be employed to determine:—Alkali hydroxides in admixture with alkali carbonates and coloured impurities; alkali bicarbonates and carbonates, together or singly; the alkali-saturating power of crude phenols (to give the amount of alkali required to dissolve out the phenols present); phenols of known composition in the presence of indifferent oils: of eugenol, for instance, in oil of cloves, &c., or of thymol in oil of thyme.

An example of the method for making the first of these determinations is as follows:—A portion of a solution containing sodium hydroxide, carbonate, sulphate, chloride, and other salts, and of a colour which rendered it difficult to perceive the pink coloration produced in it by the addition of phenolphthalein, was diluted to 10 times its volume. 50 c.c. of the diluted solution were taken, and 100 c.c. of a solution of barium chloride (244 grms. per litre) added, together with a few drops of phenolphthalein solution. Without the precipitate being removed, the standard solution of potassium bicarbonate was then run in, the precipitate of barium carbonate formed carrying down with it the coloured impurities present and making it easy to see the end point of the reaction. The amount of sodium hydroxide in 5 c.c. of the original solution, is obtained by multiplying the number of c.c. required by 0.040.—E. B.

Halogens, Quantitative Determination of the, in Mixtures of their Binary Compounds. A. A. Bennett and L. A. Placeway. J. Amer. Chem. Soc. 1896, 18, 688—692.

THE solution containing the mixed salts is introduced into a distilling flask, 50 c.c. of a 20 per cent. solution of iron alum added and the liberated iodine is then distilled over into 35 c.c. of a 20 per cent. solution of potassium iodide, the amount of iodine in the distillate being determined in the usual way. 35 c.c. of a saturated solution of potassium permanganate are now added to the contents of the distilling flask, together with sufficient water to bring the bulk to about 200 c.c. On continuing the distillation, the bromine is liberated and collected as before. The contents of the distilling flask are then transferred to a beaker, the excess of the permanganate is reduced by ferrous sulphate, with the addition of sulphuric acid, the solution diluted to a definite bulk, in a portion of which the chlorine may be determined by means of silver nitrate.

The method is suitable for rapid technical estimations of bromine or iodine, single analyses occupying from 10 to 15 minutes.—A. K. M.

Sulphates into Chlorides, A New Method of Conversion of. P. Jannasch. Zeits. anorgan. Chem. 1896, 12, 223.

THE sulphate, mixed with 4—5 times its weight of finely powdered anhydrous boric acid, is heated in a platinum crucible until fumes of sulphuric acid cease to come off, which takes about 15—30 minutes. The fused mass is then treated with methyl alcohol which has been saturated in the cold with pure hydrochloric acid gas. On evaporating this mixture with an excess of hydrochloric acid, the boric acid is expelled in the form of its volatile methyl ester, leaving a residue of the chloride of the base present. Or, the boric acid may be more rapidly removed by dissolving the fused mass at once in hydrochloric acid and methyl alcohol, and evaporating. The author states that he has, by this method, transformed into their chlorides, the sulphates of sodium, potassium, and magnesium, and also with similar facility, heavy spar, and some metallic sulphates. The method may be applied with advantage upon silicates after they have been first decomposed by ammonium fluoride.—H. S. P.

Calcium Carbide, Estimation of Sulphides in. F. J. Pope.
J. Amer. Chem. Soc. 1896, 18, 740--741.

A WEIGHED quantity of the calcium carbide is introduced into an Erlenmeyer flask fitted with a stopcock funnel, and connected with two wash bottles containing 150 c.c. of lead acetate solution of known strength. Water is cautiously introduced through the funnel, and when the evolution of acetylene has ceased, dilute sulphuric acid (1:3) is added, and the contents of the flask gently boiled. A current of air is finally passed through the apparatus, the contents of the wash bottles filtered and the lead determined in the filtrate. From the difference between the lead found and that originally present, the amount of sulphur may be readily calculated.—A. K. M.

Fireproof [Fireclay] Materials, Estimation of Alkalis in.
C. Reinhardt. Stahl u. Eisen, 1896, 16, 448.

THREE GRMS. of the material (Fireclay, firebrick, tile, &c.) dried at 100° to 110° C. are moistened with 10 c.c. of water in a platinum dish, and after 40 c.c. of pure fuming hydrofluoric acid and 5 c.c. of concentrated sulphuric acid have been added, the dish is covered with a platinum lid and heated over asbestos for $\frac{1}{4}$ to $\frac{1}{2}$ an hour, until the contents have decomposed. Heating is continued for a further three hours or so (after removing the lid) to drive off the sulphuric acid, silicon and boron also escaping as fluorides. When cold, the mass is treated with 50 c.c. of water, which dissolves everything but the barium, part of the lime, and a small quantity of alumina and silica. The solution is boiled after the addition of a little rosolic acid, and the alumina and iron thrown down by about 10 c.c. of 10 per cent. ammonia, 3 c.c. of hydrogen peroxide being used to oxidise the iron and precipitate the manganese. The liquid being made up to 300 c.c., 200 c.c. (= 2 grms. of substance) are filtered, evaporated, and dried at a red heat in a platinum dish to drive off the ammonia. To the residue, dissolved in 10 c.c. of hydrochloric acid, are added 20 c.c. of water, and, after boiling, 10 c.c. of ammonia and 2 c.c. of ammonium oxalate. At the end of a few hours, filter, evaporate, and heat to redness with a little ammonium carbonate to convert the fusible bisulphates into neutral salts. The residue consists of the sulphates of magnesium, potassium, and sodium, from 2 grms. of substance, together with the impurities in the reagents. The latter must be ascertained by a blank experiment, and, since the impurities are mostly from the defective glass of the bottles, it is advisable to use dry reagents.

To determine the alkalis in the residue, dissolve in 200 c.c. of water, and add to one-half, 10 c.c. of dilute hydrochloric acid, 40 c.c. of ammonia, and 0.5 gm. of sodium biphosphate, filtering off the magnesium precipitate after 12 hours, redissolving it in 10 c.c. of nitric acid, heating to redness and weighing as pyrophosphate. The sodium and potassium are estimated from another portion of the 300 c.c. solution, 75 c.c. of which are heated along with 10 c.c. of dilute hydrochloric acid and precipitated with 5 c.c. of barium chloride solution, the barium sulphate being calculated to potassium plus sodium (in 0.75 gm. of substance).—C. S.

Mortar, The Analysis of. W. J. Dibdin and R. Grimwood.
Analyst, 1896, 197--204.

THE byelaws of the London County Council provide that mortar used under the Metropolitan Management and Building Acts Amendment Act, 1878, shall be composed of "freshly-burnt lime and clean, sharp sand or grit, without earthy matter, in the proportions of one of lime to three of sand or grit; for cement mortar, the proportion of aggregate is increased to 4:1, and burnt ballast or broken brick may be substituted for sand or grit. These proportions are by apparent volume, and it therefore becomes necessary to translate the result of the analysis of the mortar made by weight into the nomenclature adopted in the Act.

The authors have found that average commercial building lime contains 80 per cent. of CaO; hence the percentage of CaO found in a mortar must be increased by one-fourth of its amount to convert it into the corresponding percentage of commercial lime. Further, they state that as, according to their experiments, 17.38 grms. of lime occupy 18.5 c.c. and that 21.13 grms. of broken brick occupy the same

volume, the conversion of a given weight of commercial lime into terms of volume, taking that occupied by an equal weight of broken brick as the unit, may be effected by increasing the value found by one-fourth. Thus a mortar in which 10.89 per cent. by weight of CaO was found, would be calculated to contain $10.89 + \frac{10.89}{4} = 13.61$ per

cent. by weight of commercial lime, i.e., $13.61 + \frac{13.61}{4} = 17.0$ per cent. of commercial lime by apparent volume; in the same mortar, after allowing for moisture and soluble matter from the brick used as aggregate, the percentage of broken brick was found to be 48.75 per cent. by weight. The translation of weight into volume (adopting the volume of a given weight of broken brick as the unit) has already been accomplished by the use of the factor 1.25 for the lime above. Consequently the figures for lime and brick may be directly compared. These are 17.0:48.75 or 1:3 nearly, corresponding with the intended composition of the mortar. Similarly with cement mortar, the authors state that "average Portland cement will contain from 17 to 20 per cent. of soluble silica," and that equal volumes of washed and dried sand and of Portland cement of sp. gr. 3.15 were found to weigh 21.7 and 19.3 grms. respectively, whence they deduce that a sample of cement mortar containing 3.25 per cent. of soluble silica (that serving as the criterion), would contain 18 per cent. of cement, i.e., 19.25 per cent. by volume; seeing that in the same sample the sand and grit equalled 67.34 per cent., the ratio of cement to sand was 1:3.5.

The following is an outline of the method of analysis used by the authors:—10 grms. of the mortar are dried on the water-bath, for the determination of moisture; error caused by absorption of CO₂ is negligible. 10 grms. are mixed with hydrochloric acid of 10 per cent. strength, allowed to stand for one minute, the solution decanted together with the fine earthy matter in suspension. Washing is carried on by decantation until all the supernatant liquor at the end of one minute's subsidence is clear. The clean, washed sand and grit or broken brick is dried and weighed; the earthy matter in the decanted liquid is filtered off and weighed; a known fraction of the filtrate is taken for the estimation of silica and bases. The sample taken for moisture after weighing, is ignited at a dull red-heat, insufficient to decompose the carbonate, and the loss on ignition so found is corrected by moistening the ignited mortar so as to hydrate the lime, drying the product and weighing again.—B.B.

Monazite Sand, The Analysis of, and the Estimation of Thoria. C. Glaser. Chem. Zeit. 1896, 63, 612.

IN devising a process for the analysis of monazite sand, the author found that a useful method could not be constructed from published sources of information. The solution from which the rare earths are to be precipitated as oxalates must not be very acid, as otherwise traces of thoria remain in solution. The author could not obtain complete separations of thoria from oxides of the cerium group by means of sodium thiosulphate or by fractional precipitation with weak ammonia. Where small quantities of cerite earths have to be separated from thoria, this may be done by adding excess of ammonium oxalate to the boiling, slightly acid solution, and filtering off the precipitated cerium oxalates; the thorium oxalate remains in solution and crystallises out, on cooling the filtrate. Experiments giving satisfactory results are quoted to show that a good separation may be effected by precipitating the cerite oxalates by means of ammonium oxalate in boiling solution in presence of ammonium acetate, the thorium oxalate remaining dissolved and being recoverable from the filtrate by precipitation with ammonia. It is best not to add the ammonium acetate until the oxalate precipitate has just formed, otherwise the latter is apt to pass turbid through the filter. The author states that if thorium oxalate, which has been kept in solution by ammonium acetate, is precipitated by ammonia, then after most careful washing and redissolving in mineral acid, even after ignition, it can no longer be completely precipitated in almost neutral solution by ammonium oxalate. The appended table shows the principal reactions of the rare earths.

BEHAVIOUR OF THE EARTHS WITH DIFFERENT REAGENTS.

—	KOH or NaOH.	K ₂ CO ₃ or Na ₂ CO ₃ .	K ₂ SO ₄ or Na ₂ SO ₄ .	Na ₂ S ₂ O ₃ .	NH ₄ HO.
Al ₂ O ₃	Precipitates, soluble in excess.	Precipitates.	Forms alum.	Precipitates in almost neutral solution on boiling.	Precipitates.
Be ₂ O ₃ or BeO ...	Precipitates, soluble in excess; re-precipitates on boiling or diluting.	Precipitates, difficultly soluble in large excess; also on passing in CO ₂ .	No precipitate: no formation of difficultly soluble double salts.	No precipitate.	Precipitates, insoluble in excess.
ZrO ₂	Precipitates, insoluble in excess.	Precipitates, somewhat soluble in excess; is precipitated therefrom by NH ₄ HO.	Soluble double salt, hot; precipitates basic salt on cooling (insoluble in HCl).	Precipitates hydrate mixed with S.	Do.
Gadolinite earths	Do.	Precipitates, soluble in excess. In a few hours precipitates insoluble double salt (Y).	Soluble: precipitates in concentrated solutions, soluble in aqueous solution of K ₂ SO ₄ . (Y does not precipitate at all.)	?	Do.
ThO ₂	Do.	Precipitates, soluble in excess; not precipitated therefrom in cold by NH ₄ OH. Dim on warming, clear again on cooling.	Forms double salt with K ₂ SO ₄ , difficultly soluble in water, insoluble in saturated aqueous K ₂ SO ₄ . Sodium compound much more soluble.	Precipitates, but not quite completely, even on boiling concentrated solutions.	Precipitates, insoluble in excess; precipitates on fractionating before cerium group (Crookes).
CeO	Do.	Precipitates, somewhat soluble in excess.	Double salt, insoluble in solution of K ₂ SO ₄ .	No precipitate.	Precipitates (after ThO ₂), insoluble in excess.
Ce ₂ O ₃	Precipitates, flesh-coloured with excess.	Precipitates, almost insoluble in excess.	..	Do.	Like KOH.
La ₂ O ₃	Precipitates, insoluble in excess.	Do.	Difficultly soluble double salt.	Do.	Do.
Bi ₂ O ₃	Do.	Do.	Do.	Do.	Do.
—	(NH ₄) ₂ CO ₃ .	(NH ₄) ₂ S.	NH ₄ Cl.	(NH ₄) ₂ C ₂ O ₄ .	NH ₄ C ₂ H ₃ O ₂ .
Al ₂ O ₃	Precipitates.	Precipitates hydrate.	Precipitates solution in NaOH.	Does not precipitate.	Precipitates basic salt on boiling neutral solution.
Be ₂ O ₃ or BeO ...	Precipitates; easily soluble in excess; precipitates on boiling. Not certain for separating from Al ₂ O ₃ .	Do.	Hydrate dissolves on long boiling, with loss of NH ₄ HO.	No precipitate; easily soluble double salt.	?
ZrO ₂	Precipitates; soluble in large excess; precipitates on boiling.	Do.	No precipitate.	Precipitates, soluble in excess.	?
Gadolinite earths	Precipitates, easily soluble in excess. After a few hours precipitates insoluble double salt (Y).	Do.	?	Precipitates E. from boiling acid solutions as clear red sandy powder.	?
ThO ₂	Precipitate easily soluble in excess.	Like NH ₄ HO.	No precipitate.	Precipitates, soluble in excess on boiling; precipitates on cooling.	No precipitate; prevents entirely precipitation by (NH ₄) ₂ C ₂ O ₄ ; partly precipitated therefrom by HCl; precipitated as hydrate by excess of ammonia.
CeO	Do.	Do.	Do.	Precipitates, even in rather acid solution. Somewhat soluble in large excess of acid.	Does not prevent precipitation.
Ce ₂ O ₃	Precipitates, soluble in large excess; precipitates on boiling.	Do.	Do.	Do.	Do.
La ₂ O ₃	Like NH ₄ HO; absolutely insoluble in excess.	Do.	Do.	Precipitates in neutral or ammoniacal solution (?).	Do.
Bi ₂ O ₃	Precipitates rose-red, quite insoluble.	Do.	Do.	Precipitates white to pale reddish, almost insoluble in dilute acids.	Do.

Analytical Process.—Decompose 2 grms. of the finely ground sand by continued heating with strong sulphuric acid or by fusing with potassium acid sulphate. The author prefers to fuse only such residue as remains insoluble in sulphuric acid. Transfer the mixture slowly to ice-cold water, when everything dissolves except silica and tantalum acid. Evaporate the residue twice with H₂F, moisten with sulphuric acid, evaporate to dryness, and ignite strongly; the loss in weight gives silica.

Any residue in the crucible is treated with hot sulphuric acid or fused with potassium bisulphate, and whatever now remains insoluble in ice-cold water is put down as *tantalum acid*. Unite the two solutions, and saturate, first hot and then in the cold, with sulphuretted hydrogen, to precipitate *titanic acid, lead, &c.* From the filtrate, boil off the sulphuretted hydrogen, neutralise most of the free acid by ammonia, and add to the boiling solution excess of hot ammonium oxalate solution. For 2 grms. of the sand use 100 c.c. of cold, saturated solution. Thoria and oxides of the cerium group are precipitated as oxalates, and are filtered off.

In solution are phosphoric acid and oxides of iron, aluminium, manganese, beryllium, yttrium, zirconium, and calcium. Add ammonia and filter off the metallic phosphates (preserving the filtrate). After igniting, fuse with fusion mixture, extract with water, and add the filtrate to the one just mentioned. Dilute to a certain volume, and determine *phosphoric acid and alumina* in an aliquot part. Dissolve the carbonates remaining on the filter-paper by means of sulphuric acid, add ammonia, and estimate *lime* in the filtrate. Dissolve the precipitated hydroxides in a little hydrochloric acid, neutralise as nearly as possible with ammonia, and pour into a sufficient excess of solution of ammonium carbonate containing a few c.c. of ammonium sulphide. Filter off the precipitated *iron, manganese, &c.*, and separate them by the usual processes. In the filtrate are the zirconia, yttria, and beryllia, to separate which boil the ammonium carbonate solution for an hour, whereby they are precipitated quantitatively. Redissolve in hydrochloric acid, boil, cool, and add excess of sodium hydrate. Filter off the precipitated *zirconium and yttrium hydroxides*, and separate them as usual by crystallisation of the zirconia as double sulphate with potassium sulphate. The *beryllia* is precipitated from the filtrate by boiling it for an hour.

The precipitated oxalates of thorium and the cerium group are separated as follows:—Ignite, dissolve in sulphuric acid as usual, neutralise most of the free acid by ammonia, add to the boiling solution excess of boiling ammonium oxalate solution, and as soon as the oxalates of the cerium group have mostly formed, add a few c.c. of ammonium acetate solution, and allow to stand overnight. Filter and precipitate the *thoria* from the filtrate by ammonia, and weigh. *Ceria* is easily separated from *lanthana* and *didymia* by the known process of passing chlorine into the suspended hydroxides, freshly precipitated by caustic soda.

The following analyses were made by this scheme, the second and third samples being honey-yellow monazite sand from North Carolina:—

	1.	2.	3.
	Per Cent.	Per Cent.	Per Cent.

—H. B.

Copper, the Cyanide Method of Determination of; Effect of Variation of Acid in. F. N. Flynn. Eng. and Mining J. 1896, 62, 51.

C. and J. J. Bergruer, in their Text-Book on Assaying, state that varying the amount of nitric acid in the cyanide determination of copper does not affect the results, as the decrease in the amount of cyanide required, due to the lessening of the free ammonia, is balanced by the increase due to the formation of ammonium nitrate.

This statement is contradicted by the author, who gives the results obtained by him:—

	C.c.	C.c.	C.c.	C.c.
Nitric acid added.....	None	3.0	5.0	10.0
Cyanide required.....	33.3	34.9	35.4	36.4

The author concludes from these experiments that if the cyanide solution be standardised with a solution of copper nitrate, without the addition of nitric acid equal to the amount used in the regular assay, the results obtained will be very inaccurate.—A. S.

Manganese, Determination of, in Steel; Sources of Error in Volhard's and Similar Methods. G. Auchy. J. Amer. Chem. Soc. 1896, 18, 198—511.

It is shown that:—

1. The accuracy of Volhard's method largely depends on the conditions under which the neutralisation with zinc oxide is effected.

2. High results are obtained by titrating in nitric acid solution.

Stone's modification (in which the evaporation with sulphuric acid, after solution in nitric acid, is omitted) is, however, preferred by the author, on account of its simplicity, and the short time required for a determination; and in the following scheme, the precautions to be adopted are accentuated:—

Dissolve 3.3 grms. of drillings in 50 c.c. of nitric acid (sp. gr. 1.2), transfer the solution to a 500-c.c. flask, neutralise two-thirds of the acid with sodium carbonate, cool, add zinc oxide emulsion until the solution stiffens, avoiding an excess. Dilute to about 400 c.c., mix, allow to stand until the precipitate of ferric hydrate settles (the supernatant liquid should be colourless), and now, and not before, add a considerable excess of zinc oxide. Dilute to the mark, mix, transfer to dry beaker, mix again, allow to settle, and decant off 250 c.c. of the clear liquid, and titrate at a boiling temperature with permanganate (strength 0.0056). After making allowance for the impurities present in the soda and zinc oxide used, the c.c. of permanganate consumed divided by 10 = per cent. of manganese in the sample. Deduct 0.02 per cent.

(See also Sutton's Volumet. Analysis, 7th edit. 1896, page 232.)—H. T. P.

Manganese, Estimation of, in the Presence of Phosphoric Acid. G. Viard. Bull. Soc. Chim. 1896, 15—16, [15], 973—975.

The presence of phosphoric acid vitiates Hannay's method of estimating manganese, since instead of the peroxide, the tribasic phosphate, $Mn_2O_3 \cdot P_2O_5 + 3H_2O$, is precipitated, notwithstanding that the liquid is strongly acid, when the proportion of phosphoric acid exceeds 1 P to 1 Mn. When the ratio is lower—as in the case of manganiferous cast iron—the precipitate will consist of a mixture of peroxide and phosphate, and will, moreover, be incomplete, so that incineration and estimation as pyrophosphate would not yield accurate results, even were it not that the phosphate readily escapes through the filter during the washing.—C. S.

Copper, Crude; The Analysis of. F. Jean. Ann. Chim. 1896, 1, 185.

10 grms. of filings are treated with a dilute mixture of nitric acid and sulphuric acid of 66° B., and the solution is evaporated to dryness; the residue is taken up with water and alcohol, and filtered. The insoluble portion, which consists of lead sulphate and silica, and dioxide of tin, is

digested with a solution of ammonium carbonate, which converts the sulphate of lead into carbonate of lead, which is then dissolved out by nitric acid, and the lead estimated in the usual way. The silica and dioxide of tin, which are not dissolved by the nitric acid, may then be fused with alkaline carbonate to convert the tin into stannate, from the solution of which the tin may be separated by metallic zinc.

The main filtrate, containing the copper and other metals, is boiled to expel the alcohol, and is then poured into an alkaline solution of sodio-potassium tartrate, heated to the boiling point, and the copper reduced by a solution of glucose. When the precipitation of the copper is complete, the flask is closed, rapidly cooled, and the volume of the liquid made up to one litre with boiled-out water. After allowing the cuprous oxide to settle, 500 c.c. of the clear liquid are taken out, an excess of polysulphide of sodium added, and the liquid warmed at 80° for half an hour. The metals of the ammonium sulphide group are thereby precipitated, whilst arsenic and antimony remain in solution. In the precipitate, iron, zinc, and manganese are separated from nickel and cobalt in the known way, by treating the sulphides with dilute hydrochloric acid. The sulphides of nickel and cobalt are afterwards dissolved by nitro-hydrochloric acid, and then precipitated with bromine and alkali. Arsenic and antimony are precipitated from the solution in the usual way.

The author determines carbon and silicon by dissolving the copper filings in ferric chloride solution.

He determines the oxide of copper present by treating 5 grms. of filings in a flask provided with a Bunsen's valve, with hydrochloric acid, some pieces of marble being also placed in the flask; the solution is then poured off, the excess of acid expelled by evaporation, and the copper in solution precipitated by means of zinc; the precipitated copper is then dissolved in dilute sulphuric acid, and its amount determined by titration with stannous chloride solution, according to Weil. The total amount of copper in the sample is determined either electrolytically or by titration with stannous chloride.—H. S. P.

Mercury, General Method for the Estimation of. M. G. Deniges. *Bull. Soc. Chim.* 1896, **15**—16, 862—871.

WHEN a mercuric salt is brought into contact with an excess of potassium cyanide solution, the compound—

is formed, and if to this solution, ammonia and potassium iodide as indicator, are added, then on running in decinormal silver nitrate the following decomposition takes place:—

and the moment this decomposition is complete, the slightest excess of silver nitrate produces an opalescence due to silver iodide.

The method of conducting the estimation is therefore as follows:—10 c.c. of ammonia are added to the solution containing the mercuric salt, and an excess, say 10 c.c., of potassium cyanide equivalent to the decinormal silver nitrate. After a further addition of five or six drops of a 20 per cent. solution of potassium iodide, the decinormal silver nitrate is run in until a permanent opalescence is produced. If 10 c.c. of potassium cyanide and q c.c. of decinormal silver nitrate were used, then $10 - q = a$ represents the amount of decinormal silver nitrate corresponding to the mercury in the solution. For very accurate work, however, this number a must be subjected to a slight correction on account of the decomposition in the sense of the above equation, scarcely ever being quite complete. A certain, always very small, quantity of the double cyanide remains undecomposed, and this small quantity appears to increase slowly with the amount of potassium cyanide used.

The author gives the following rules for performing the correction:—(1) When a lies between 0 and 5.5, then the true titre x is found thus: $x = a \times 0.96$. (2) When a exceeds 5.5 and is less than 9.5, then $x = (a \times 1.04) - 0.45$. Hence the amount of mercury in the solution examined is obtained by multiplying x by 0.020 gm.

The method is of very general application, and is said to be independent of the state of acidity or alkalinity of the mercurial solution, of its oxidising power, its coloration and dilution, and it is possible to conduct the method in the presence of the strong mineral acids, especially HCl and HNO₃. It is therefore likely to be of use in the estimation of mercury contained in drugs and disinfecting solutions, and for the determination of tannins, alkaloids, albuminoids, and in general of all substances capable of forming definite compounds with mercury, e.g., thiophene, sulphourea, mercaptans, and simple or compound ammonias.—J. S.

Bismuth Sulphide, Solubility of, in Sodium Sulphide [Estimation of Small Percentages of Bismuth in Alloys]. T. B. Stillman. *J. Amer. Chem. Soc.* 1896, **18**, 683—684.

THE author finds that, contrary to the usually accepted statement, bismuth sulphide is appreciably soluble in sodium sulphide solution, and consequently the employment of the latter for the separation of bismuth from antimony, arsenic, and tin, according to the method frequently adopted, cannot be depended upon, the method being altogether untrustworthy when bismuth is present in small amount, as, for instance, in "magnolia metal."—A. K. M.

"Insoluble" Phosphoric Acid contained in Mixed Fertilisers, and derived from Bones and the like, and from Rock Phosphates respectively. A. P. Bryant. *J. Amer. Chem. Soc.* 1896, **18**, 491—498.

Rare mineral phosphates, being specifically heavier than bone and other organic phosphates, the author effects the separation of the former from the latter in mixed fertilisers by the aid of a liquid of suitable density. This is prepared by dissolving 75 grms. of potassium iodide and 100 grms. of mercuric iodide in 350 c.c. of warm water, and concentrating the solution (to about 100 c.c.) until its specific gravity is 2.26 at 15.5° C.

Process.—2 grms. of the sample are placed in a glass tube, the lower end of which is tied over with filter paper and cloth, and washed with 200—250 c.c. of hot water to remove soluble phosphates. The "separator" used consists of a short tube (7 cm. \times 1½ cm.), sealed at one end, and connected by rubber to a longer tube (20 cm.). To this contrivance the washed and dried phosphate is transferred and well shaken with 15—20 c.c. of the separating liquid. Particles adhering to the side of the tube are then washed down with a jet of the liquid, and after 5 minutes the lower tube is smartly tapped and the floating matter stirred up to facilitate the separation of the heavy from the light constituents. When the liquid is clear (in about 1 hour), the rubber tube is compressed by a screw-clamp, and the short tube containing the heavy (mineral) portion removed. The light (bone, &c.) particles remain in the upper tube. The fractions are thoroughly washed (the first washings should be preserved and again concentrated for future use) and the "citrate insoluble" phosphoric acid determined in each in the usual way. Test analyses made with mixtures of known composition yielded satisfactory results.

—H. T. P.

ORGANIC CHEMISTRY.—QUALITATIVE.

Petroleum, Application of the Acid Test. Trudy bak. *otd. imp. russk. techn. obschtsch.* 1896, **11**, 181.

THE Committee appointed by the Baku Section of the Russian Technical Society to examine the new Petroleum Testing Regulations formulated by the Government, have reported that sulphuric acid of the prescribed density (1.53) is unsuitable for testing petroleum, the colour of the acid extract being irregular, and not sufficiently decisive in gradation. On the other hand, sulphuric acid of 1.73 sp. gr. being found to give concordant results with all grades of petroleum and at all temperatures between 16° and 32° C., it is recommended that this strength of acid should be used in the proportion of 40 parts by volume to 100 of oil, the mixture being shaken up in a stoppered glass vessel for two minutes, and the acid layer removed and compared with normal solutions of Bismarck brown. The standard solutions are 10 in number, and are graduated

so that the lightest (No. 1) contains 0.0005 per cent. of colouring matter, and the darkest (No. 10) 0.005 per cent., the intermediate shades differing from each other by 0.0005 per cent. The degree to which the oil has been refined is expressed by the number of the solution corresponding to the colour of the acid extract, and the maximum effect in the case of ordinary petroleum distillate is found to be produced by the use of 0.75 per cent. of 66° B. sulphuric acid. Since few of the commercial petroleum examined fell below the limits 1 to 8, the latter shade is recommended as the outside limit for merchantable petroleum.

The Committee report adversely on the Hübl iodine test as proposed by Hirsch, the results depending on the nature of the petroleum rather than on the degree of acid purification. For example, petroleum from the "cracking process" always has a high iodine number on account of the unsaturated hydrocarbons formed in the distillation.

—C. S.

Rape-Seed Meal as an Adulterant of Mustard and Linseed Meals, &c., Test for. A. Jaworowski. Pharm. Zeit. Russl. 1896, 35, 360.

The presence of rape in mustard and linseed meals may be detected in the following manner:—A mixture is made of 10 grms. of common salt, 20 grms. of water, and 0.3 grm. of hydrochloric acid, and heated to 70°, and, after addition of 2–3 grms. of the meal, heated to boiling. After cooling and filtering, free acid is removed by sodium bicarbonate, and the solution divided into two parts. To one part, two or three drops of potassium ferriyanide solution (1 per cent.) are added; the liquid obtained from pure linseed meal remains unaltered by the addition of the bicarbonate and ferriyanide; that from mustard seeds acquires a yellow coloration with sodium bicarbonate, which is not altered by the ferriyanide—at least, not in the first minute. But if the sample contain 5–10 per cent. of rape seed, the liquid is coloured yellow by sodium bicarbonate, and, on addition of potassium ferriyanide, turns brownish, reddish, or violet.—A. C. W.

Sugars, New Hydrazones of the [Separation of Sugars]. A. von Eckenstein and C. A. Lobry de Bruyn. Rec. Trav. Chim. des Pays-Bas, 1896, 15, 97.

OTHER hydrazines than that of phenyl can be employed for the separation of sugars, the hydrazones being prepared in the same manner. For example, methylphenyl hydrazine serves to isolate galactose, and glucose may be separated from fructose by benzyl- and naphthylhydrazine. Melibiose forms an allylphenylhydrazone, insoluble in water and decomposable by benzaldehyde into a crystalline sugar, probably pure melibiose. In addition to differences in solubility, these hydrazones are to some extent characterised by differences in specific rotatory power.—C. S.

Cocaine, Detection of Eucaine in. G. Vulpius. Pharm. Central-II., N.F., 1896, 17, 295.

0.1 GRM. of the cocaine hydrochloride to be examined is dissolved in a graduated cylinder in 50 c.c. of water and two drops of ammonia added. If the sample be pure, the solution will remain perfectly bright for at least one minute, and will remain transparent, although after a time crystals of cocaine may separate. In presence of 2 per cent. of eucaine a decided milk-white opalescence is immediately produced, which disappears on addition of 10 c.c. of water. With 5 per cent. of eucaine, the addition of 20 c.c. of water becomes necessary to render the liquid clear; and progressively more water is required in proportion to the percentage of impurity present.—H. T. P.

Formo-Gelatin, Detection of Unaltered Gelatin in. G. Ronyn. Pharm. Weekblad. 33, [1], 1896.

0.5 GRM. of the sample is mixed with 10 c.c. of water and heated for 10 minutes in the water-bath with frequent shaking. The mass swells considerably, but particularly so in the presence of unaltered gelatin, which dissolves in the

liquid. If the liquid be now passed, whilst hot, through a dry filter, it will congeal on cooling, if gelatin be present; the separation of the latter may be accelerated by placing the filtrate in a freezing mixture and then allowing it slowly to melt.

0.5 GRM. of the sample is mixed with 5 c.c. of water and 1 c.c. of aqueous soda; the mass swells considerably, but much more strongly in the presence of unaltered gelatin. If now a mixture be added of 2 c.c. of normal silver nitrate solution and 0.5 c.c. of ammonia, the mass should begin to darken within one or two minutes, and after five or ten minutes the liquid should have acquired a violet-brown colour. If much free gelatin be present the colour makes its appearance more slowly, and assumes a pure brown shade without any violet. Pure gelatin does not colour until after the lapse of a few hours.

If formo-gelatin, even when quite pure, be treated with boiling water, dissociation sets in, and the filtrate gives with copper sulphate and aqueous potash the biuret reaction. In conclusion, the author opposes the use of a preparation containing free gelatin, as this diminishes its antibacterial properties.—L. de K.

ORGANIC CHEMISTRY.—QUANTITATIVE.

Petroleum, Estimation of the Content of Burning Oil by the Distillation Test. R. Zoloziecki. Chem. Zeit. 20, [67], 645–648.

SEEMING that in practice it is customary to group petroleum distillates according to specific gravity rather than boiling point, the author proposes to follow the same rule in the distillation test in order that the results of the two may be comparable. To this end he employs the still described by Wischin (this Journal, 1895, 1038), but with certain modifications, such as reducing the size to about one-half—to hold 1,000 grms. instead of 2 litres—shortening the jacket, so that it only encloses two-thirds of the still, and doubling the height of the ascending tube, the branch tube leading to the condenser being attached half-way up. The heat is regulated so that the drops of distillate flow quickly one after another from the condenser, one drop forming before the preceding one has quite completed its descent. The upper limits of specific gravity are the most important, and, since the quantity of liquid is so small that ordinary means of determining the specific gravity are inapplicable, a series of mixtures of alcohol and water are employed, ascending in density from 0.860 to 0.875. The specific gravity of the distillate is determined by allowing a drop to fall into the test mixtures and observing its comparative density. This method cannot be adopted for the lower limits, so for these the boiling point is taken as a criterion, 125° to 130° C. being adopted as indicating approximately the advent of burning oil in the distillate. For greater accuracy, the limit should be fixed at 150°, and the product supplemented by the residue from the redistillation of the crude benzine boiling below that temperature.

In order to ensure that all the burning oil has come over, it is advisable to continue collecting the distillate until the specific gravity, after attaining 0.865 to 0.870, begins to decrease again as the result of "cracking." If it be desired to know the proportion of decomposable constituents in the oil, the succeeding fractions, until the specific gravity again increases, may be collected, weighed, and mixed with the burning oil. The quality and density of the products of cracking will vary with the origin of the crude oil and the method of distillation, but their weight may be obtained as described above.

In determining the specific gravity, care is necessary to prevent the acid-water formed during distillation from mingling with the oil drops tested, which may be accomplished by having the outflow pipe of the condenser of glass, the milky-looking condensed water being then readily discernible.

The following estimates of the yield from crude oils, based on the foregoing distillation tests, and compared with the results obtained by the Engler-Kissling fractional distillation of the same oil, may be taken as typical.

Crude Oil.	Fractional Analysis.	Estimate of Yield.			
		Per Cent. (Weight).	Per Cent.	Sp. gr.

Petroleum, Determination of Sulphur in. Aufrecht.
Pharm. Zeit. 1896, **41**, 469.

Good petroleum should not contain more than 10—15 mgrms. of sulphur in 100 c.c. To 50 c.c. of the petroleum, 0.5 gm. sodium bicarbonate is added, and the mixture distilled at the rate of 40—50 drops a minute, until about 5 c.c. are left. The residue is placed in a large porcelain dish and repeatedly washed with ether; after spontaneous evaporation of the latter, about 0.5 gm. of sodium is added in small pieces, the whole evaporated over a small flame to a syrup, and then ignited, with the gradual addition of ammonium nitrate, until the ash is quite white. The residue is extracted by very dilute hydrochloric acid, and the sulphuric acid estimated in the filtrate in the usual manner.—A. C. W.

Paraffin in Petroleum, Estimation by ZALOZIECKI'S Method.
K. W. Charitschkow. Trudy bak. otd. imp. russk. techn. obshch. 1896, **11**, 204.

The author finds that the quantity of the alcoholic mixture recommended by ZALOZIECKI for dissolving the higher fractions of the oil is insufficient, 60 volumes being sometimes necessary instead of 20, the actual amount being in direct ratio to the high-boiling constituents present in the oil. The use of large quantities of solvent, however, detracts from the delicacy of the method by preventing the complete deposition of the paraffin.—C. S.

Phenol, Methods for the Quantitative Estimation of.
G. Frerichs. Apoth. Zeit. 1896, **11**, 415.

The author has made a comparison of the known methods. He finds Beckurt's method (Arch. Pharm. 1886, 224, 561; this Journal, 1886, 546—547) to be the best. It yielded the most reliable results both with pure phenol and with phenol compounds. The method consists in acting upon the phenol to be estimated with a known quantity of bromine and then determining the excess of bromine by adding potassium iodide and titrating with $\frac{N}{20}$ sodium thiosulphate; from the quantity of bromine which has been required to form tribromophenol the quantity of phenol is calculated from the equation $C_6H_5OH + 6Br = C_6H_2Br_3OH + 3HBr$.—H. S. P.

Resin Oil in Fatty Oils, Detection of. P. Cornette.
Ann. Pharm. 1896, **2**, 240.

Ten grms. of the suspected oil are saponified with alcoholic caustic soda, the soap is dissolved in warm water, and an excess of a concentrated solution of sodium chloride added. This throws down the fatty acid soaps, leaving sodium resinate in solution. After filtering cold, and washing with salt water, the filtrate, which must be clear, is treated with sulphuric acid in excess, whereupon the resin acids separate in globular form, imparting a milky appearance to the liquid, and, subsequently setting and rising to the surface. A slight turbidity is sometimes obtained with pure linseed oil, but cannot be mistaken for the copious precipitate of resin acids.—C. S.

Hübl [Iodine] Residues, Recovery of Iodine from.
K. Dietrich. Pharm. Central-Bl. N.F. 1896, **17**, 361.

The accumulated residues from Hübl's iodine absorption determinations are evaporated in a porcelain dish until the chloroform has been expelled as far as possible, and they are then made strongly alkaline with caustic potash solution, after which the evaporation is continued to dryness. The

dry mass is then treated with water, which extracts the salts of iodine, the potassium and sodium chlorides, the potassium formate, and the saponified fats, leaving an insoluble residue of mercuric sulphide. On evaporating this solution of the extracted salts as it becomes concentrated, the soap is precipitated, and the evaporation is continued until no more soap separates out, when the liquid is filtered, and a 15 per cent. solution of ferric chloride is then added to the filtrate with constant stirring, until the precipitation of the iodine is completed. The iodine is then separated by filtration, washed, dried by pressure, and reconverted into Hübl reagent.—H. S. P.

Maltose, Determination of, in Worts. L. Braun. Zeits. ges. Brauw. 1896, **19**, 241.

The determination of apparent maltose in worts by means of Fehling's solution is investigated, and the influence of varying experimental conditions determined. To test the influence of the vessel in which the reduction is effected on the results, covered and uncovered dishes and beakers of various forms and dimensions were employed. In addition, experiments were made in currents of oxygen, hydrogen, and air, respectively, and at different pressures. From the results, it is concluded that concordant results can only be obtained by adhering strictly and throughout to a uniform *modus operandi*.—H. T. P.

Calcium Acetate, Analysis of Commercial. E. Barillet.
Rev. Chim. Industr. **7**, [79], 197—201. (See this Journal, 1896, 584.)

The ordinary manner of expressing the total acidity in commercial acetates of calcium, viz., as acetic acid, is inaccurate, since it gives no indication of the proportion of the higher acids of the fatty series present, but simply includes them with the acetic acid. It being important, for various technical operations, to know the percentage of these impurities, and their solubility in water preventing their separation in the method of analysis given by Fresenius, the author experimented on the separation of the barium salts of the fatty acid series by means of absolute alcohol, and found that 100 grms. of that solvent will dissolve respectively 0.0055 gm. of the formate, 0.0284 gm. of the acetate, 0.2610 gm. of the propionate, and 1.1717 grms. of the butyrate of barium. He therefore proposes to make use of this relative solubility by treating the distillate, obtained in the ordinary method of analysis, with boiling absolute alcohol, throwing down the barium as sulphate, and deducting from the total the weight corresponding to the amount of barium acetate soluble in the quantity of alcohol employed; the remainder gives the amount of barium in combination with propionic and butyric acids, the amount of formic acid being so minute as to be disregarded.

In the sample analysis given, 5.0312 grms. of calcium acetate were distilled with phosphoric acid, the distillate saturated with baryta, and the residue left on evaporation, triturated with 800 grms. of absolute alcohol, boiled, and precipitated by sulphuric acid. This treatment yielded 0.3900 gm. of $BaSO_4$, 0.2072 gm. of which represented the barium acetate dissolved in the 800 grms. of alcohol. The remainder, 0.1828 gm., corresponds to the homologous acids, and is equivalent to 2.46, to be deducted from the result of the total acidity determined and expressed in the usual manner as calcium acetate.—C. S.

Glycerol in Wine and Beer, Determination of, by the Index of Refraction. L. Sostegui. Staz. Sperim. Ital. 1896, 318—322.

The glycerol is extracted in the usual way and made up to a definite volume with water; the index of refraction of the solution is determined and also that of pure water. The difference between the indices, calculated to six decimals and divided by 0.00125 will give the percentage of glycerol in the solution.—A. L. S.

Cream of Tartar, Commercial; Composition and Analysis of. A. H. Allen. Analyst, 1896, **20**, 174—182; and 209.

Calcium tartrate is an invariable constituent of cream of tartar when the latter has been prepared from *argol* by

boiling with water, filtering, and crystallising, and the amount is largely dependent on the proportion of water used. In practice, 9 or 10 per cent. is the usual maximum quantity of calcium tartrate, and any material excess over this amount points to adulteration. In crude tartar, especially when derived from plastered wines, sulphates accompany the high percentage of calcium tartrate. In one sample of cream of tartar the author found 20 per cent. of calcium sulphate, apparently added as an adulterant.

In the test given by the British Pharmacopœia of 1885, the soluble ash should require for neutralisation an amount of acid corresponding to 92.15 per cent. of potassium hydrogen tartrate. The author recommends the use of 5 grms., the soluble ash from which should neutralise not less than 24.4 c.c. of normal acid. The standard of purity required by the United States, German, and Japanese Pharmacopœias for cream of tartar has of late years been raised, and is now 99 per cent., and the British standard being so much lower than this, there is, it is said, no excuse for the sale of cream of tartar containing, as in a recent Belfast case, 17.93 per cent. of calcium tartrate.

Much of the cream of tartar now sold appears to have been prepared by one of the modifications of Martignier's process, in which neutralised wine lees are treated with an excess of a saturated solution of potassium sulphate, the gypsum separated, the solution of potassium tartrate decolorised with animal charcoal, and sufficient sulphuric acid added to convert the neutral into the acid tartrate. As thus prepared, one would expect the cream of tartar, though free from calcium tartrate, to contain potassium and calcium sulphates, and this is found to be the case in many samples of commerce.

In examining cream of tartar, the author bases his conclusions on the following data:—The acidity of the sample may be due to potassium hydrogen tartrate and potassium hydrogen sulphate; the normal salts present may be, calcium tartrate, potassium sulphate, calcium sulphate, and neutral potassium tartrate. On ignition—(1.) The potassium hydrogen tartrate leaves potassium carbonate in amount exactly corresponding with the original tartrate. (2.) Any potassium hydrogen sulphate reacts with the potassium carbonate, forming the neutral sulphate, water, and carbon dioxide. (3.) Calcium tartrate yields calcium carbonate, which reduces the alkalinity of the soluble ash. The neutralising power of the total ash will exceed the acidity of the original cream of tartar. (4.) Neutral potassium sulphate does not affect the result. (5.) Calcium sulphate reacts with the potassium carbonate, forming calcium carbonate and potassium sulphate. The alkalinity of the soluble ash is reduced. (6.) Potassium tartrate produces potassium carbonate, but the ash will require more acid for neutralisation than the ash derived from an equal weight of potassium hydrogen tartrate. No neutral potassium tartrate can be present where the cream of tartar has been prepared by Martignier's process, and the author doubts its occurrence in samples prepared by the old method.

If a sample of cream of tartar be free from uncombined sulphuric and tartaric acids, and contain only calcium and neutral potassium sulphates and potassium hydrogen tartrate, the acidity of the original sample will be exactly equivalent to the alkalinity of the total ash. The presence of potassium hydrogen sulphate will cause the original acidity to be in excess of the total alkalinity of the ash, whilst calcium tartrate will make the acidity less than the alkalinity of the ash. Both of these salts cannot be present in the same sample of genuine cream of tartar. Where calcium sulphate is present, the B.P. test under-estimates the amount of potassium hydrogen tartrate, in the proportion of 2.77 per cent. for every unit of calcium sulphate. The author considers that titration of the original sample with caustic alkali, with a limit for the allowable amount of sulphates, would be preferable.

For further examination the following process is proposed:—

(1.) 1.881 grm. of the sample, free from moisture, is dissolved in hot water and titrated with caustic alkali, phenolphthalein being used as indicator. In the absence of potassium hydrogen sulphate and free tartaric acid, each c.c. of

alkali represents 1 per cent. of potassium hydrogen tartrate.

(2.) Ignite 1.881 grm. for ten minutes, boil with water, filter and wash the residue.

Titrate the filtrate with $\frac{N}{10}$ HCl and methyl orange.

With pure tartar, the quantity of acid used will equal that consumed in the previous titration of the bitartrate with alkali. Every c.c. of deficiency of acid equals 0.36 per cent. of calcium sulphate or 0.72 per cent. of KHSO_4 . Any excess of acid needed points to the presence of normal potassium tartrate, every c.c. representing 0.6 per cent. thereof. If the titrated liquid be treated with barium chloride, the BaSO_4 found will form a measure of the CaSO_4 or K_2SO_4 present.

(b.) The carbonaceous residue is ignited, dissolved in 20 c.c. of decinormal acid, filtered from any insoluble residue, and the filtrate titrated with decinormal acid. Each c.c. corresponds to 0.50 per cent. of calcium tartrate, or 0.36 per cent. of calcium sulphate (anhydrous).—C. A. M.

Quinine Sulphate, The Testing of. Melchior Kubli. Pharm. Zeit. für Russl. 34, Nos. 34—37.

THE author states that none of the tests usually employed for the detection of the other cinchona alkaloids in quinine sulphate are satisfactory, and proposes the two following:—

The Water Test.—The foreign alkaloids are less soluble than quinine, their sulphates more soluble; hence the quantity of water required for the solution of the base liberated from a given quantity of the sulphate affords a measure of the purity of the sample. 1.793 grms. of the sulphate, dried at 40° — 50° C. and thus containing 2 molecules of water of crystallisation, or an equivalent quantity of the crystalline salt, are dissolved by boiling with 60 grms. of water in a tared flask for five minutes. Water is then added from a burette until the total weight is 62 grms. The flask is cooled to 20° C., with frequent agitation, and kept at that temperature half an hour. After filtering through a dry filter, exactly three drops of 10 per cent. sodium carbonate solution are added to 5 c.c. of the filtrate, and water at 20° C. is added from a burette until the opalescence disappears. With pure quinine sulphate, an addition of exactly 10 c.c. of water is required; with a mixture of quinine sulphate with other sulphates, a constant increase above this 10 c.c. is required for every 1 per cent. of the impurity.

The figures are as follows:—

	C.c.
Hydroquinine sulphate	0.6
Quinidine sulphate	2.6
Cinchonine sulphate	0.7
Cinchonidine sulphate containing 3 per cent. of hydroquinine sulphate	0.1
Cinchonidine sulphate containing 2.5 per cent. of quinidine, 2.5 per cent. of cinchonine, and 30 per cent. of hydroquinine sulphates	0.75

The large increase in the case of quinidine sulphate is due to the greater solubility of the double sulphate of quinidine and quinine, so that a larger precipitate is produced on the addition of sodium carbonate than with the other mixtures. The author considers that the maximum rise for each percentage of impurity may be regarded as 1 c.c., and the minimum as 0.7 c.c.; he suggests that a total of 12 c.c. should be taken as an official figure, thus allowing about 3 per cent. of impurity.

The Carbon Dioxide Test.—When sodium carbonate is added to a solution of quinine sulphate, saturated at the ordinary temperature, the precipitated alkaloid is very easily soluble in sodium bicarbonate, and on passing a stream of carbon dioxide through the solution, normal quinine carbonate separates in bunches of needles. Quinine carbonate is only very slightly soluble in water, effervesces with acids, is readily soluble in alcohol, and slightly alkaline to litmus paper. In the presence of cinchonine, cinchonidine, and quinidine, the separation of the crystals is lessened and delayed, and may be altogether prevented; hydroquinine does not exert the same influence.

To 5 c.c. of the saturated solution of quinine sulphate prepared as before, are added three drops of sodium carbonate solution, and the precipitate is dissolved in 5 c.c. of bicarbonate solution free from normal carbonate. Carbon dioxide,

which must be free from air from the beginning, is passed in at the rate of 80—100 bubbles per minute for 30 minutes at 15° C.

The cylinder is then gently shaken until the volume of the supernatant liquid remains constant; with a voluminous precipitate this will occupy about 30 minutes. The contents are then placed in a cylinder graduated to $\frac{1}{10}$ or $\frac{1}{2}$ c.c. and allowed to stand until clear; with samples containing 1—3 per cent. of impurity, the liquid must frequently stand till next day, the separation being hastened by agitation. Pure quinine sulphate gives a precipitate of 1.4—1.5 c.c. of amorphous flocks to the naked eye, but under the microscope seem to be bunches of needles; with 1 per cent. impurity, the precipitate is granular; with 3—4 per cent., it glistens by transmitted light; and with more than 10 per cent. there is no precipitate.

Quinine Sulphate containing	Sulphates of				Remarks.
	Cin- chonidine.	Quinidine.	Hydro- quinine.	Cin- chonine.	
Per Cent.	C.c.	C.c.	C.c.	C.c.	
1	1.8—1.9	1.8	1.2—1.3	1.8—2.1	Partly granular.
5	0.6	Trace	1.2—1.3	1.0	Granular
10	Trace	..	1.2—1.3	Not given	..

Samples with impurities of 1, 2, 3, 4, 5 per cent. would thus require 11, 12, 13, 14, 15 c.c. of water in the water test and give 1.8—2.0 (partly granular), 1.4, 1, 0.8, 0.5 c.c. of precipitate in the carbon dioxide test, the last four precipitates being all granular.

Commercial samples examined by the two tests gave the following results:—

No.	Water Test.	Carbon Dioxide Test.	Impurity.
	C.c.		Per Cent.
1	10.5	1.4—1.5 c.c. not granular	0.5
2	10.5	1.5—1.6 c.c. not granular	0.5
3	15.0	Trace.....	7.0
4	18.5	No precipitate.....	12.0
5	17.0	More than traces.....	7.0 quinidine and cinchonine.
6	16.5	Traces.....	9.0

—A. C. W.

Essential Oils and the like, Detection of the Adulteration of. E. Gossart. Bull. Soc. Chim. 1896, **15**, [3], 597—609, also 666—688.

The principle underlying this method, and its application to the examination of spirits, have been previously noticed (this Journal, 1893, 790). The author now claims the process to be of general utility, and especially serviceable for detecting the adulteration of essential oils with alcohol, turpentine, cheaper essences, &c., and he gives many examples in illustration, for which the original papers must be consulted.

In dealing with any particular essential oil, &c., a test liquid (prepared by adding to a pure specimen of the same oil a certain proportion of the adulterant sought for) is used, drops of which are projected on the surface of the sample under examination. The presence of the particular impurity is then indicated if the drops "roll," and, *vice versa*, its absence (as a rule) if they immediately plunge below the surface. The test fluid is compounded with just sufficient of the impurity to cause 10 consecutive drops of it to plunge in the pure sample. Quantitative indications may then be obtained, if it be noted that the transition stage between rolling and plunging (*i.e.*, when 4—6 drops out of 10 roll, the remainder plunge) corresponds to a more or less definite proportion of impurity in the sample—to be determined by trial. In practice, the sample is then diluted (with a pure specimen) until partial rolling is observed. From the degree of dilution the percentage of impurity may be calculated. Briefly summarised, the method may be summed up thus:—

1. The sample (found to be adulterated) under examination must be diluted with a pure specimen of the same essence, until partial rolling, or cessation of complete rolling, of the test drops is obtained. The corresponding percentage of adulterant multiplied by the degree of dilution represents the proportion of impurity present in the sample.

2. Ten drops are always employed, the number of them that roll being noted.

3. In some cases it is necessary to dilute the test liquid with alcohol, benzene, &c., in order to increase its tendency to "roll"; the sample must then in every instance be similarly diluted prior to examination. This operation must not be confounded with the dilution directed under 1. The latter has for its object the reduction of the particular impurity to a certain recognisable amount, and must be effected prior to the addition of the auxiliary liquid.

—H. T. P.

Trimethylamine, Separation of, from Ammonia. H. Fleck. J. Amer. Chem. Soc. 1896, **18**, 670—672.

The mixed hydrochlorides are repeatedly extracted with boiling absolute alcohol, and the solvent is then distilled off. The residue is then boiled with an excess of caustic soda, the vapours evolved conducted into a large bulk of water, the product exactly neutralised by sulphuric acid and evaporated to dryness. On treating the residue with cold absolute alcohol, trimethylamine sulphate dissolves, whilst ammonium sulphate is insoluble. The alcoholic solution is distilled, and the residue, when dried, gives the amount of trimethylamine sulphate.—A. K. M.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Ozone. C. Engler and W. Wild. Ber. 1896, **29**, 1929.

From the experimental work detailed in this communication, it is concluded that there is now no reaction known by which a modification of oxygen is produced by the decomposition of ozone which can be regarded as the antiozone of Schönbein, Meissner, and others, or as the free ions (—O—) or incompletely combined atoms (—O—O—) of Helmholtz and Richarz.—A. C. W.

Diamonds of Steel. M. Rosset. Comptes rend. 1896, **123**, [2], 113—115.

SIXTEEN Moissan had obtained diamonds by saturating steel with carbon at 3,000°, and cooling under great pressure, it was probable that very hard steel, produced at a high temperature and cooled under pressure, would also contain carbon having the properties of the diamond. After dissolving the metal in strong acids and treating the residue with strong nitric acid, fused potassium chlorate, hydrofluoric and sulphuric acids successively, crystalline residues were obtained having the properties described by Moissan. Regular octahedra of a size not exceeding 15 microns, and irregular fragments as large as 0.5 mm., were found in different samples.—A. C. W.

Ketopentamethylene [Wood-Tar], Condensation with Aldehydes. D. Vorländer and K. Hübner. Ber. 1896, **29**, 1836.

KETOPENTAMETHYLENE (adipinketone), $C_{12}H_{16}O$, can be shown to be present in wood-tar by shaking the fraction boiling at 120°—135° with an equal volume of benzaldehyde dissolved in 6 vols. of alcohol and 1 vol. of caustic soda (10 per cent.). A thick precipitate of dibenzalketopentamethylene, $C_{12}H_{16}O(C_6H_5)_2$, is obtained. Traces of acetone in wood-spirit may be tested for in a similar manner.

Pyroxanthin, obtained from crude wood-spirit by shaking with lime or caustic soda, was shown to be difurfuralketopentamethylene. Adipinketone was also found in acetone oil.—A. C. W.

Antiaris Toxicaria, The Milky Juice of. H. Kiliani. Archiv. der Pharmacie, **234**, 438.

FROM this juice the author has separated antiarol, the trimethyl ether of tetrahydroxybenzene—

which, on oxidation, yields dimethoxyquinone, and the glucoside antiarin, $\text{C}_{27}\text{H}_{40}\text{O}_{10} + 4\text{H}_2\text{O}$ (Muhler, Ann. **28**, 304, gives $\text{C}_{14}\text{H}_{20}\text{O}_5 + 2\text{HO}$), which, on warming with dilute hydrochloric acid, is split up into antiarigenin, $\text{C}_{21}\text{H}_{30}\text{O}_5$, and a sugar, $\text{C}_6\text{H}_{12}\text{O}_5$, isomeric with rhamnose.

—A. C. W.

Mannose, Sorbose, and Galactose; Ammonia Derivatives of. Lobry de Bruyn and F. van Leent. Rec. trav. Chim. des Pays-Bas, 1896, **15**, 81.

THE ammoniacal solution of pure mannose syrup in methyl alcohol, deposits, on the addition of ether, an amorphous mass, gradually becoming crystalline, and having the formula $\text{C}_{12}\text{H}_{23}\text{O}_{10}\text{N}$, its rotatory power being $[\alpha]_D = -28^\circ.3$. This derivative of mannose differs from the corresponding ammonia compounds of the other sugars, in that it is formed by the union of 2 mols. of mannose with 1 mol. of ammonia, the reaction being accompanied by separation of water. The sorbose derivative, which may also be prepared as above, is very unstable; probably sorbosamine agrees with the formula $\text{C}_6\text{H}_{13}\text{NO}_4$. Galactosamine, when boiled with methyl alcohol, loses one-half its ammonia, with the deposition of a very hygroscopic crystalline body, having the formula $\text{C}_{12}\text{H}_{23}\text{O}_{10}\text{N}$. No salts of this substance could be prepared, and it is probable that under the action of acids it is split up into sugar and ammonia.—C. S.

Mushrooms, Action of the Oxidising Ferment of, on Oxidisable Compounds. E. Bourquelot. Comptes rend. 1896, **123**, 315—317.

THE author describes the action of the ferment of mushrooms on several phenols and aromatic amines. In the case of orthoeresol, oxidation sets in at once when the solution is neutral, but more slowly when alkaline; the oxidation of the meta-compound takes place in either a neutral or slightly alkaline solution, whilst with paraeresol, the addition of a trace of sodium carbonate assists the oxidation. Hydroquinone, pyrogallol, and resorcinol are also acted upon by the mushroom ferment. Guaiacol and eugenol are rapidly oxidised, and the action takes place much more readily in a neutral or acid (acetic) medium than in an alkaline solution. In the case of the toluidines, the addition of a little acetic acid favours the oxidation, and this is also the case with xylydine.

The author compares the action of the mushroom ferment to that of the oxidising agents used in the production of colouring matters, and he describes the formation of a product analogous to magenta which he obtained from aniline with the help of the fungus *Russula delica*.—A. K. M.

New Books.

THE INDIGENOUS DRUGS OF INDIA: Short Descriptive Notices of the Principal Medicinal Products met with in British India. By KANNY LALL DEY, Rai Bahadur, C.I.E., F.C.S. Late Professor of Chemistry and Chemical Examiner to Government. Hon. Member, Pharmaceutical Society of Great Britain. Joint President, Section of Pharmacology, Indian Medical Congress, 1894, &c. Assisted by WILLIAM MAIR, Assoc. Pharm. Soc. of Great Britain. Second Edition. Revised and Entirely Re-written.

Thacker, Spink, and Co., Calcutta. W. Thacker and Co., 87, Newgate Street, London, E.C. 1896. Price 16s.

THIS is an 8vo. volume, with frontispiece representing the author, Dr. Dey, and a preface by Dr. George Watt, in which comments on the suitability of the work as a students' manual. The author himself specially commends it as a guide to indigenous medicines for students at Netley and elsewhere, proceeding to the Indian Medical Services, and also to Medical Men and Medical Missionaries going to India. Then follow a Prefatory Memoir, an Introduction, Indian Pharmacology—A Review. Tables of British Indian Equivalents, and then the subject-matter proper, filling 334 pages, Appendices filling 14 pages, a Botanical Classification of Natural Orders of Plants enumerated in the work, filling 7 pages, and a copious alphabetical index covering 31 pages.

The subject-matter itself, "The Indigenous Drugs of India," is alphabetically arranged as regards the substances described, so that principal species can be at once turned up in the body of the work, independently of the index. There are four Appendices:—I. Aconitum Napellus, and Aconite Collection in the Himalaya. II. Ailanthus Exceelsa. III. Fluid Extracts. IV. Foods of India.

A SYSTEMATIC HANDBOOK OF VOLUMETRIC ANALYSIS; OR, THE QUANTITATIVE ESTIMATION OF CHEMICAL SUBSTANCES BY MEASURE, APPLIED TO LIQUIDS, SOLIDS, AND GASES. Adapted to the Requirements of Pure Chemical Research, Pathological Chemistry, Pharmacy, Metallurgy, Manufacturing Chemistry, Photography, &c., and for the Valuation of Substances used in Commerce, Agriculture, and the Arts. By FRANCIS SUTTON, F.I.C., F.C.S. Seventh Edition, Enlarged and Improved. J. and A. Churchill, 7, Great Marlborough Street. 1896. Price 18s. 6d.

THE fifth edition of this work was noticed in this Journal, 1886, 619—620, since which the sixth edition has appeared in 1890, and now this, the seventh edition, is issued. The sections of the work altered by reason of general improvement and additions, with others entirely new, comprise chiefly those concerned with the articles on Calibration of Instruments, the Kjeldahl Process, Boric Acid, Hydrofluoric Acid, Fluorides, Arsenic, Chromium, Copper, Cyanogen and Cyanides, Iron, Lead, Manganese, Mercury, Nickel, Phosphoric Acid, Sugar, Sulphur and its Compounds, Tannin, Zinc, Oils and Fats, and Urine.

The subject-matter of the present edition fills 575 pages, and the illustrations number 112. An alphabetical index ends the work, and fills 10½ pages.

The growth and development of the work will be observed by a glance at the notice of the fifth edition, which shows (*loc. cit.*) that this fifth edition contained 483 pages of matter, 8 pages of index, and 90 woodcuts.

Trade Report.

EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

ANTICIPATED RESULTS OF THE SICILIAN SULPHUR TRUST.

U.S. Consular Reports, August 1896, 773.

Consul Canby, of Messina, under date of June 20th, transmitting to the Department a translation of the chief clauses of the proposed sulphur trust of Sicily—fully covered by the report of Consul Brühl, of Catania, printed in Consular Reports, No. 190 (July 1896)—states that it means an enormous advance in price, and will materially affect American interests, the exports to the United States averaging about 100,000 tons annually. The first result will be to direct attention, much more than at present, to the pyrites mines of Spain, although, if reports be true, the same syndicate have made overtures to Sir Charles Tennant, president of the Tharses mines, the largest mines in that country.

The formation of this trust may give additional impetus to the advance of American mines—those of Louisiana, for

instance, where the process has, so it is reported here, long since passed the experimental stage. The existence of this trust will, it is predicted, in a short time place the price of Sicilian sulphur at the highest figure it has ever touched, and if there ever was a time for profitable trade in the American product, as opposed to the foreign product, that time is the present.

Under date of June 17th, 1896, Consul Seymour, of Palermo, transmits the following statistics covering the exports of Sicilian sulphur to the United States:—

Period.	1896.	1895.
	Tons.	Tons.
Month of April	11,970	5,179
Three months ended April 30th	56,305	24,119
Ten months ended April 30th	129,562	82,403
Stock on hand April 30th	137,381	112,000

SOAP IN EGYPT.

Chamber of Commerce Journal, August 1896, 147.

Under the denomination of "common soap," a soap of very ordinary quality is imported into Egypt for laundry purposes and use by the natives. The quantity fluctuates considerably, as is shown by the appended figures for the last ten years, giving the amount of common soap imported (in kilos.):—

1886	5,247,606	1891	4,438,183
1887	1,843,757	1892	6,130,941
1888	3,110,133	1893	5,091,049
1889	3,386,761	1894	4,851,589
1890	4,131,525	1895	5,369,469

Values have latterly fallen, in consequence of increased competition between native-made and imported soap. For the last two years the imports have been derived as follows:—

From	Kilo.	Francs.	Kilo.	Francs.
Turkey	4,544,725	2,306,300	5,268,880	1,992,100
France	133,137	59,300	129,790	55,400
Greece	81,680	40,900	105,210	48,500
England	74,647	37,300	72,273	37,600
Italy	7,170	3,000	10,434	3,700
Austria	4,523	2,300	17,88	800
Belgium	2,431	1,000	5,951	2,300
Other countries.....	3,226	1,500	1,249	500

An investigation made into the characteristics of the various classes of soap in vogue shows that the Syrian product is most esteemed by native consumers, because it is generally dry and hard, containing tallow in proportions varying as the manufacturer has sought to lower his selling price at the expense of quality. According to quality Syrian soap varies from 40 to 80 frs. per 100 kilos, delivered on quay at Alexandria; a current type of Cretan soap fetches 59 frs. 60 per 100 kilos, delivered to warehouse in Alexandria. Grecian soap is not expected to improve its position, owing to the large quantity of tallow contained in it. In Egypt itself the soap-manufacturing industry is a developing one, there now being four factories established and others in course of installation. These factories import their caustic soda and silicate of soda from England and Belgium, their tallow from Italy, and their oils from England, Turkey, and Greece; but cotton oil, extracted in Egypt, is principally utilised. For native-made soaps, those most used fetched, delivered in warehouse: 1st quality, 72 frs. 60; 2nd quality, 62 frs. 20; 3rd quality, 52 frs.; 4th quality, 21 frs. 50 per 100 kilos.; while black soap is quoted at 50 frs., all per 100 kilos. A somewhat large quantity of soft soap is used in the country for the lubrication of driving-belts and various cleaning and machinery purposes. England supplies the main part, as her soft soap is of a more pleasing colour than the black-looking Marseilles product, but even the military authorities have recognised that the French product has some virtues

by latterly giving it preference. Perfumed soaps find only a limited outlet, the total value only reaching 122,200 frs. in 1895, but that was well in advance of 1894, with only 87,300 frs. as the value. The chief amounts were credited as follows:—France, 31,309 frs.; England, 30,300 frs.; Germany, 22,200 frs.; Italy, 21,800 frs.; next coming Belgium, Austria, Hungary, and Turkey.

ZINC IN RUSSIA.

Chamber of Commerce Journal, August 1896, 148.

After coal, zinc production occupies the chief place in the rising industry of Poland, and its development is the more rapid because the only mines known in the Empire are situated in the basin of Sosnowice-Dombrowa. Two companies possess the monopoly: that of Sosnowice, which acquired in 1890 the mines and works of Kramst; and that of Derwiz-Szewcow-Pomeranoff, to which, in 1891, the Government farmed for sixty years its works in the basin of Dombrowka. The zinc ore workings are exclusively concentrated in the neighbourhood of the town of Olkusz. The ore there found in the largest quantity is calamine, which gives, after smelting, 7 to 30 per cent. of zinc. There is also found, but in a lesser degree, "blende" or native sulphurous zinc. As the upper deposits are becoming exhausted, the two companies have undertaken the construction of galleries intended to divert the water and to allow of a search at a greater depth for thicker beds of ore. When extracted the ore is transported, either by waggon, or by the Lvangrod-Dombrowa railway, about 25 kiloms. away from the mines to the factories of Bendrin and Pauline. There are only two rolling mills in the kingdom—one at Sosnowice and the other at Slawkow—whose output is in the shape of plates or sheets; whilst there is also a zinc-white factory. On comparison of the results of 1895 with those of the preceding year, an important increase in production is to be noted. During last year 125,634 poods more of calamine were extracted, and 31,339 poods more of zinc were produced than in 1894; while the rolling mills turned out more by 25,892 poods, and the output of zinc-white was higher by 1,100 poods. The figures on which those improvements were registered are given below in poods:—

Product.	1894.	1895.
Calamine extracted	3,367,237	3,492,871
Zinc made	274,774	306,113
Output of the rolling mills	146,337	172,229
Output of zinc-white	41,002	42,102

These works employ 2,100 hands, of whom 1,400 are in the mines and 700 in the factories. Owing to the fall in prices the prospects of the industry are not very favourable, but it is thought that they will improve, as the heavy import duties render competition almost impossible on the part of the Silesian industry.

CHLOROFORM, ETHERS, &c.

Report of Commissioners of Inland Revenue for Year ending March 31st, 1896.

Chloroform has the distinction of having yielded the smallest amount of revenue to the Customs of any article on the tariff. It is subject to a duty of 3s. 1d. per lb., and the gross receipt of duty acknowledged by the Department for the year 1895-96 is 1*l.* sterling. In the previous year it was 6*l.* A single Winchester seems to have been imported. Chloral hydrate pays 1s. 3d. per lb.; the imports of the past year paid duty 1,131*l.*, or 8*l.* less than in the previous year. Collodion realised 12*l.* in each year (at the rate of 25s. per gallon). Acetic ether is charged at 1s. 10d. per lb., butyric ether at 15s. 8d. per gallon, sulphuric ether at 26s. 2d. per gallon, and iodide of ethyl at 13s. 7d. per gallon. These preparations yielded 160*l.*, 277*l.*, 15*l.*, and nothing respectively in 1895-96; in the previous year the amounts were 35*l.*, 154*l.*, 28*l.*, and nothing in the same order, showing a notable increase in the imports of acetic and butyric ether. Transparent soap, in the manufacture of which spirit has

been used, pays a duty of 3*d.* per lb. British manufacturers seem able to more than hold their own in this. The duty paid in 1895-96 was 118*l.*, while it was 140*l.* in the previous year.

METHYLATED SPIRIT.

Report of Commissioners of Inland Revenue for Year ending March 31st, 1896.

There are 23 licensed makers of methylated spirit in England and Wales, two in Scotland, and one in Ireland. The retailers number 10,871 in England and Wales, 1,246 in Scotland, and 543 in Ireland. There are two more English makers' licences granted than in 1894-95, while retailers have increased by 442 in England, by 75 in Scotland, and by 39 in Ireland. That the use of methylated spirit is increasing is evident from the statement that 3,930,072 galls. were received for methylation last year, and 3,587,003 in the year before.

GENERAL TRADE NOTES.

THE EXPORT OF ILLUMINATING OIL FROM BATOUM.

According to the *Melbourne Journal of Commerce*, in 1895 Russia shipped 292,424,000 galls. of illuminating oil to the following countries:—

Austria-Hungary.....	29,555,000
Belgium.....	10,827,000
Bulgaria and Servia.....	3,839,000
China.....	12,562,000
Egypt.....	8,472,000
United Kingdom.....	30,865,000
France.....	15,896,000
Germany.....	4,835,000
Holland.....	1,601,000
Italy.....	6,147,000
India.....	45,822,000
Japan.....	3,800,000
Java.....	15,056,000
Turkey.....	19,671,000
Far East.....	43,107,000

The balance went in smaller lots to other countries, 28,000,000 galls. going to Russian ports reached *via* Batoum. The shipment of nearly 300,000,000 galls. of refined oil from the port of Batoum in 1895 is of no slight importance when it is borne in mind that the United States exported in 1895 only 677,000,000 galls., or but little more than twice as much.

THE MATERIALS FOR DENATURING SPIRIT.

Chem. Zeit. 1896, 533.

A mixture of wood spirit and pyridine is used in Germany for denaturing spirit; the former is entirely supplied by the home manufacturers, whilst about one-half of the latter has to be imported from England. There is also a considerable difference in the price: one litre of wood spirit only costs 0.55 mark, against 1.40 mark, the price of pyridine.

This mixture has been in use for the last nine years, and, taking into consideration the above facts, it appears, in the writer's opinion, to be desirable, in the interests of German manufacturers, to revise the regulations.—A. L. S.

THE TRADE AND INDUSTRIES OF BERLIN IN 1895.

Berichte über Handel u. Industrie von Berlin i. J. 1895.

POTATO PRODUCTS (pp. 108--109).—Business remained quiet throughout the year, the textile and paper industries not being sufficiently developed to exert a favourable influence. Speculation being prevalent only to a limited extent, the few buyers of starch and flour for a rise were caught in consequence of the heavy crop and large stock left over from the previous year. The price per 100 kilos. of potato starch and flour decreased regularly from 17.10 marks in January down to 14.20 in November and December. The chief consumers were the dextrin manufacturers, the output in this article being 87,250 sacks, against 73,596 sacks in 1894, but the export trade in starch decreased by some 65,800 sacks.

The wet starch trade suffered in consequence of American (maize) competition with the exports of potato sugar and syrup, prices falling from 9.40 marks (January) to 7.65 (December). The home trade in syrup about maintained its position, but the profits were small, prices declining from 20 marks per 100 kilos. in January to 17 marks in November—December.

SPIRITS (pp. 114--115).—The production of spirits did not fall below 1894 figures to any appreciable extent, but the large stocks carried over from the former year, coupled with the slow demand, made the outlook rather depressing. However, the introduction of the export bounty of 6 marks per hectolitre caused a revival of the foreign trade, the exports between August and December amounting to 108,763 hectolitres, an excess of 83,343 hectolitres over the corresponding period of the preceding year. The bad credit of some of the purchasing countries and the keen competition of the cheap maize spirits militate against the export trade in Berlin-made fine spirits. The French market for these is closed by reason of the high tariff and the improved quality of the French home-manufactured article, and the first-named cause also operates in respect of Spain. The Silesian distillers secure the Italian trade and Bohemian molasses spirit supplies the decreasing demands of Switzerland, at least in the cheaper grades. Most of the bountied spirit goes to the Levant, and this trade is in the hands of distillers on the Baltic coast, they having the advantage over Berlin in freights. Portugal is about the only buyer of Berlin wine spirit, and that not in large quantity.

In the home trade Berlin suffered, before the modification in the spirit tax, from the competition of the molasses distillers, but since the latter have found an outlet abroad, the home market has not been so much cut up.

The price of spirits was rather higher than 1894, 70 per cent. spirit being quoted at 32.5, against 32.1 in December. The bounties for rectifying spirit are still too low, even for the finest qualities, to offer any adequate rate of interest on the large capital required.

CEMENT.—The industry laboured under even more unfavourable conditions than before, prices having receded, and the carriage of coal increased in consequence of the scarcity of water. In the last half of the year the article was in more demand for the erection of the exhibition buildings. Manufacturers have established a minimum price for the ensuing twelve months, which should lead to an improvement in the condition of the industry.

DRUGS (pp. 176--178).—The trade is in a more satisfactory condition than it has been for many years, the use of medicaments in Germany having largely increased since the introduction of the sick club and accident insurance legislation for the working classes. An increasing tendency to revert to vegetable medicaments is noticed. Export business was very good, Central and Southern America (especially Argentina) and Russia being the largest buyers. The establishment of German banks on the other side has greatly facilitated business and lessened risks. The tariff war with Spain affects the drug trade, and the treaty with Russia has not increased the volume of business beyond that formerly done, many buyers having become accustomed to place their orders with other countries. Prices, after sinking for a long time, are firmer, and less affected by speculation.

Ethereal Oils.—The chief oils rose considerably in price, especially the Messina essences, bergamot, citron, and orange. Peppermint, rose, and neroli oil were also dearer, but aniseed, fennel, angelica, and coriander oil receded in price.

Petroleum spirit rose some 30 per cent. in the spring, in sympathy with petroleum, but rapidly went back in price.

Carbolic acid advanced some 10 per cent. at the close of the year.

Quinine is firm at about 40 marks per kilo.

Cocaine.—The consumption has increased. The maximum of value was reached in March (740 marks per kilo.), but the closing price fell to 500 marks. The new plantations in Ceylon and Java are expected to compete keenly with Bolivia and Peru.

Borax and boric acid, which are controlled by a ring, remained unchanged, and outside makers have ceased to make offers.

Glycerin increased rapidly in value from 75 to 125 marks in consequence of the increased demand for making dynamite and for other purposes, and the diminished production owing to the decline in the stearin candle industry.

Iodine.—The price was kept up by the ring, in spite of outside makers, but the position is precarious, and a drop of 50 per cent. may happen any day. Japan has lately entered the lists as a producer of iodine.

Lactose fell to 85 marks per 100 kilos., but on an agreement of most of the makers, rose to 180 marks.

Salicylic acid and its preparations, manufactured by a large number of new makers, fell 50 per cent.

Tartaric acid recovered from the low price of the preceding year, and reached 250 marks per 100 kilos.

Bismuth and its salts underwent great fluctuation, falling from 17 marks per kilo. in 1894 to 7.50 marks in 1895.

DYESTUFFS.—*Indigo*.—The conditions have greatly improved, the Bengal crop, 160,400 maunds, being almost double that of 1894. In Lower Bengal and Behar the quality was generally good, and in Benares, average. But the Oude indigo was chiefly low grade. Prices increased in December 1894, so that in the following month fine Bengal touched average rates, Behar being 15 rupees lower, and Oude standing at 50 rupees over opening prices. There being little stock, good business was done, and importers who had bought early made good profits. The Madras crop was also large (204,880 Madras maunds) and of satisfactory quality. In Java, 590,000 kilos. were produced, but prices were comparatively high and business consequently restricted. Guatemala shipped 6,861 "serone" to Europe. The prospects of the new crop being unfavourable, prices for all grades have an upward tendency.

Cochineal.—A short crop readily disposed of at high prices.

Dyewoods.—The position of the market was satisfactory, the vacillating tendency of the early season being followed by a firmer tone, especially towards the end of the year.

Logwood.—The unsatisfactory quality of many of the Laguna shipments diverted the attention of buyers to other kinds, Yucatan and Campeachy finding ready purchasers. Cape Haiti logwood was poor, and lost its market status. Jamaica wood met with extensive application throughout the year. Yellowwood remained low, only the inferior qualities, being scarce, advancing.

The values of red-wood depreciated, the supply being large. Altata Lima wood was good in quality.

Quebracho Wood.—Large quantities were shipped to Europe, and prices receded in the autumn, but recovered towards the close of the year.

Myrabolams.—The demand was extensive, but the abundance of low-grade stuff kept down the price of the better qualities coming into the market in the late summer and autumn.

BONES, BONEMEAL, AND OTHER MANURES (p. 181).—The bone trade suffered through the diminished demand for bonemeal, and although the Association of Bone Grinders became an accomplished fact, the weakening of Indian prices kept values down.

The demand for artificial manures was restricted in consequence of the unsatisfactory condition of agriculture, and the agitation against the use of these fertilisers.

Bonemeal suffered most, the existence of the trade being imperilled by the publication of Maerker's adverse deductions from his experiments on the manurial value of ground bones, notwithstanding that these views are not shared by other chemists of repute.

Superphosphate also declined to unprofitable prices as a result of over-production—the increased quantity of sulphuric acid at disposal, since the introduction of new methods of soda manufacture, being devoted to this purpose. Florida phosphate exhibited a parallel tendency, and any improvement depends on the agricultural situation.

The increased stocks and diminished rates of nitrate of soda forced down the price of sulphate of ammonia. Attempts to syndicate the nitrate exporters have so far been without result. Other nitrogenous substances, such

as blood meal, horn meal, flesh meal, and leather meal, were neglected, as a result of cheap ammonia salts and the warnings against animal nitrogen issued by the agricultural experimental stations.

Glue alone met with a good sale, the increased demand and cessation of manufacture during the hot summer months clearing out stocks and raising values by 5 marks per 100 kilos. America and England bought freely.

Extracted bone fat kept at the same level as in the previous year, an advance in the autumn being counteracted by the lowering of the rates for tallow.

OILS AND FATS (pp. 181–183).—*Linseed oil* is mostly obtained from the Harburg, Breslau, and Danzig crushers, also from England and Holland. Imports (including cottonseed oil to 1.7), 2,264,199 kilos. Prices 48 to 50 marks per 100 kilos. for good clear oil.

Cottonseed Oil.—Large quantities imported from England at 43–45 marks per 100 kilos. for double refined Hull oil.

Hemp Oil.—Seldom offered.

Olive oil came chiefly from the Levant, Spanish and Italian prices being too high on account of the short crop. Imports, 320,300 kilos.; denaturised oil, 397,339 kilos. Prices: prime Smyrna, 64–69 marks; Italian green sulphur oil, 45–48 marks.

Palm oil sold easily at 48–50 marks for prime Lagos.

Cocoanut Oil.—Values receded until autumn, but improved as Indian prices advanced. Most of the oil is prepared from Coprah at Harburg and Magdeburg. Prices: 50–53 marks; imported Cochin oil, 60–63 marks.

Palm kernel oil comes on the Berlin market from the Harburg and Magdeburg crushers, and one works in Berlin. Best pressed oil made 45–47 marks.

Tallow.—The plentiful supply at low rates from Australia depressed values. Imports (including other animal fats), 2,688,875 kilos. German candle tallow made 58–55 marks, soap grades 53–48; Australian, 48–56, according to quality, closing firm; Russian (soap), 90–88 marks.

Olein.—The market is supplied from Belgium, Holland, Hamburg, and the Berlin factories, and Newsky olein from St. Petersburg again appeared after a long interval. Trade in the summer was brisk, to meet the demands of the textile industry, but slackened off later. Prices: saponified olein, 51–50 marks; distilled 45–50 marks, rising to 47–51; Newsky, 51 marks.

Fish Oil.—The meagre results of the Norwegian cod fishery caused an advance in values. Pale Greenland seal oil made 46–48 marks; Copenhagen seal, 58; Bergen brown liver oil, 42–50 marks.

Fats.—The inland and American makers sent regular supplies at weakening rates. Prices: natural bone fat, 44–42 marks; extracted, 40–38 marks; medium lard fat, 43–41; fulling grease, 30–36, according to quality.

Mineral Oils.—Large quantities were sent from Russia and America. Prices: low grades 20–28 marks; medium engine and cylinder oils, 30–45; heavy cylinder oils, 50–80 marks.

SOAP, PERFUMES, AND CANDLES (pp. 182–183).—*Household Soaps*.—The cheapness of fat enabled makers to secure a satisfactory margin during the first six or eight months, but selling prices weakened subsequently. The volume of trade was normal, and the results showed a marked improvement over the two preceding years. But little export trade is done, buyers' ideas of price being too low.

Toilet Soaps and Perfumery.—An increased consumption of toilet soaps is recorded, but prices ruled too low in comparison with raw materials. Quality has improved in consequence of home and foreign competition.

The abolition of the permission to employ duty-free spirit for perfumery has had an unfavourable effect on the industry, which the increased import duties and the return of duty on the alcohol in exported wares have not counteracted. French manufacturers have established works in Germany to compete with the native makers. The export trade is small, owing to the preference accorded to French and English goods; and a similar preference is manifested by some dealers in Berlin for French extracts.

Some 1,350,000 kilos. of cocoanut oil and 500,000 kilos. of tallow were consumed in the manufacture of toilet soaps.

Stearin and Candles.—The position of the stearin industry improved, and, prices of fats being low and steady, the rates for candles were uniform at 100, 90, 80 marks for the three grades manufactured. Business was very quiet until the end of August, when the Sedan celebration caused a large increase of orders, and the trade then continued good till the end of the year.

Glycerin fluctuated greatly, and prices in the Paris market, influenced by the American demand, rose from 62.50 francs to 75 francs (July), and, by leaps and bounds, to 125 francs in December, closing 5 francs lower at the end of the month. The short supply is due to the decreased production of stearin candles of late years, and to the prices having been too low to make the recovery of glycerin from spent soap lyes profitable.

THE CHEMICAL INDUSTRIES OF BERLIN (pp. 183—186).—So far as quantity of produce is concerned, the year proved a very favourable one, but in many instances prices were unsatisfactory. The various commercial treaties seem to have helped only a few articles, and the tariff war with Spain has almost killed the trade with that country. Complaints are rife that the high railway rates spoil the German manufacturers' chance of competing with foreigners.

Nitrogenous raw materials steadily decreased in value throughout the year. *Nitric acid*, apparently independent of the price of nitrate of soda, averaged 23 marks per 100 kilos., packed for 36° refined acid, but *sulphate of ammonia* fell every month.

Carbonate of ammonia was in good demand at 69—70 marks *ex works*. *White crystallised sal ammoniac* found increasing use for battery purposes at an average of 59 marks per 100 kilos., but was affected by the fall in *ammonia*, which declined from 36 marks, packed, to about 30 marks (sp. gr. 0.910). 96 to 98 per cent. *potash*, notwithstanding the competition of substitutes, maintained its value, 36 marks, and even rose a couple of marks at the end of the year, stocks being short.

The international associations controlling the production of *oxalic acid* and its salts kept the price steady at 70 marks. *Boric acid* and *borax* were in brisk demand, at about 60 and 40 marks respectively.

Chlorate of potash continued depressed, prices falling to the extremely low rate of 80 marks per 100 kilos. for technically pure chlorate.

Calcined Glauber Salt.—To protect themselves from further loss, the associated makers raised the price a little, but, notwithstanding the fair amount of inquiry, little profit was made.

Crystal soda sold in increased quantity, but to small advantage, no advance being obtainable, the opening of another factory increasing the already keen competition.

Water glass remained on the same level as 1894, both in price and in volume of business; the exports showed a slight falling off.

A large business was done in *concentrated sulphuric acid*, but even the previous low prices could not be maintained, the inferior grades for agricultural purposes selling extremely cheap. *Hydrochloric acid* fell from 6 marks to 5.50, in consequence of over-production.

Wood spirit declined in the first half of 1895 to the lowest prices ever known, but recovered a little subsequently, and the same remarks apply to *methyl alcohol*. *Acetic acid* also receded in value in sympathy with calcium acetate, but America reports an improved tone, which should react on this market.

A further increase in the consumption of *liquid carbonic acid* for mineral waters and raising beer is noted. The apparent large margin between cost and sale price caused a number of new enterprises to spring up, so that values declined, even in the summer season, although the demand was larger. Prices at the end of the year ruled from 32½ to 30 pfennige per kilo. wholesale. The export business is small, adverse tariffs and high transport charges crippling the Berlin trade in this direction.

The position of the *coal-tar products* trade gradually but decidedly improved. Pitch was in good demand, and the

higher prices obtainable reacted on the crude coal-tar market. Good business, though at low rates, was done in oils for impregnating and coating purposes (carbolineum, &c.).

In the finer products, *anthracene* only maintained the rates of the previous year, but *benzol* and *naphthalin* sold well, the former being in increased demand for carburetting and anilin colour making, so that a scarcity set in at the end of the year and prices almost doubled. The advance is not expected to be of long duration, an extension of the manufacture by the coke factories being in contemplation.

Naphthalin is on a better footing, the whole production finding a ready market for colour-making and disinfecting purposes.

Pyridine was also in good demand, and prices rose some 30 per cent., chiefly through the combined action of the English tar distillers, a cause which operated also in the case of *anthracene*. The large stock of this latter article in the hands of the syndicate has been apparently almost exhausted by the increased export.

An increased consumption of the *intermediate products for the coal-tar colour industry* is also apparent. Foreign competition in these articles is keen, the producers being able, by making use of inland water carriage, to undersell the German makers even in Germany. The only remedy would appear to consist in the imposition of a special tariff.

Activity prevailed in the *coal-tar colour industry*. Prices, which were previously regular, rose suddenly in the final quarter, even more rapidly than the rates for *benzol*. The large shipments of aniline oil to America depleted stocks to an extent almost unknown hitherto. The activity of the colour-consuming industries, coupled with the steadiness of exchange and other causes, contributed to the development of the trade, England and America being the principal foreign buyers. Sales to Russia and Austria might have been larger had the article received more attention in the framing of the commercial treaties, and, as for the Spanish trade, unless some agreement is arrived at, this market will be lost to Germany.

In the *cheaper, innocuous, chemical pigments*, the only increase of business noted is to America and Belgium, the inland trade and the exports to the treaty countries exhibiting no development.

Lacs and varnishes evinced considerable improvement, industrial requirements compensating for the reduced demand from the building trade. A satisfactory business was done with Belgium and Sweden, but high rates of transport place Berlin at a disadvantage except where water carriage is available.

The values of many *pharmaceutical chemicals* declined, especially *salicylic acid*, which fell 4 marks per kilo. in January, through an extension of the number of works. In gall products, glycerol, and a few other articles, the market conditions were, however, more favourable. The very large and unexpected additions to the Italian tariff on chemicals greatly hindered the export trade to that country.

AMERICAN PETROLEUM IN 1895.

Ironmonger, September 19th, 1896, 481.

The complete statistics relating to the production and distribution of American petroleum for the year 1895 have just been prepared by Mr. Joseph D. Weeks, and issued by the United States Government. The figures are of exceptional interest, seeing that they show, contrary to general expectation and in opposition to the course of prices, a considerable increase in the production last year. "The most notable features in connection with the production of crude petroleum in 1895," says Mr. Weeks, "are (1) the notable increase in production, especially in Ohio, Indiana, and California; (2) the decrease in stocks; (3) the rise in prices; and (4) the extension southward of the profitable producing districts in the Appalachian range."

The production of petroleum in the United States increased from 49,344,516 barrels in 1894 to 52,983,526 barrels in 1895, most of the important producing districts sharing in this increase. The production of Pennsylvania increased from 18,077,559 barrels in 1894 to 18,231,412 barrels in 1895—an increase of 153,853 barrels, or eighty-five

hundredths of 1 per cent.; of Ohio from 16,792,154 barrels in 1894 to 19,545,233 barrels in 1895—an increase of 2,753,079 barrels, or 16·4 per cent. This increase in Ohio was fairly distributed throughout the two important Ohio producing districts. The production of Indiana increased from 3,688,666 barrels in 1894 to 4,386,132 barrels in 1895—an increase of 697,466 barrels, or nearly 19 per cent.; while the production of California, owing to the new discoveries at Los Angeles, increased from 705,969 barrels in 1894 to 1,208,482 barrels in 1895—an increase of 71 per cent., the largest percentage increase of any of the States. On the other hand, there was a slight decrease in the production of West Virginia and New York. The “barrels,” it may be mentioned, are the American ones of 42 Winchester gallons, which is almost equivalent to 35 Imperial gallons. The stocks of crude petroleum in the Appalachian oil field at the close of 1895 were 5,344,784 barrels, as compared with 6,499,880 barrels at the close of 1894. The largest stocks at the close of any one month in 1895 were 5,859,348 barrels in January, as compared with 11,755,219 barrels, the largest stocks in 1894, which were also at the close of January. The smallest stocks at the close of any one month in 1895 were those of June, being 4,275,506 barrels, while the smallest stocks at the close of any one month in 1894 were those of December, as noted above. The average stocks at the close of each month in 1895 were 4,879,775 barrels. The average price of oil certificates in Pennsylvania in 1895 was 1·35½ dols., as compared with 83¢ c. in 1894, and was the highest price since 1877. The total value of the petroleum produced last year was 57,691,279 dols., or about 1·09 dols. (say, 4s. 6d.) per barrel. The increased production of California has arisen chiefly in the Los Angeles district, large deposits having been discovered almost in the centre of that beautiful city. Of the 2,225,308,092 gallons of crude petroleum produced last year the exports were:—Crude, 111,285,264; naphthas, benzine, gasoline, &c., 14,801,224; illuminating, 714,859,144; lubricating, 43,418,942; and residuums, 137,508 gallons. To the United Kingdom the exports were as follows:—Crude, 3,997,013; naphthas, 7,343,355; illuminating, 279,064,124; and lubricating, 21,209,497. For illuminating oils the United Kingdom is by far the largest customer. Germany coming second, *longo intervallo*, with a total of 100,829,113 gallons. Of crude oil, France is far and away the best customer.

BOARD OF TRADE RETURNS.

SUMMARY OF IMPORTS.

Articles.	Month ending 31st August	
	1895.	1896.
	£	£
Metals.....	1,579,276	1,891,201
Chemicals and dyestuffs	514,841	403,728
Oils.....	679,032	642,811
Raw materials for non-textile industries.....	5,056,281	5,036,984
Total value of all imports	34,587,396	32,472,622

Monthly Patent List.

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

18,259. H. A. Jones. Improvements in deoxidising furnaces. Aug. 18.

18,287. W. M. Fowler. Improvements in clarifying liquids. Complete Specification. Aug. 18.

18,377. C. W. Ramstedt. Improvements in apparatus for heating or cooling liquids. Aug. 19.

18,383. J. F. Stephenson. An improved apparatus for automatically removing solid matter from water or other liquids. Complete Specification. Aug. 19.

18,455. W. C. Welsh. Improvements in smoke-consuming furnaces. Aug. 20.

18,706. E. M. V. Gibb. Improvements in thermometers. Aug. 24.

18,717. A. J. Boulton.—From C. A. Macdonald. An improved mode of and apparatus for cooling, purifying, and drying air for chilling and freezing purposes. Complete Specification. Aug. 24.

19,039. W. Defries. Filtering apparatus. Aug. 28.

19,172. T. F. Irwin, J. J. Atkinson, and J. D. Young. Improvements in apparatus for filtering liquids. Aug. 31.

19,290. A. J. Boulton.—From O. Patin. Improvements in or relating to electrical furnaces. Sept. 1.

19,297. W. R. Lake.—From R. Spasciani. Improvements in carboys, demijohns, and the like. Sept. 1.

19,042. G. Obitz. Improved method of and means for supplying fuel to furnaces and the like. Sept. 2.

19,405. E. Dieble. An improved continuous counter-current saturation apparatus. Complete Specification. Sept. 2.

19,483. W. O. Thomas. Improvements in compressors and pumps. Sept. 3.

19,764. W. R. Lake.—From A. Schwabe. An improved method of and apparatus for maintaining a uniform temperature in laboratory ovens, incubators, drying rooms, and the like. Complete Specification. Sept. 7.

19,800. T. Preece and A. Preece. Improvements in combined self-producing gas furnaces and muffles for use in enamelling metallic articles. Sept. 8.

20,004. H. Ward and F. W. Nock. A cock for combining water and steam in any desired quantities. Sept. 10.

20,987. J. von Grubinski. Apparatus for purifying and heating feed water for steam generators. Complete Specification. Sept. 10.

20,209. W. C. Thomas. An improved apparatus for charging gas producers. Sept. 12.

COMPLETE SPECIFICATIONS ACCEPTED.*

1895.

15,958. L. M. H. R. Baudoin and P. E. L. Schribaux. Process and apparatus for concentrating liquids. Aug. 26.

16,058. H. C. Michell. Manufacture of flake mica for boiler coverings and other uses. Sept. 2.

16,137. J. G. Culvert. New or improved means and apparatus for bringing into intimate contact with each other liquids of different densities. Aug. 26.

17,912. F. Garros. Filtering apparatus. Sept. 16.

18,722. A. W. Paul. Condensers and like apparatus for use in the transference of heat between fluids. Sept. 9.

1896.

8273. J. G. Nash and J. M. Borrow. Process and apparatus for preventing the incrustation in boilers. Sept. 2.

12,015. H. Seek. Apparatus for separating light from heavy substances. Aug. 26.

14,774. O. Guttman. Apparatus for mixing or obtaining reactions between liquids and gases. Aug. 26.

15,682. B. T. Lacy. Roasting furnaces. Aug. 26.

15,757. P. M. Justice.—From H. F. Atkinson. Apparatus for injecting vapour or gas into furnaces. Aug. 26.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

16,277A. L. V. Pratis and P. Marengo. The utilisation of hydrogen gas for the obtaining of light, heat, and power. Date claimed July 22, 1896. Sept. 2.

18,207. R. P. Pietet. Improvements in the manufacture of acetylene, and in apparatus therefor. Filed Aug. 17. Date applied for Jan. 25, 1896, being date of application in France. Complete Specification.

18,208. R. P. Pietet. Improvements in the purification of acetylene, and in apparatus therefor. Complete Specification. Filed Aug. 17. Date applied for Jan. 25, 1896, being date of application in France.

18,493. S. Levin. Improvements in the manufacture of mantles for incandescent gas lighting. Aug. 20.

18,575. J. T. Sheard and the Sheffield United Gas Light Co. Obtaining cyanides in the manufacture of gas. Aug. 22.

18,782. F. J. Koopmann. A process of desulphurising gas in the manufacture thereof. Aug. 25.

18,819. W. Clark.—From A. Meyenberg, M. Wendorf, and S. Heulein. Improvements in incandescent lamps for the combustion of petroleum. Aug. 25.

18,863. T. Holliday. Improvements in apparatus for making and storing acetylene. Aug. 26.

18,888. E. Viard and E. Geisenberger. Improvements in apparatus for generating, storing, and delivering acetylene gas. Aug. 26.

18,915. B. Kosmann. A process for the separation of certain rare earths, and the manufacture therefrom of fabrics for use in incandescent gas lighting. Aug. 26.

18,924. A. Spranger. Improvements in the production or manufacture of ozone solutions. Complete Specification. Aug. 27.

18,992. E. Chesnay and L. Pillion. Improvements in apparatus for generating, storing, and delivering acetylene gas. Filed Aug. 27. Date applied for Jan. 31, 1896, being date of application in France.

19,044. A. F. de Villepigue, V. Fournier, and G. Shenton. Process and apparatus for extracting oxygen from the air. Complete Specification. Aug. 28.

19,059. W. P. Thompson.—From D. H. Chivert, France. Improvements in or appertaining to the production of acetylene gas, and apparatus therefor. Aug. 28.

19,077. H. Maxim. Improvements in the manufacture of incandescence mantles for gas and vapour lamps. Aug. 28.

19,126. G. Voigt. Improvements in apparatus for producing acetylene gas. Aug. 29.

19,215. P. Stiens. Improvements in incandescent mantles. Aug. 31.

19,288. A. J. Boudt.—From H. E. Fuller. An improved construction of apparatus for generating gas by the chemical action of a liquid upon a solid material. Complete Specification. Sept. 1.

19,487. F. H. Bonnefin and D. Hancock. Improvements in or connected with mantles, caps, or hoods for incandescent gas-lighting. Sept. 3.

19,521. J. S. V. Bickford. Improvements in apparatus for lighting and heating by means of petroleum vapour. Complete Specification. Sept. 3.

19,522. V. H. F. de Sonis. Improvement in acetylene gas lamps. Sept. 3.

19,536. G. Beck. New process of fabrication of a mantle or cap serving for gas or other burners to illuminate by incandescence. Sept. 4.

19,639. A. Lege. An improved mode of electrical gas-lighting. Sept. 5.

19,677. P. R. de F. d'Humy. Improvements in the manufacture of fuel briquettes. Sept. 5.

19,691. B. Parkin and W. S. Pickering. A new or improved method of enriching gas for illuminating and for other purposes. Sept. 5.

19,711. J. Steiger. Improvements in the manufacture of artificial fuel. Sept. 7.

19,841. E. M. T. Boddam. An improved method of and apparatus for producing gas for purposes of propulsion. Sept. 8.

19,953. G. Kremer. Improvements in the production by the cold process of gas for lighting and motive power, and apparatus therefor. Sept. 9.

19,957. H. Wellstein. An improved process of manufacturing mantles for incandescent burners. Complete Specification. Sept. 9.

19,973. P. Bode. Improvements in incandescent gas burners. Complete Specification. Sept. 9.

19,979. A. Rolf. Improvements in or connected with incandescent gas lights. Complete Specification. Sept. 9.

20,029. J. L. Shepherd. A new and improved method of protecting "Welsbach" incandescent or other incandescent or hollow flame gas lights. Sept. 10.

20,074. G. W. Gaskell and R. R. Gibbs. Improvements in or relating to the generation and storage of acetylene. Sept. 10.

20,083. W. W. Hughes and S. Willson. Improvements in generators for acetylene gas. Sept. 10.

20,084. W. W. Hughes and S. Willson. Improvements in or relating to the treatment or utilisation of peat and its products. Sept. 10.

20,090. E. Chesnay and L. Pillion. Improvements in apparatus for generating and storing acetylene gas. Filed Sept. 10. Date applied for Feb. 13, 1896, being date of application in France.

20,104. B. van Dyken. Improvements in apparatus for the manufacture and utilisation of acetylene gas. Sept. 11.

20,130. D. Waddell, A. Waddell, and F. Waddell. Improvements in the means of assisting combustion of fuels consuming smoke and in the more effective application of heat therefrom. Sept. 11.

* See Note (*) on previous page.

20,125. W. Young, S. Glover, and T. Glover. Improvements in the manufacture of illuminating gas. Sept. 11.

20,156. P. R. de F. d'Humy. Improvements in or relating to the manufacture of fuel. Sept. 11.

20,216. W. Watson and R. Hudson. An improved system of and means for illuminating. Sept. 12.

20,225. P. Fritzsche. Obtaining ether from gases containing ethylene and apparatus therefor. Sept. 12.

20,238. H. Turner and W. Allen. Improvements in or applicable to smoke-burning apparatus. Sept. 12.

20,251. E. Chesnay and L. Pillion. Improvements in apparatus for generating and storing acetylene gas. Filed Sept. 12. Date applied for Feb. 25, 1896, being date of application in France.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

16,716. W. Darby, I. Darby, and J. H. Punchard. Method and means of burning liquid hydrocarbons in conjunction with an incandescent hood or mantle to produce an incandescent oil burner. Sept. 9.

19,771. J. C. Bayley. Method and apparatus for generating and regulating the consumption of acetylene gas. Aug. 26.

20,453. J. H. Exley. Apparatus for generating acetylene gas. Sept. 9.

20,468. J. F. Atkinson. Automatic apparatus for the manufacture of acetylene gas. Sept. 9.

20,667. N. Notkin. Method and apparatus for automatically and continuously carburetting air for illuminating and heating. Sept. 2.

20,727. J. H. Exley. Apparatus for generating acetylene gas. Sept. 9.

21,089. J. McL. McMurtrie and Lucal Lim. Apparatus for the burning of fluid hydrocarbons for lighting and heating purposes. Sept. 16.

1896.

5976. E. Appieby and H. F. Harris. Apparatus for automatically and safely generating and storing acetylene. Sept. 2.

8509. P. G. de Schodt. New or improved system and means of illuminating and heating applicable with gas and mineral oils. Sept. 2.

10,372. E. Andreoli. Apparatus for the production of ozone. Sept. 2.

14,448. N. Caro and W. Saulmann. Manufacture of incandescent bodies, or mantles, for lighting purposes. Sept. 16.

16,425. G. Shenton and D. A. F. de Villepigne. Means for vaporising and burning liquid fuel. Sept. 16.

17,194. W. L. Voelker. Materials for incandescent mantles and processes for manufacturing the same. Sept. 9.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

18,221. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik. Improvements in the manufacture and production of phthalic and sulpho-phthalic acids. Aug. 17.

18,489. H. R. Vidal. Improvements in the manufacture of sulphuretted colouring matters. Aug. 20.

18,720. T. R. Shillito.—From J. R. Geigy and Co. Improvements in the production of red colouring matters. Aug. 24.

19,174. W. S. Simpson and Brooke, Simpson, and Spiller, Limited. Improvements in colouring matters. Aug. 31.

19,516. O. Imray.—From The Society of Chemical Industry in Basle. Manufacture of colouring matters of the group of the rhodamines and of rhodol. Complete Specification. Sept. 3.

19,831. S. Pitt.—From L. Cassella and Co. Production of black colouring matter. Sept. 8.

19,946. R. Blank. A process for the manufacture of compounds of the series of the indoxyl acids and of dyestuffs of the indigo series. Sept. 9.

19,976. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Manufacture of basic diazo colouring matters. Sept. 9.

20,250. B. Willeox.—From The Badische Anilin and Soda Fabrik. The manufacture and production of colouring matters from dinitro-naphthalenes. Sept. 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

15,836. A. Welter. Process for producing the salts of aniline and its alkyl derivatives, and of all its homologues. Aug. 26.

20,313. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Manufacture of azo dyestuffs from new *m*-nitraniline sulphonic acid. Sept. 9.

20,944. A. G. Green and H. Benfey. Treatment of technical nitro-toluene. Aug. 26.

21,342. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Manufacture of new triazo colouring matters. Sept. 9.

21,919. H. H. Lake.—From Farbwerk Muhlheim. Manufacture of sulpho acids of the naphthalene series, and of colouring matters derived therefrom. Sept. 2.

22,114. O. Imray.—From P. Reny. Manufacture of azo, diazo, and polyazo colouring matters with phenylene and toluylene oxamic acid. Sept. 9.

1896.

15,493. G. Cerekel. Preparation of ortho-sulphamine benzoic acid. Aug. 26.

17,293. M. Lange. Process for the manufacture of intermediate compounds containing two diazo groups. Sept. 9.

V.—TEXTILES, COTTON, WOOL, SILK, ETC.

APPLICATIONS.

18,360. F. N. Turney. Improvements in apparatus for degreasing wool, cotton waste, and other fibrous materials. Aug. 19.

18,517. W. J. A. Donald. See Class XIII.

18,555. G. T. Oliver. Improvements in the preparation of material or composition for waterproofing or ornamenting the surface of fabrics. Aug. 21.

18,693. J. Crossley and Sons, Lim., and J. Brooks. Improvements in the manufacture of cotton yarns or threads. Aug. 24.

18,701. C. D. Abel.—From C. Grenert. Process and apparatus for the manufacture of imitation lace, embroidery, and the like. Aug. 24.

19,217. A. Moorforts. Improvements in machines for finishing yarn in the form of hanks or skeins. Aug. 31.

19,951. J. McCreath. Improvements in wool drying. Sept. 9.

19,954. P. A. Newton.—From A. Nobel. Improvements in the manufacture of artificial silk. Sept. 9.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

- 20,669. F. Walton. Manufacture of floor-cloth. Sept. 9.
20,670. F. Walton. Manufacture of mosaic floor-cloth and apparatus therefor. Sept. 9.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

- 19,128. J. Schneider. Improvements in the treatment of fibres and fibrous or textile materials to improve the appearance or finish and facilitate the operation of dyeing. Sept. 2.
19,950. M. Beraud. Improvements in dyeing animal and vegetable fibres. Sept. 9.
20,208. G. M. L. Irvine-Moore. A substance to displace bitartrate of potash in wool and silk, &c. dyeing. Sept. 12.

COMPLETE SPECIFICATION ACCEPTED.

1896.

3058. W. Hepworth-Collins. Improvements in machinery and process for scouring, bleaching, dyeing, and otherwise treating yarn and other spun fibrous materials in cops or in similar compact forms. Sept. 16.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

- 18,239. M. N. d'Andria. Improvements in and connected with the manufacture of magnesium sulphate. Aug. 18.
18,468. I. Quirin. Proceeding for cleaning carbonic acid. Aug. 20.
18,589. J. Hargreaves and R. Armstrong. Improvements in the manufacture and treatment of detergent and bleaching compounds, and in apparatus employed therein. Aug. 22.
18,953. H. W. Smith. Improvements in the manufacture of cyanide of potassium. Aug. 27.
19,041. K. Jung and B. Steuer. Improved process and apparatus for regenerating chlorine. Aug. 28.
19,222. J. Y. Johnson.—From The Chemische Fabrik Electron Actien Gesellschaft. Improvements in the treatment of bleaching powder to preserve it from loss of active chlorine. Aug. 31.
19,364. W. Cooper. Improvements in treating brine. Sept. 2.
20,068. W. R. Clarke and The United Alkali Co., Lim. Improved means for effecting the absorption of chlorine gas, applicable in the manufacture of chlorates and bleaching liquor. Sept. 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

- 16,257. B. Hargreaves. Manufacture of chlorates, and means and appliances therefor. Sept. 2.
19,445. H. S. Elworthy and P. D. Henderson. Manufacture of carbonic acid gas by the utilisation of waste product produced in making calcium carbide. Aug. 26.
19,692. A. R. Davis. Apparatus for the manufacture of salt. Sept. 16.

1896.

- 13,881. W. R. King and F. Wyatt. Process for the manufacture of calcium carbide. Sept. 9.

VIII.—GLASS, POTTERY, AND ENAMELS.

APPLICATIONS.

- 18,581. W. Maguire. Improvements in the method of decorating tiles and hollow-ware. Aug. 22.
18,729. G. Alefeld. Improvements in the production of metallic lustre on glass, porcelain, and the like. Aug. 24.
19,123. H. Kunze. An improved printing process for producing metallic decorations on earthenware, glass, and the like. Complete Specification. Aug. 29.
19,746. F. Hancock and C. B. Winzer. Apparatus for pottery purposes. Sept. 7.
19,906. A. Roland. An improved process for ornamenting surfaces of pottery, glass, and the like. Sept. 9.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

- 18,295. J. F. Kleine. Improvements in fireproof ceilings and floors. Aug. 18.
18,622. G. F. Thomson. Improvements in the manufacture and treatment of artificial and other stone roofing and other tiles and enamel, and in apparatus therefor. Aug. 22.
18,714. From J. Jungbluth. Improvements in artificial stone for street pavements, pathways, and like purposes, and in the method of producing the same. Complete Specification. Aug. 24.
18,990. A. J. Boulton.—From Tortorici and Grasso. Improved process and apparatus for the treatment of articles of cement, plaster, chalk, and the like. Aug. 27.
19,001. J. A. Yeadon. Improvements in the manufacture of cements or other analogous materials. Aug. 28.
19,047. A. L. C. Nodon and L. A. Bretonneau. A new or improved process and means for drying or senilising wood. Aug. 28.
19,079. E. S. Flian. Making and burning cements, limes, &c. Aug. 29.
19,213. C. H. M. Lyte. Improvements in mosaic tile, cement parquet, and like flooring or pavement. Aug. 31.
19,419. A. McLean. Improvements in artificial stone. Sept. 2.
19,936. J. Steiger. Improvements in the manufacture of artificial stone, preservative paint, and other analogous materials. Sept. 9.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

- 16,661. J. Thomlinson. Manufacture of plaster, cement, mortar, and the like from chalk. Sept. 9.
21,295. O. Schwarz. A material suitable for use in building and the like, and means for manufacturing the same. Aug. 26.
22,873. O. Schwarz. Improvements in the formation and connection of plates or blocks for building purposes, and apparatus for manufacturing the same. Sept. 16.

1896.

- 16,136. J. Leuba. Paving blocks. Sept. 16.

X.—METALLURGY, MINING, Etc.

APPLICATIONS.

- 18,276. H. H. Lake.—From H. Schweitzer and E. E. Lungwitz. Improvements in the production of steel and in the refining of iron ore. Complete Specification. Aug. 18.

18,417. C. Phillips. An improved dry process or method for ore-dressing and gold-separating, and apparatus for same. Complete Specification. Aug. 19.

18,494. F. Ellershausen. Improvements in the treatment of complex sulphide ores. Aug. 20.

18,537. J. Ducot. Apparatus intended to determine the quantity of metal which a galvanoplastic bath should deposit on the object treated. Aug. 21.

18,616. J. Legge. Improvements in puddling and other like furnaces. Aug. 22.

18,620. W. Jordan.—From F. N. Blanc and T. S. Crane. Improvements in process and apparatus for protecting iron and steel ships from fouling by a copper coating. Aug. 22.

18,750. J. Y. Johnson.—From B. Hall. Improvements in solutions for hardening iron and steel. Aug. 25.

18,760. F. O'C. Prince. Improvements in means for introducing, diffusing, and regulating the air blast to cupolas for melting metal. Aug. 25.

19,178. J. Shanks. Improvements in moulds for casting. Aug. 31.

19,410. J. Lones and E. Holden. An improvement or improvements in the manufacture of buffer-iron or steel for the buffer barrels or cylinders of railway carriages, trucks, and waggons. Sept. 2.

19,640. W. van Wart, F. W. Poop, and J. J. Bradley. Improvements in the means for and method of producing certain kinds of metal especially adapted for use in the manufacture of the tubes and other of the component part of cycles of all kinds, autocars, and other wheeled vehicles, which improvements are also applicable for other industrial purposes. Sept. 5.

19,718. G. Bennett. Improvements in ingot moulds for the casting of ingots of iron, steel, or other metals, such as iron or steel alloys. Sept. 7.

19,883. E. Fischer and C. G. Penney. Improvements in apparatus for extracting metals. Complete Specification. Sept. 9.

20,131. W. Roberts. Improvements in and machinery or appliances for the manufacture of plates and sheets of copper, brass, and German silver. Sept. 11.

20,253. J. S. Wallace and J. Castell-Evans. A new or improved method of obtaining metals and other elements from ores or substances containing them. Sept. 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

13,072. C. Rainey. Dry concentrators for the treatment of ores. Sept. 16.

14,166. A. C. J. Charlier. Process for the volatilisation of galena into white compounds of lead, and of zinc into white compounds of zinc, the making of litharge, and the smelting of metals from their ores or slags. Aug. 5.

16,634. J. S. MacArthur. Obtaining precious metals from solutions. Sept. 9.

17,190. H. R. Lewis and C. Gelstharp. Separation or extraction of copper, zinc, lead, silver, gold, and other metals from ores or compounds containing the same, and the recovery of chlorine used in the treatment of such ores or compounds. Sept. 16.

17,320. J. Woolford. Apparatus for collecting metallic fumes. Sept. 16.

19,265. J. G. Accles and J. Pinfold. Improvements relating to the working of aluminium and to apparatus therefor. Aug. 26.

20,440. R. I. Roman. Manufacture of tubes of aluminium and its alloys. Sept. 16.

21,186. R. I. Roman. Manufacture of a new aluminium alloy. Sept. 16.

21,699. J. Raine and B. W. Raine. A process for the utilisation of old steel rails or new rail crops without re-melting. Sept. 2.

1896.

15,542. W. H. Howard. Desilverisation of lead bullion. Sept. 2.

15,965. R. H. Peak. Process of converting ferric oxide into magnetic oxide of iron. Sept. 9.

17,074. T. Andrews. Apparatus for consolidating metallic scrap. Sept. 9.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

18,191. J. Brandt. Improvements in galvanic batteries. Aug. 17.

18,249. W. S. T. Martin and H. Weymersch. An improvement in the preparation of filaments for glow lamps. Aug. 18.

18,326. H. Weymersch. Improved preparations for accumulator plates. Aug. 19.

17,519. J. B. Whittemore. Improvements in or relating to electrical primary batteries. Complete Specification. Aug. 21.

18,570. F. Dannert. Improvements in electric batteries. Complete Specification. Aug. 21.

18,627. A. Heil. A depolarized galvanic element. Aug. 22.

18,628. J. F. Bachmann, A. Vogt, C. C. Weiner, J. Kirehner, and A. König. Incandescence body for electrical glow lamps and process of manufacture of the said body. Complete Specification. Aug. 22.

18,648. R. Kennedy. Improvements in electrical storage or secondary batteries. Aug. 22.

18,951. A. Conder and E. P. Michelot. Improvements in electrical accumulators. Aug. 27.

18,974. J. L. Dobell. A new or improved apparatus for electrically smelting metals, and for other like purposes. Aug. 27.

19,045. A. Heil. Manufacture of secondary galvanic elements. Aug. 28.

19,218. E. J. Constam and A. von Hansen. Manufacture or production of chemical products by electrolysis. Aug. 31.

19,301. A. Preiss. Improvements in storage batteries. Sept. 1.

19,308. W. Walker, jun., F. R. Wilkins, J. Lones, and J. Lones. Improvements in utilising the residual products obtained in the working of certain kinds of voltaic batteries. Sept. 1.

19,505. H. Maxim. Improved methods and apparatus for electro thermally treating materials. Sept. 3.

19,877. D. G. Fitzgerald. Improvements in connecting the plates or elements of voltaic cells and batteries. Sept. 8.

20,035. D. Mathieu. Improvements in electrical batteries. Sept. 10.

20,061. J. A. Sinclair. Improvements in the manufacture of filaments for electric lamps. Sept. 10.

20,062. J. A. Sinclair. Improvements in the manufacture of filaments for electric lamps. Sept. 10.

20,077. T. F. Boland, C. J. Hubbell, and H. C. Hubbell. Improvements in and relating to primary batteries. Complete Specification. Sept. 10.

20,106. S. A. Rosenthal.—From S. J. Von Romocki. Improvements in secondary batteries. Sept. 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

16,557. E. Andreoli. Electro-deposition of gold and silver. Sept. 9.

16,569. L. Epstein. Manufacture of electrodes for voltaic batteries. Sept. 2.

17,063. T. L. Willson. Electric smelting. Aug. 12.

18,487. J. Heibling. Electrolytic manufacture of ferro-manganese, ferro-chrome, ferro-aluminium, ferro-nickel, and other alloys having an iron base. Sept. 9.

19,442. A. Hirsch. Improved method and apparatus for welding by electricity and for other purposes. Aug. 26.

19,745. J. Korner. Manufacture of plates for electric accumulators or secondary batteries. Sept. 16.

21,283. A. S. Elmore.—From J. O. S. Elmore. Electro-depositing of metals. Sept. 16.

1896.

3712. F. Monterde, C. Chavant, and J. George. Improvements in electro-accumulators. Sept. 16.

16,726. F. W. Schneider. Electrodes for secondary batteries. Sept. 16.

XII.—FATS, OILS, AND SOAP.

APPLICATIONS.

18,478. W. H. Caird.—From A. Delisser. Improvements in the manufacture of mottled soap. Aug. 20.

18,940. F. Sahlfeld. A process of obtaining sebacic acid from wool or fulling grease. Complete Specification. Aug. 27.

19,257. F. M. Sanders and The Digby Patents Co. An improvement in the manufacture of soaps. Complete Specification. Sept. 1.

19,903. H. Hadfield. Improvements in the manufacture of soap and in the frames used in the manufacture of soap and in the method of cutting or "slabbing" soap. Sept. 9.

COMPLETE SPECIFICATION ACCEPTED.

1895.

19,021. J. W. Barclay. Manufacture of soap. Sept. 2.

XIII.—PAINTS, PIGMENTS, VARNISHES, RESINS, INDIA-RUBBER, Etc.

APPLICATIONS.

18,485. W. Morison. Improvements in acid-proof electrical non-conducting articles and composition therefor. Aug. 20.

18,517. W. J. A. Donald. Improvements in and relating to the impregnating of materials with india-rubber, gutta-percha, and the like. Aug. 21.

18,864. D. Forbes and J. S. Weymouth. A gelatinous resilient composition applicable for wheel tyres and other purposes. Aug. 26.

19,046. Siemens Bros. and Co., Ltd., and E. F. A. Obach. Improved process and apparatus for the extraction of gutta-percha from the leaves and twigs of the *Lonandra* Gutta and kindred plants. Aug. 28.

19,310. J. Wetter.—From M. Weinrich. Process for revivifying bone black or animal charcoal. Sept. 1.

19,318. G. W. N. Hamilton. An enamel paint and combination of materials for composing same. Complete Specification. Sept. 1.

19,788. A. C. J. Charlier. Improvements in the manufacture of white lead. Sept. 8.

19,936. J. Steiger. See Class IX.

20,020. E. Wood. Improvements in quick-drying paints and varnishes. Sept. 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

21,175. J. Noad. Method and means of producing lead oxide. Sept. 9.

22,460. O. H. Hamilton. Production of basic carbonate of lead or "white lead." Aug. 26.

1896.

11,210. H. L. Haas. Polishing compositions. Aug. 26.

13,886. W. P. Tatham and W. Tatham. Manufacture of white lead. Sept. 2.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATIONS.

18,278. W. P. Thompson.—From B. Trenekmann. An improved process for tanning skins. Aug. 18.

20,154. R. W. James.—From S. Alimonda. An improved process for the tanning of skins. Complete Specification. Sept. 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1896.

5644. J. A. McIntosh. An improved method of treating hides and skins, &c. Sept. 2.

15,044. F. E. Burlingame. Manufacture of leather. Sept. 2.

17,370. E. E. E. Martens. A new or improved process for the preparation of liquid glue for joiners, upholsterers, and the like. Sept. 16.

XV.—AGRICULTURE AND MANURES, Etc.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

20,203. R. Silcock. Preparation or treatment of bones and mineral phosphates for fertilising purposes. Sept. 2.

1896.

15,473. E. Paternotte. Chemical manure mixers and the like. Aug. 26.

XVI.—SUGARS, STARCHES, GUMS, Etc.

APPLICATIONS.

19,815. G. Ranson. An improved process for refining and purifying sugar. Sept. 8.

19,825. M. von Schmidt and R. C. Wiener. A process to dissolve gum which is otherwise indissoluble. Sept. 8.

COMPLETE SPECIFICATION ACCEPTED.

1896.

17,195. J. A. Link. Improvements in and relating to adhesive compounds. Sept. 9.

XVII.—BREWING, WINES, SPIRITS, Etc.

APPLICATIONS.

18,423. C. W. Ramsay. Improvements in the preparation of distilled beverages. Aug. 20.

18,624. F. Hannao. Improvements in or relating to the manufacture of malt and to kilns therefor. Aug. 22.

18,639. F. G. Powell, A. Powell, M. E. W. Powell, and R. H. R. Powell. Improvements in the manufacture of beer wort gyle or the fluid from which drinkables are made. Aug. 22.

19,245. S. E. Field. Improvements relating to malting. Sept. 1.

19,252. J. W. Crichton. A new or improved apparatus for keeping whiskey and other liquids cool. Sept. 1.

19,317. W. T. Clark. Improvements in the process of manufacturing and bottling beer and apparatus therefor. Sept. 1.

19,616. K. Pattermann. Improvements in or connected with the germination of barley and apparatus therefor. Sept. 1.

COMPLETE SPECIFICATION ACCEPTED.

1896.

9923. H. Gronwald. New or improved process and apparatus for increasing the stability of beer and other liquids containing carbonic acid. Sept. 2.

XVIII.—FOODS, SANITATION, Etc., AND DISINFECTANTS.

APPLICATIONS.

A.—Foods.

18,275. L. G. Fagersten and C. F. P. Korssell. An improved process of sterilizing or pasteurizing milk and cream. Complete Specification. Aug. 18.

19,675. J. E. Duke. Improvements in the manufacture of liquid extracts of coffee or other substances and in apparatus for the purpose. Sept. 5.

B.—Sanitation.

18,444. F. P. Candy. Improvements in apparatus for use or in connection with the purification of sewage and polluted water. Aug. 10.

19,189. E. Green. New or improved apparatus for the mechanical treatment of sewage. Aug. 31.

C.—Disinfectants.

20,246. H. Hiscott. The manufacture of an improved disinfectant or composition for antiseptic disinfecting, sanitary, and other purposes. Complete Specification. Sept. 12.

COMPLETE SPECIFICATIONS ACCEPTED.

A.—Foods.

1895.

15,852. W. C. Kaufmann. Carbonated milk. Aug. 26.

17,061. S. D. Rowland. Concentrating alimentary or pharmaceutical liquids or other substances, and apparatus therefor. Sept. 2.

22,968. A. E. Cole. Improvements in Swiss or condensed milk. Sept. 16.

B.—Sanitation.

1895.

19,360. H. J. N. Berge. Processes and apparatus for the purification of drinking water. Aug. 26.

1896.

15,611. W. G. Waterman.—From L. Alers-Haukey. Apparatus for purifying water. Aug. 26.

16,034. E. W. Ives. Apparatus for the treatment of sewage and other liquids. Sept. 9.

C.—Disinfectants.

1895.

19,814. E. W. Rowsell and C. Stansfeld. A crystal carbolic disinfectant and deodorant powder. Sept. 9.

XIX.—PAPER, PASTEBOARD, Etc.

APPLICATION.

18,265. M. Honig. Improved manufacture of tannin-extract from sulphite cellulose lyes. Complete Specification. Aug. 18.

COMPLETE SPECIFICATION ACCEPTED.

1895.

19,471. G. W. A. FitzGeorge and H. J. Brown. Rapid paper-coating process. Sept. 9.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

APPLICATIONS.

18,369. T. O. Kent. A new or improved essence of cocoa and the method of preparing the same. Aug. 19.

18,981. A. Koelliker. The manufacture of acid salts of piperazine and fatty acids, and the production therefrom of double salts of lithia and piperazine. Aug. 27.

19,603. P. Auchinachie. Improvement in the distillation of aromatic waters, such as elder-flower water, rose-water, and the like. Complete Specification. Sept. 4.

19,744. J. J. A. Trillat. Improvements in the production of formic aldehyde vapours. Filed Sept. 7. Date applied for Feb. 5, 1896, being date of application in France.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

17,061. S. D. Rowland. See Class XVIII. A. Sept. 2.

20,827. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. The manufacture of pharmaceutical substances. Sept. 2.

22,351. G. W. Johnson.—From C. F. Boehringer and Soehne. Manufacture or preparation of vanillin. Aug. 26.

1896.

11,538. A. Krefting. Method of treating seaweed to obtain valuable products therefrom. Sept. 2.

16,947. J. C. Mewburn.—From The Chemische Fabrik von Heyden Gesellschaft mit beschränkter Haftung. Improvements in mono-alkyl ethers of pyrocatechin and in the production of such ethers. Aug. 26.

16,162. J. C. Mewburn.—From The Chemische Fabrik von Heyden Gesellschaft mit beschränkter Haftung. New perfume and process for the manufacture of the same. Aug. 26.

XXI.—PHOTOGRAPHY.

APPLICATIONS.

19,726. W. Grunow. A new or improved apparatus for developing, fixing, and toning photographs. Complete Specification. Sept. 7.

20,080. A. C. Edwards. Improvements in means or apparatus employed in the manufacture of photographic films. Complete Specification. Sept. 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

15,935. A. Hill and A. A. Barratt. Obtaining photographs in true relief in gold, silver, and other metals. Sept. 2.

22,692. G. Koppmann. Light-proof coloured positive-paper. Sept. 16.

XXII.—EXPLOSIVES, MATCHES, Etc.

APPLICATIONS.

18,547. A. Nobel. Improvements in the manufacture of ordnance powder. Aug. 21.

19,071. H. Maxim. Improvements in the manufacture of smokeless explosive compounds. Aug. 28.

19,740. W. G. Hay. Improvements in and connected with explosive shells. Sept. 7.

20,069. W. P. Thompson.—From La Société des Explosifs Industriels. Improvements in the manufacture of explosives. Complete Specification. Sept. 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

THE JOURNAL OF THE Society of Chemical Industry: A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 10.—VOL. XV.]

OCTOBER 31, 1896.

[Non-Members 30/- per annum; Members
21/- per Set of extra or back numbers;
Single Copies (Members only) 2/6.

The Society of Chemical Industry.

Past Presidents:

Sir H. E. Roscoe, LL.D., V.P.R.S.	1881—1882.
Sir Frederick Abel, Bart., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
Dr. W. H. Perkin, F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Prof. James Dewar, F.R.S.	1887—1888.
Ludwig Mond, F.R.S.	1888—1889.
Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
E. Rider Cook	1890—1891.
Prof. J. Emerson Reynolds, M.D., D.Sc., F.R.S.	1891—1892.
Sir John Evans, K.C.B., F.R.S.	1892—1893.
E. C. C. Stanford	1893—1894.
Dr. T. E. Thorpe, LL.D., F.R.S.	1894—1895.
Thomas Tyrer	1895—1896.

COUNCIL FOR YEAR ENDING JULY, 1897.

President: Dr. Edward Schunck, F.R.S.

Vice-Presidents:

Chas. Dreyfus.	A. Gordon Salamon.
Dr. A. Dupré, F.R.S.	E. C. C. Stanford.
Prof. A. K. Huntington.	G. N. Stoker.
A. H. Mason.	Dr. T. E. Thorpe, F.R.S.
Boverton Redwood.	Prof. W. A. Fildes, F.R.S.
Sir H. E. Roscoe, F.R.S.	Thomas Tyrer.

Ordinary Members of Council:

George Beilby.	C. C. Hutchinson.
R. Forbes Carpenter.	Ivan Levinstein.
R. Le Neve Foster.	J. S. McArthur.
Oscar Guttman.	B. E. R. Newlands.
Douglas Herman.	Sir Robert Pullar.
David Howard.	Wm. Thorp, B.Sc.

With the Chairmen and Secretaries of Sections.

Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

Honorary Foreign Secretary:

Ludwig Mond, F.R.S.

General Secretary: Charles G. Cresswell.

Offices: Palace Chambers, 9, Bridge Street, Westminster, S.W.

THE JOURNAL.

Publication Committee:

The President.

NOTICES.

COLLECTIVE INDEX.

A collective index, embracing the whole Journal from the Proceedings of the First Annual General Meeting, 1881, to the close of 1895, is now in preparation, and will be ready about the end of the current year. It will contain both a subject-matter and authors' names portion and will be a volume of about 500 pages, uniform in size with the Journal.

The prices will be as follows:—

To Members (see Rules 25 and 27) and Past
Members (see Rule 30); Libraries, Corpora-
tions, and Exchanges on the Society's List.

Each copy 10s.

To Subscribers	12s. 6d.
To others.....	18s.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPORTSWOOD, the Society's printers and publishers, to whom all communications respecting them should be addressed. The circulation of the Journal is now more than 3,000 per month.

Foreign and Colonial Members are reminded that the subscription of 25s. for 1897, payable on January 1st next, should be sent in good time to the Treasurer, in order to ensure continuity in the receipt of the Society's Journal. Any changes of address to appear in the new List of Members now in course of preparation, should reach the General Secretary not later than January 15th, 1897.

LIST OF MEMBERS ELECTED 23rd OCTOBER 1896.

Burland, R. O., Bishopgate, Wigan, Manufacturing Chemist.
Geisenheimer, Theodor, 189, Front Street, New York, U.S.A., Chemical Merchant.
Green, Jno. Wilberforce, 8, Clifton Terrace, Hayle, Cornwall, Technical Chemist.
Hall, Henry Jas., 51, Malnesbury Road, Bow, E.
Haylock, Edw. Geo., Rainham, Essex, Cement Manufacturer.
Hoyte, Percy S., Gas Works, Coxside, Plymouth, Gas Engineer.
Lester, Isaac E., Jamalpur, E.L.R., Bengal, India, Steel-works Manager.
Lewis, Daniel C., 574, Columbia Avenue, Millville, N.J., U.S.A., Dye and Bleach Chemist.
Marquart, Dr. Paul, Chemische Fabrik Bettenhausen, Bettenhausen, Cassel, Germany, Chemical Manufacturer.
Miles, G. Wellington, jun., 103, Milk Street, Boston, Mass., U.S.A., Analytical Chemist.
Murray, Dr. Thos. S., Chemical Department, The University, Aberdeen, Assistant to Professor of Chemistry.
Newcomen, Thos., Chemical Works, Lydbrook, near Ross, Wood Distiller.
Pennington, Alf. J., 8, Church Street, Hanley, Staffordshire, Technical Chemist.
Royal-Dawson, H., Sulphide Corporation, Ltd., Cockle Creek, Newcastle, N.S.W., Chemist.
Rudlock, Fred G., 19, Stanley Street, Warrington, Analytical Chemist.
Sauer, Dr. Ewald, c/o Max Kaehler and Martini, Wilhelmstrasse 50, Berlin, W., Chemist.
Seyler, Clarence A., Technical Institute, Nelson Terrace, Swansea, Analyst and Assayer.
Smith, J. Kent, The Cottage, Glascoed, near Wrexham, Metallurgical Chemist.
Snowdon, Charlie, 269, West Ferry Road, Millwall, E., Chemical and Oil Works Manager.
Snowdon, Jno., jun., Snowdon, Sons, and Co., Millwall, E., Chemical and Oil Manufacturer.
Takagi, Tamutaro, c/o Sumitomo, Kobé, Japan, Chemical Engineer.
Van der Linde, Harold, Guttapercha and Rubber Manufacturing Co., 61, Front Street West, Toronto, Canada, Chemist.
Yarrázaval, M. Francino, Calle San Antonio 14n, Santiago, Chile.

CHANGES OF ADDRESS.

Austen, Prof. P. T., 10 President Street; 99, Livingston Street, Brooklyn, N.Y., U.S.A.

I.—PLANT, APPARATUS, AND MACHINERY.

PATENTS.

Concentrating Liquids, Process and Apparatus for. L. M. H. R. Baudoin and P. E. L. Schribaux, Paris. Eng. Pat. 15,958, Aug. 24, 1895.

A process for concentrating wine or similar liquids, is described. It consists in vaporising the volatile components of such liquid, so as to reduce them to an extract; in condensing separately and successively the water and alcoholic vapours; and in mixing the condensed alcoholic vapours with the extract. The apparatus consists of an evaporator, a serpentine coil to condense the steam, a receiver heated by a steam coil so as to enable the condensed water to be reconverted into steam when desired, an alcoholic vapour condenser, an alcohol extraction pump, and a mixing chamber, wherein the alcohol and extract are mixed.—R. A.

Heating, Evaporating, and Concentrating Infusions and Liquids, Impts. in Means or Apparatus for. A. M. Huggill, J. Overton, and R. H. Catley, Liverpool. Eng. Pat. 19,103, Oct. 11, 1895.

Is apparatus for heating, concentrating and evaporating infusions, the patentee uses a steam or otherwise heated tray, inclined at an angle. This tray is constructed of a series of tubes, through which the heating medium circulates.—R. A.

Cooling Liquids, Impts. in, and Apparatus connected therewith. W. T. Ramsden, Middlesex, and A. G. Southby, Forest Gate, Essex. Eng. Pat. 19,782, Oct. 22, 1895.

This invention relates to improvements in apparatus for cooling liquids, such as water, or wort, by exposing them on surfaces exposed to currents of air. The liquid is made to fall in a shower or spray within a vessel through which air is drawn or forced, in an upward direction, by means of an exhauster, air propeller, or other suitable appliance. A series of perforated trays are fixed horizontally alternately to opposite sides of the vessel crosswise, so that, while the liquid falls vertically through the trays, the air is caused to pass between the trays, and through the falling liquid.—R. A.

* Any of these specifications may be obtained by post by remitting 8d.—the price now fixed for all specifications, postage included—to Sir Henry Reader Lack, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C.

Liquids of Different Densities, New and Improved Means and Apparatus for bringing into Intimate Contact. J. G. Calvert, Gothenburg, Sweden. Eng. Pat. 16,137, Aug. 28, 1895.

An apparatus is described for intimately mixing together liquids of different densities. It consists of a vessel provided with agitating, mixing, and churning devices and also means for admitting the heavier liquid in regulated quantity "into the upper part" of such vessel, and for withdrawing it at the lower part, and also means for admitting the lighter liquid, in regulated quantity, "into the lower part" of the vessel, and withdrawing the resulting liquid at the upper part of it.—R. A.

Means for facilitating Contact between Liquids and Gases for the Purpose of obtaining Reactions. O. Guttman, London. Eng. Pat. 14,774, July 3, 1896.

The towers, wherein reactions between gases and liquids are usually effected, are filled with hollow bodies made of glass, earthenware, or other substance which will not

be acted upon by the gases or liquids used. The bodies are formed with openings a^2 , provided with short internal necks, and may be corrugated, to increase their surface. In the figure, the direction taken by the gases is indicated by feathered arrows, and that taken by the liquid by unfeathered arrows, a portion of the liquid being retained in the recesses a^2 round the internal necks.—R. A.

[Salts, &c.] *Purifying Centrifugally-Separated Substances. A New and Improved Process for.* A. Rohrbach, Erfurt, Germany. Eng. Pat. 15,485, July 13, 1896.

The patentee states that instead of employing saturated steam, or a mixture of steam and air—which are liable to partially redissolve centrifugally-separated substances owing to the condensation of the steam—superheated steam, or a mixture of superheated steam and air, gives better results in a centrifugal machine. The temperature of the steam should be so regulated that it condenses only so much as is necessary to dissolve the impurities. The substance may be subjected to a preliminary purification, by washing it with a concentrated solution of the salt operated on.—R. A.

II.—FUEL, GAS, AND LIGHT.

Gas Works Purifiers, Revivification in. H. Termin. J. f. G.-beleuchtung, 39, [40], 650.

IN place of emptying the purifiers by hand every time it becomes necessary to revivify the oxide of iron, a hole 50 mm. wide is bored under the lowest floor in each, and connected with a discharge pipe leading to the chimney shaft. Back draught is prevented by a valve near the chimney, and each purifier is fitted with a separate cut-off valve.

The gas valves being closed, the ventilators are opened, and revivification is effected in the time otherwise occupied in emptying and refilling the purifiers. The necessary water is supplied by sprinkling the upper surface of the oxide of iron. Even after use six times over, the oxide does not obstruct the passage of the gas, but, as a precautionary

measure, the ordinary process of revivification is then adopted.

The temperature of the exhaust pipe should not exceed 40°C ., and is regulated by the taps affixed to the purifiers. The ill odour produced in the purifying house, when revivifying by steam, is destroyed by means of the hot gases in the retort furnaces.—C. S.

Acetylene, The Limiting the Explosive Proportions of, and Detecting and Measuring the Gas in the Air. F. Clowes. Brit. Assoc., Chem. Section, 1896.

THE value of acetylene as an illuminant, and the discovery of its ready production from calcium carbide, have led to the manufacture of this gas in some quantity; and acetylene will probably be dealt with in still larger volume in the near future. It becomes, therefore, important to devise methods of detecting its presence in the air, arising from leakage and escape, and to measure the percentage of the gas present at any place. It is also important to ascertain what proportions of the gas, when present in mixture with air, will lead to explosion if the mixture should be kindled.

The detection of small proportions of the gas will not be readily effected by its smell when it is prepared in a state of purity. At present the smell is made much more pronounced by the impurities which the commercial gas contains. Further, the smell will not in any case furnish a means of measuring the proportion present in the air. The method applied by the writer to the detection and measurement of fire-damp and coal-gas in the air, however, serves for detecting and measuring acetylene as well. A small hydrogen flame, set to either 5 or 10 mm. in height, as may be necessary, shows a pale but well-defined "cap" in air containing any proportion of acetylene below the lowest explosive proportion. When the hydrogen flame is exposed to the air to be tested for acetylene in a darkened space, it is at once tinged yellowish-green. The bluish pale cap has the following heights with varying proportions of acetylene, when the hydrogen flame is 10 mm. in height:—

0.25 per cent. gives 17 mm. cap.
0.50 " " 19 " "
1.00 " " 28 " "
2.00 " " 48 " "

When the hydrogen flame is reduced to 5 mm.:—

2.50 per cent. gives 56 mm. cap.
2.75 " " 79 " "

A convenient portable form of apparatus was shown by the writer, which enabled air to be passed readily over the standard hydrogen flame in a darkened vessel, and which quickly furnished the reading of the height of the cap.

In determining the limits of explosibility, when acetylene is mixed in gradually increasing proportion with air and kindled, the writer adopted a simple method, referred to at the last meeting of the Brit. Assoc. (1895). It was found that air must contain at least 3 per cent. of acetylene before it can be kindled by a flame and the mixture caused to burn throughout. As the proportion of acetylene is increased, the explosive character is augmented. When 22 per cent. of acetylene are present, carbon begins to separate during the burning. The amount of carbon which separates, increases until the explosive character of the mixture disappears. This point is reached when 82 per cent. of acetylene are present in the air.

The limiting percentages in air which are explosible, are accordingly as follows, and may be compared with those already determined by the writer for other combustible gases:—

Acetylene	3 to 82
Hydrogen	5 to 72
Carbon monoxide	13 to 75
Ethylene	4 to 22
Methane	5 to 13

It will be seen that acetylene gives a wider range of explosive proportions than any other of these gases does. Probably this is due to its endothermic nature, which leads to the gas being able to generate heat by its own decomposition. Heat thus generated would undoubtedly aid in causing explosion, and would thus extend the limits of explosive mixtures.

Welsbach Incandescent Light. Söhren. J. für Gasbeleuchtung, 1896, 39, [34] and [35], 545—550 and 561—566.

WHEN the Auer von Welsbach incandescent light first came before the public, about the middle of the year 1886, it gave an illuminating power of about 14 candles with an hourly consumption of 2.8 cb. ft. of gas, or 5 candle power per cb. ft. per hour. The mantles were composed of various mixtures of the oxides of zirconium, lanthanum, yttrium, magnesium, thorium, cerium, &c. They were so fragile and the illuminating power was so little better than that given by the ordinary burner, that it was not until 1891, when Welsbach had further perfected his invention, that the new light really attracted public attention. The illuminating power had then increased to about 50 candles, with an hourly consumption of 3.5 cb. ft., or 14 candles per cb. ft. per hour, and the mantles lasted for about 800 hours. A more recent development has been the alcohol incandescent lamp, suitable for districts where no gas supply is available.

The author discusses the various forms of burner used for incandescent gas lighting. The most noteworthy recent improvements consist in arrangements for regulating the air supply to the burner, and for effecting a very thorough mixture of the air and gas before the latter is burnt.

In making the mantle, a tubular-formed fabric of the purest cotton, free from ash, is used, and is first thoroughly purified by means of hydrochloric or hydrofluoric acid. It is then impregnated with "lighting fluid," consisting of a solution of the nitrates of the rare earths; and one end, which is to constitute the upper end of the mantle, is treated to another impregnation, either with the fluid or with solution of aluminium and magnesium nitrates, &c., in order to strengthen it. After drying, the upper end of the fabric is drawn together somewhat, by means of asbestos thread, the whole is suspended from a holder, and the cotton burned away, leaving a skeleton of the oxides. The average weight of an impregnated mantle is 5.123 grms.; after "burning off," 0.680 gm.; and the available surface is 54 sq. cm., of which 45 sq. cm. act as glowing surface.

According to Welsbach's first patent, mantles for emitting white light consist of various mixtures of lanthanum, yttria, zirconia, and magnesia, neodymia being added to produce yellow light, and ceria to produce greenish light. His second patent claims the use of thorium in such mixtures as the above, and the use of ceria to produce an intense yellow light; it also claims the use of niobates, tantalates, silicates, titanates, and phosphates of thorium, zirconium, and magnesium for strengthening the contracted part of the mantle, and the use of ammonium nitrate in the fluid to expedite the "burning off." A later patent claims the use of thorium mixed with uranium oxide in making mantles. According to Mackean (this Journal, 1891, 196), the individual pure oxides give, with a consumption of 3.0 cb. ft. of gas per hour, at a pressure of 1 in., the following results:—

Lanthana	22.5 candle power: light, white.
Zirconia	12.2 " " white.
Thorium	25.0 " " bluish white.
Yttria	19.8 " " yellowish white.
Ceria	4.0 " " nearly red.

It is therefore evident that the extraordinary illuminating power of the Welsbach light is not due to one of the oxides alone, but to certain mixtures of them.

The chief sources of the rare earths are *orthite* and *allanite*, containing 10—20 per cent. of cerous oxide, 3 per cent. of yttria, 10 per cent. of lanthana, some ceria, &c.; *gadolinite*, with yttria, lanthana, cerous oxide, ceria, &c.; *scenotime*, with 62 per cent. of yttria, 11 per cent. of cerous oxide, 27 per cent. of phosphoric acid; *eukenite*, with 31 per cent. of niobiac acid, 18 per cent. of yttria, 2 per cent. of cerous oxide, &c. (according to other analyses, containing still more Nb_2O_5 and Y_2O_3); *yttriotantalite*, with 19 per cent. of yttria, &c.; *ferugonite* and *tyrite*, with 48 per cent. of niobiac acid, 46 per cent. of yttria, and 4 per cent. of cerous oxide; *cerite*, with 13 per cent. of cerous oxide, and 8 per cent. of lanthana and didymia; *zircon*, with 57 per cent. of zirconia, tantallic acid, &c.; and *monazite*, with

cerous oxide, lanthana, &c. These minerals contain but little thorium, and are very scarce, and accordingly very expensive. Thorium was obtained at first from *thorite* and *orangeite*, which occur as small crystals scattered through Norwegian igneous rocks, and contain on an average 73 per cent. of ThO_2 , 17 per cent. of SiO_2 , and 10 per cent. of water. These minerals are, however, so extremely rare, as is also *aceschynite* (which contains 15 per cent. of ThO_2), that some other source had to be found to meet the demand for thorium. *Monazite* has met the want: it is a mineral occurring in large quantities in the gneiss and granites of the Brazilian coast and in the river sands of North and South Carolina and Canada. *Monazite* contains about 3 to 4 per cent. of ThO_2 , and the sand at present shipped to Europe consists of 70 per cent. of *monazite*, mixed with zircon, xenotime, ilmenite, magnetite, gravel, and organic matter. Drossbach found in Brazilian *monazite* 60–70 per cent. of cerous oxide, 0.5 to 1.5 per cent. of thorium, and erbia, with other oxides of the yttrium group. Fresh sources of *monazite* are continually being discovered, and the price of sand containing 70 per cent. of *monazite* is about 30*l.* per ton f.o.r. in N. Carolina, 37*l.* per ton f.o.b. New York, or 18*l.* per ton c.i.f. Hamburg.

Analyses of mantles made by the German Incandescent Gas Light Co. having shown that the prescriptions of Welsbach's patents were not being exactly followed, but that the mantles consisted chiefly of thorium, with about 1 to 2 per cent. of ceria, a great number of competing companies have been manufacturing mantles of similar composition, on the supposition that such prescriptions were not protected by Welsbach's patent, so that there are now about 74 manufacturers of incandescent burners in Germany. The prices have accordingly been much reduced, and in the endeavour to obtain a still cheaper form of mantle, Häfner has patented a combination of alumina and oxide of chromium. Much costly litigation has been entered upon by the competing companies in endeavouring to procure the revocation of Welsbach's patents, and the decision of the Supreme Court has turned out much to Welsbach's disadvantage.

The concluding part of this paper is devoted to a description of the author's experiments in choosing a suitable brand of incandescent burner for the gasworks at Bonn, and a general discussion on street lighting, bye-pass lighting, glass and mica chimneys, &c.—H. B.

Thorium Nitrate, Commercial Investigation of. The Separation of Thorium and Cerium. R. Fresenius and E. Hintz. *Zeits. Anal. Chem.* 1896, **35**, 525.

From the results of analyses of incandescent mantles and of commercial thorium nitrate, the following conclusions are drawn:—(a.) The mantles containing least ceria, are, nevertheless, appreciably richer therein than the most impure commercial thorium nitrate reputed to be richest in ceria. In the mean, the mantles examined contained 1 per cent. of ceria, which is about five times the amount found in the most impure thorium nitrate. (b.) Thus the ceria found in the mantles cannot be regarded as an impurity due to the use of commercial thorium nitrate, but must either, at least in part, have been added, or must occur in the mantles through the use, unintentional or not, of a correspondingly impure thorium nitrate rich in cerium.

The ratios of the two earths in the mantles varied between 2.02 grms. of ceria to 96.42 grms. of thorium, and 0.38 grm. of ceria to 28.91 grms. of thorium. By an analysis executed in the following manner on two mixtures of this composition, it was shown that such amounts of ceria can be separated. A solution containing 13.890 grms. of thorium and 0.2910 grm. of ceria, was diluted to 4 litres, and, after addition of sodium thiosulphate, heated to boiling. The precipitate was filtered off and washed, the filtrate precipitated by ammonia, this precipitate filtered, washed, dissolved in hydrochloric acid, and the solution evaporated. The residue was dissolved in water and a little hydrochloric acid, and the solution again boiled with thiosulphate, the small precipitate so obtained filtered off, the filtrate precipitated by ammonia, and the previous treatment repeated. Finally, the precipitate was dissolved in nitric acid, the solution evaporated, and the aqueous solution of the residue precipitated by oxalic

acid, the precipitate ignited and weighed. The cerium dioxide so obtained still contained 0.0021 grm. of thorium; after correcting for this, the weight of ceria found was 0.2852 grm., as compared with 0.2910 grm. taken. A similar result was obtained with a solution containing the earths in the other ratio given. (See this Journal, 1896, 675.)

The final conclusion is that thorium nitrate can now be prepared in a more pure state than that used in the manufacture of mantles, and that either cerium is added to the impregnating liquid or a thorium nitrate rich in cerium is intentionally employed.—A. C. W.

Petroleum: Raising the Flashing Point v. Improved Lamps. Chem. Rev. Fett- u. Harz Ind. **3**, [47], 177–183.

With reference to the objections that have been urged against the possibility of regulating the sale of "safe" lamps, the opinion is expressed that there could be little difficulty in prescribing that each lamp should be provided with a lengthened wick-duet, reaching to the bottom of the receiver and so cutting off communication with the external air. It is also pointed out that the use of high-test oil would, by reason of the decreased capillarity of the heavy oils, necessitate a modification of the lamps in the direction of shallower receivers, in addition to the provision of a stronger draught to ensure complete combustion.

An exception to the general rule that an increase in the flashing point is attended with a more rapid rate of decrease in the flame of the lamp, is afforded by an expensive "safety oil" sold in Austria, which, with a specific gravity of 0.778, has a flashing point of 41½° C. (Abel). This oil, however, in experiments made with a "Reform Kosmos" burner, giving a 70-mm. flame, was consumed at a greater rate per hour (40 grms.) than a Roumanian oil of sp. gr. 0.8295 and flashing point 21.5° C. (37 grms.), tested under identical conditions. A third oil (sp. gr. 0.826; flashing point 28.5° C.) burned at the rate of 37.5 grms. per hour. A Russian oil, also subjected to the same test, behaved as follows:—

(a.) Oil of sp. gr. 0.820 and flashing point 28.7° C. Consumption, 38 grms. per hour.

(b.) Same oil with 1 per cent. of benzine (0.763); sp. gr. 0.8195, flashing point 28.5° C. Consumption, 40.8 grms.

(c.) Same oil with 5 per cent. of benzine; sp. gr. 0.8187, flashing point 21° C. Consumption, 43 grms.

With the safety oil, the curve of illumination rose rapidly, and then remained fairly stationary, but in the case of the second and fourth oils, it declined after attaining the maximum.

The conclusion drawn by the writer is to the effect that light oils with high flashing point can but seldom, and heavy oils never, be burned in ordinary lamps, and that a reconstruction of the lamp being necessary, it may just as well be effected in such a manner that low-test oil can be burned with safety. Furthermore, in addition to the increased cost of high-test oil, the larger quantity burned per hour entails an additional expense on the consumer.—C. S.

Petroleum, Trial of, as Fuel for Boilers, with Movable Hearths, conducted at the Works of Wegher and Richmond, Ltd. L. Le Chatelier. *Bull. de la Soc. d'Encouragement*, 1896, **8**, 1169–1174.

The first trials were made with a boiler heated from a concentric movable combustion chamber of sheet iron,

Fig. 1.

protected internally by an arched lining of refractory bricks, and supplied with air through openings in a floor within the chambers, in which the bricks are arranged as shown in Fig. 1: air is also admitted to the fire space beyond the

Fig. 2.

movable chamber through orifices (Fig. 2) in the grill B. The chamber is constructed in two parts, 1.1 metre and 0.6 metre respectively in length, and the shorter part, being movable, admits of modifying the total length at pleasure. The grill had three ranges of thin bevelled bricks, arranged "en chicane," so that the air spaces admitted of ready adjustment, and also so that the direction of the air currents should be nearly at right angles to the jets of petroleum and steam. The boiler experimented with was one of a pair, coal being used in heating the other. The contents of the boiler was 4,450 litres, containing, at medium level, 3,450 litres of water. Crude American petroleum of 0.910 density was used. The burner was of the pulverising injector type (Fig. 3), the central tube A, contracted at its

Fig. 3.

opening, giving passage to steam, while petroleum, previously heated to 40°–50° C. by passage through a water-jacket kept at 100° by communication with one of the boilers, enters at B, mingling in the annular tube with the air entering at C. A metal deflector E, has a concave surface presented towards the jet, and facilitates the mixture of the petroleum and air. Another form of deflector in sheet-iron, a trapeze in vertical section, and widening towards the mouth, is also shown. The cistern containing the petroleum is placed at such a height as to give a pressure at the tuyère of 0.3 kilo. The tube conveying the petroleum is of 31 mm. internal diameter, and that carrying the steam is of 12 to 15 mm. diameter, and in part of its length the steam is superheated by passage through one of the tubes of the second generator, previously put under pressure. The total section of holes for admission of air to the chamber was 7 square decimetres for a chamber 1.5 metre long.

The results of a three hours' trial were that 10.25 kilos. of water were vaporised per kilo. of petroleum consumed. During this trial, the temperature in the furnace, behind the generator and above the register, was from 210°–235° C., and a constant pressure of 6 kilos. was maintained. In subsequent trials a better result was obtained by bringing the burner and its deflector nearer to a horizontal position than at first, a vaporisation of 12.6 kilos. of water per kilo. of petroleum consumed, at a rate amounting to 500 kilos. of water vaporised per hour, being attained. The temperature taken in the combustion chamber by the *Le Chatelier* pyrometer varied between 900° and 950° C.; the maximum attained at the back of the boiler was 250°. The corresponding temperatures for the companion boiler, heated by the combustion of coal, were respectively 800° and 226°.

The tube combustion chamber was afterwards shortened, by means of its movable piece, by 0.4 metre, and the section of air holes diminished to 5.5–6.0 square decimetres of total section, when it was found possible to increase the consumption of the petroleum up to 15 to 50 litres per hour, while the time necessary to raise the pressure in the boiler was reduced to little over an hour. These later trials gave a production of 511 kilos. of steam per hour, or 14.2 kilos. per square metre of heating surface, each kilo. of petroleum volatilising 12.3 kilos. of water. The highest temperature obtained in the hearth was 850°, and 230° to 235° at back of the boiler. The rate of combustion was regulated according to the character of the smoke issuing from the chimney; normally, a slight yellowish smoke, the appearance of any black smoke requiring correction. It was found necessary to place a filtering screen in the petroleum reservoir, to prevent clogging of the burner.

Conclusions.—It results from these experiments that, under the specified conditions of working, namely, the charge of petroleum, reheating, superheating, dimensions of the hearth, access of air, &c., it is possible to vaporise 12.5 kilos. of water per kilo. of petroleum. The volume of air required for the combustion, deduced from the chemical composition of the petroleum, may be taken as equal to 25 cubic metres per kilo. of the combustible, and the air openings of the ash-pit door and grill need to be so regulated as to obtain a speed of air current of between 4.5 and 6.5 cubic metres per second. It will be understood that these figures are not to be taken as absolute; that they depend upon the installation and the trials made as described, and they may be considerably modified under changed conditions, such as in working with apparatus of a different type, or even of similar type, but of different force. These results confirm preceding conclusions: that the vaporising power obtained with coal and with the heavy petroleum oils are sensibly proportional to the calorific power of these fuels, which is, roughly, in the relation of 1 to 1.5 for the case considered. In the course of the trials, 11,000 calories have been taken as the figure representing the calorific power of the petroleum oil used. Hence it may be seen that the utilisation, in per cents. of the total heat, is sensibly the same in both methods of heating, whether it be with coal or with the heavy petroleum oils.

A further trial is described with a semi-portable machine, No. 3, of 10 horse-power, in which the consumption of petroleum proved to be 1.785 kilos. per horse-power per hour, agreeing closely with an estimate previously made, based upon the usual consumption of coal in working the boiler.—E. S.

PATENTS.

Refractory Substances [Pencils for Arc Lights], Impts. in the Manufacture of, and Apparatus therefor. E. A. Pellet, Paris. Eng. Pat. 15,103, Aug. 10, 1895.

MAGNESIA, derived from strongly heated magnesium carbonate, is moulded under great pressure into blocks or pencils of suitable form, which are packed into a crucible in alternate layers with charcoal. The crucible, closely covered, is heated by the combustion of gas carbon or graphite in a furnace, the inner wall of which is built up of magnesium carbonate moulded into bricks, the outer wall being of fireclay bricks and the interval filled in with charcoal and covered with earth. After long-continued heating to the highest attainable temperature, the fire is allowed to die out, and the furnace is sealed until it is cold. The inner wall of magnesium bricks, after being thus heated, furnish the magnesia from which the pencils are moulded for the next charge. Magnesia blocks or pencils thus prepared are used in arc lamps in such manner that the carbous of a lamp bear against the magnesia block placed between them, the pressure being maintained by means of a weight or spring, thus dispensing with complex apparatus. —E. S.

Gas [from Coal, Coke, Petroleum, and Water], Impts. in the Manufacture of. T. G. McKwen, Leytonstone. Eng. Pat. 15,366, Aug. 15, 1895.

THE coal is fed into a closed furnace and passes down over two inclined planes, losing its volatile matter in transit, and falling into the fire below in the condition of coke. The vapours from a mixture of oily matters and water, heated in a saddle boiler over the fire, escape and mingle with the products of combustion in a brick chequer-work flue, whence they pass over the coal on the upper incline and effect its distillation. Thence they are led downwards through a second chequer-work of firebrick (on to which is sprayed hydrocarbon oil to further enrich the gas), then upwards through a third chequer-work, and down through a chequer-work pile of firebrick to the outlet. —C. S.

Fluid Hydrocarbons for Lighting and Heating Purposes [Vapour Burners], Impts. in and relating to Apparatus for the Burning of. P. C. Tennant, Bishopsgate, London, and A. H. Crockford, Dartford, Kent. Eng. Pat. 16,515, Sept. 3, 1895.

THE apparatus is designed to produce a vapour burner or "industrial lamp" which shall efficiently burn the lower grades of petroleum oils, such as heavy or crude petroleum, or tar oil from gasworks. Reference is made to two previous patents, Nos. 235 and 9305 of 1895. The vaporising chamber consists of tubes or passages which cross or intersect each other between the inlet and outlet passages, four pairs being illustrated. A wind guard or ignition tube is adjustably mounted between the nozzle jet and the vaporiser. The oil-supply vessel is arranged approximately at an angle of 15° to the axis of the burner head, being mounted in a tubular piece or chamber at the upper end of the stand pipe, so that it can be turned about its axis. —R. S.

Petroleum [Injection with Air and Superheated Steam] Burning Furnace. W. T. Chamberlain and C. B. Beebe, Boston, U.S.A. Eng. Pat. 14,465, June 30, 1896.

THIS invention relates to the feeding and distributing of oil in petroleum-burning furnaces, the oil as it enters the combustion chamber being mixed freely with air and superheated steam. The combustion chamber is supported within the boiler by a large number of hollow stay bolts, the outer ends of which are all connected to the oil-supply pipe, while the inner ends are preferably covered with very fine wire gauze. A pipe leads superheated steam from the dome to a small chamber beneath the combustion chamber. This small chamber is connected to the combustion one by hollow bolts, through the centre of which pass smaller tubes open externally to the atmosphere, whereby both superheated steam and air pass freely in fine streams into the combustion chamber, where they meet the oil sprays. —R. S.

Liquid Hydrocarbons, in Conjunction with an Incandescent Hood or Mantle, to Produce an Incandescent Oil Burner; Method and Means of Burning. W. Darby, J. Darby, and J. H. Punchard, all of Pentonville, London. Eng. Pat. 16,716, Sept. 6, 1895.

THE object of this invention is to modify an oil lamp so that it can be used with a Welsbach or like mantle. The oil is vaporised, and mixed with a large proportion of air before it reaches the mantle, where the full combustion takes place. To accomplish this, the usual circular wick has an inner and an exterior wick tube, with both of which it is in combination. Within the former of these wick tubes is a projecting perforated cylinder allowing air to pass to the wick from the central and air tube. Above the wick are two other perforated air tubes, one a little above and to the outside thereof, the other higher up and towards the centre. The latter carries a perforated rose, upon which the crutch supporting the mantle is placed. This arrangement and connection of wick with wick tubes, and perforated cylinders, and these with the air supply, is for the purpose of "producing and regulating, first, the partial combustion of the oil at the wick; and, secondly, the complete combustion within the mantle of the gases produced by such partial combustion." —R. S.

Bunsen Burners, Incandescent Burners, and the like; Impts. in. W. P. Thompson, Liverpool. From A. Baudsept, Brussels. Eng. Pat. 17,927, Sept. 25, 1895.

WITH the object of increasing the intimacy of the mixture of air and gas in the burner, and so abolishing the internal cold zone of the Bunsen flame, the inventor employs a series of fixed (gauze) or movable (fan) atomisers at the nozzle of the burner, and maintains the speed of the gas current by means of several tuyères of increasing size in the lower part of same, the air supply entering by way of a number of perforations in the surrounding wall of the burner.

For the purpose of incandescent lighting, a smaller supply of gas is admitted than for heating, and the tuyères are modified so as to obviate the destruction of the mantles by too excessive heat. —C. S.

Incandescing Mantles, Impts. in Materials [Magnesium Calcite] for, and Processes for manufacturing the same. W. L. Voelker, Elizabeth, New Jersey, U.S.A. Eng. Pat. 17,191, Aug. 4, 1896.

A SOLUTION of equivalent proportions of calcium and magnesium nitrate is evaporated to dryness and heated until decomposed. If a yellow tinge of light be desired, one-eighth of 1 per cent. of cerium nitrate is added to the original mixture; or to obtain a ruddy tinge, the same proportion of chromium nitrate. The mixed oxides are fused in an electric furnace having a thick interior lining of pure lime. The fused oxides flow into a mould or open vessel beneath, while the charge within the furnace descends by gravity towards the electrodes. The fused mass is finely ground and worked up with a viscous compound, and, after rolling, is subjected to prolonged pressure at about 110 F. It is then rolled into sheets or drawn into threads for forming mantles. A mixture of one part each of camphor and gun-cotton, and 40 parts of oil of cassia, with four parts of sulphuric acid, is made and forms the viscous material; one part of this mixture is combined with three parts of the calcium-magnesium oxides, and treated as described. —E. S.

Carbonic Acid Gas, Impts. in the Manufacture of, by the Utilisation of Waste Products produced in making Calcium and other Carbides. H. S. Elworthy, Bandra, Bombay, and P. D. Henderson, London. Eng. Pat. 19,445, Oct. 16, 1895.

Gas Producer [Gas from Smalls and Dust], An Improved. A. Clouard, Caen, France. Eng. Pat. 20,430, Oct. 29, 1895.

THIS producer is designed for the preparation of permanent combustible gases, chiefly from rich small and dust coal.

The principle of the method consists in the introduction of a current of steam and air at two different levels in the (vertical) furnace—one to maintain the combustion of the fuel, and the other to assist the distillation of the upper layers of coal. The products of distillation are returned through a side flue to the centre of the furnace, where, meeting the downward portion of the upper current, the tars, &c., are decomposed into permanent gases, and the whole of the products of distillation and combustion escape through a side outlet at a somewhat lower level. When the coal is very rich, a current of air is admitted into the furnace on the same level as the returned products of distillation, to assist in their decomposition by aiding the combustion of the coke at that level. The mass of coke formed in the upper section of the furnace continually requires breaking up—an operation effected by a stoking fork suspended in the head of the retort, and caused to descend automatically by a hydraulic arrangement (or other suitable means). Several modifications of the furnace and its appendages are given.—C. S.

Acetylene Gas, Impts. in Automatic Apparatus for the Manufacture of. J. E. Atkinson, Liverpool. Eng. Pat. 20,468, Oct. 30, 1895.

This invention relates to automatic apparatus for generating acetylene from calcium carbide, and consists of two generators communicating with a gas-holder, and each provided with a removable box to hold the carbide. The generators are independently connected, through regulating cocks controlled by the movement of the gas-holder, to a multiple-way cock for the water supply, having a port so shaped that the cock opens slowly as the gas-holder begins to descend, and rapidly afterwards. Communicating pipes and valves are so arranged that when the carbide in one generator is exhausted, the water automatically passes to the other freshly charged generator, after which the exhausted box may be emptied and refilled.—R. S.

Acetylene [New Generator] for Illuminating Purposes, New or Improved Apparatus for Producing and Consuming. A. H. J. Schülke, Berlin. Eng. Pat. 14,929, July 6, 1896.

The generator—forming the base of the lamp—consists of a water vessel containing a bell receiver, in which is suspended the carrier to hold the calcium carbide. The limit of ascent of the bell is determined by projecting stops on the outer vessel, and when this point is reached, any further gas disengaged, escapes through a central tube projecting through the bottom of the vessel and leading to a larger bell gas-holder, where it is stored, to be returned automatically as the pressure in the receiver diminishes.

The lamp is situated above the receiver.—C. S.

Calcium Carbide, An Improved Process and Apparatus for the Manufacture of [Electrical Furnace]. W. R. King and F. Wyatt, New York, U.S.A. Eng. Pat. 13,881, June 23, 1896.

In this process, finely pulverised lime and coke are used in about equal proportions and subjected to electrical action in the open air; or, to economise ground space, a furnace constructed as follows may be employed:—The furnace is open at the top and has vertical walls constructed of fire-brick, which need not be lined with protective material, as they are not subjected to great heat. Through the centre of the bottom of the furnace there projects up, a good-sized carbon stick, forming the negative electrode. The positive electrode is adjustably mounted on a swinging frame which stands at one side of the furnace. The powdered mixture of coke and lime is shovelled in to any desired height, and a conducting core formed of a fine carbon rod, is thrust down through the mass till it reaches the lower electrode. The upper electrode is lowered on to it, and the material is heaped up round the side of the electrode so as to prevent the access of air. On the passage of the current, the core is gradually burnt away and the electrode descends, and the process is stopped when the voltmeter readings show that a nugget of carbide has been formed. The nugget is removed to a distance to cool by a pair of grasping tongs thrust down into the mass, a fresh core is inserted, more material shovelled in, and the furnace is

started again, the action being practically continuous. In this process the incandescence principle is employed instead of the arc, and either a direct or an alternating current may be used.—G. H. R.

Liquid Fuel Stores or Furnaces, Impts. in. B. J. B. Mills, London. From P. Carmien, Montbéliard, and A. Yvonnet, Roanne, both in France. Eng. Pat. 19,505, Oct. 17, 1895.

The stoves, which may be applied to heat kitchen ranges, ovens, cauldrons, or for any other purpose, consist of:—1st. A reservoir containing the oil the vapour of which is to be burned at a greater or less distance therefrom. 2nd. A communication between the reservoir and the burner or burners, consisting of a tube of small diameter, or of several such tubes enclosed within a flexible sheath or covering, or twisted together as a cable. 3rd. A vaporising tube in which the liquid is vaporised. 4th. A stove or burner varying in shape according to requirements. 5th. A heater, transmitting to the vaporiser the amount of heat necessary for the vaporisation of the liquid.—R. S.

Distilling [Tarry Matters], Impts. in Means or Apparatus for; also applicable for Enriching Gases by Means of Hydrocarbons. P. Dvorkovitz, London. Eng. Pat. 18,877, Oct. 8, 1895.

See under III., page 706.

Coal-Gas, Enriching; Impts. in the Method and Means of. R. G. Shadbolt, Grantham, and J. W. Broadhead, Elland. Eng. Pat. 5051, March 6, 1896.

The inventors, making use of the property of the lighter vapours in gas of absorbing the heavier illuminating constituents, return some 10 per cent. of the partly purified gas into the crude gas at a point between the retorts and the condenser—the exact position of the delivery varying according to circumstances—at a temperature of between 120° and 130° F. The result is that the accession of purified gas prevents the deposition of some of the heavier vapours (which would otherwise be lost to the gas), its illuminating power being thereby increased. Provision is made for heating the returned gas when necessary (e.g., in cold weather).—C. S.

Illuminating and Heating, New or Improved System [Mixing and Burning] and Means of, applicable with Gas and Mineral Oils. P. G. de Schodt, Namur, Belgium. Eng. Pat. 8509, April 22, 1896.

The essential portions of the apparatus consist of three parts: an impeller, a mixer, and a burner. 1st. Taking the case of gas, it receives an impulse to "make it capable of attaining" high temperatures, by the use of a pump having two cylinders, the pistons moving in cylinders alternately placed in communication with the motor gas supply and with the atmosphere. The power required for working the pump mechanism to give the impulse or "momentum" referred to, may be derived from tubes containing liquefied carbonic acid, and is automatically distributed to the two cylinders by a slide-valve arrangement regulated by a pendulum or balancing lever having a tube containing mercury attached to it, such mercury, as it becomes displaced, forming a counter-balancing weight alternately at either end of the pendulum. The illuminating or heating gas then passes to a pressure reducer or regulator. Or a motor cylinder and a compressing cylinder may be mounted one over the other, the motor cylinder having a working piston, above and below which the motor gas is alternately caused to act, whereby the required impulse is given through the medium of the piston of a large compressing cylinder. 2nd. The mixer consists of one or more injectors, the orifices of which are situated so as to face one or more cylindrical or truncated nozzles, producing vortices, while there is also a thin plate, perpendicular or at right angles to the direction of the currents, and a contracted tubular portion of a paraboloid segment. 3rd. One or more burners are fitted on the mixing tube, and have the form of an inverted truncated cone, carrying one or more incandescence caps or mantles. When a number of

burners is employed, the gas first passes into an expansion cone beneath them. The products of combustion are caused to pass round the mixer, and the flame is deflected downwards to act upon a sleeve or mantle, which is shaped as a mushroom and is surrounded by a light structure or basket of platinum, thereby acting as a recuperator or light-restoring device. The compressing apparatus may be used for imparting to air the momentum necessary for carburetting it, by carrying it through hydrocarbons or mineral oil. The carburetted air passes through the same apparatus as above.—R. S.

Vapour or Gas, Injecting into Furnaces [Fuel], Impts. in Apparatus for. P. M. Justice, Chancery Lane, London. From H. F. Atkinson, Rochester, U.S.A. Eng. Pat. 15,757, July 16, 1896.

For preventing the production of smoke in furnaces, an arrangement is provided whereby, upon opening the furnace door, a blast of steam or of air, or of mixed air and steam, is turned on and distributed over the fire space, which blast continues after the stoking is finished and the furnace door shut, for the space of time for which the apparatus is set. The injector nozzle has a depending tubular cup connected thereto, placed within the furnace, into which water flows from a supply tank, and wherein it boils, thus preventing the nozzle being damaged by the direct heat of the furnace. —R. S.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

Petroleum in Oman, Borings for. A. Eyraud. Génie Civil, 29, [15], 235—237.

THE petroleum and bitumen springs in the neighbourhood of Ain Zeff appear along a line coinciding with the anticlinal axis of the mountain range, and indicating the existence of an important system of longitudinal fissures in the rock, through which the oil escapes, and, penetrating the superficial nearly detritus, makes its appearance at the surface.

At Ain Zeff, after three failures to obtain oil by boring, a fourth well encountered the oil sand at a depth of 416 m., in June 1895, and yielded 200 hectolitres of oil per diem, this quantity decreasing, however, to an average of 70 hectolitres at the time of the author's visit in November. The non-success of the other borings is attributed to their having been carried on in the upper strata of marl and gypsum and abandoned before arriving at the layer of oil sand.

At Sidi-Brahim a heading, 5 m. in length, has uncovered a permanent spring of oil and tar, yielding 29 litres per diem. Two wells have also been sunk, one of which had to be abandoned, through an accident, at 212·95 m., but the second well has reached a depth of 228·40 m., and is being sunk deeper. Traces of oil were met with at five different levels, and a vein of gas was struck at 184½ m.

Owing to the fact that the oil in the No. 1 well at Ain Zeff is derived from merely the surface of the oil sand, its composition is regarded as not representing the bulk. The Sidi-Brahim oil and that of the undeveloped sources at Taghria, are expected to yield 15 per cent. of burning oil, 28 per cent. of intermediate oil, 31 per cent. of lubricating oil, and 23 per cent. of paraffin, vaselin, &c.—C. S.

Benzene and Toluene, Purification of. A Method for Purifying, by means of Aluminium Chloride, Hydrocarbons containing Thiophene, its Homologues, and other Impurities. Haller and E. Michel. Bull. Soc. Chim. 15, 1896, 1065—1070.

WHEN preparing benzoylbenzoic acid by the Friedel and Crafts' method, it was observed that a much purer acid was obtained when, in place of using crystallised commercial benzene, the benzene employed was such as had been recovered, i.e., had already been subjected to a treatment by aluminium chloride. The method under discussion is based on this discovery. It is employed on a manufacturing scale at the St. Denis works, and also in several laboratories, including that at the Ecole de Chimie at Mulhouse. The hydrocarbon, rendered as free from water as possible, is

agitated with aluminium chloride, the quantity of which depends upon the amount of impurity in the benzene. The amount of thiophene can be approximately determined by means of the indophenine reaction. When small quantities only are present, isatin and sulphuric acid give a blue coloration, whilst with more of the impurity a dirty brown coloration is produced. For a tolerably pure benzene, 0·5 to 1 per cent. is sufficient, but in certain cases as much as 4—5 per cent. may be required. After agitation, when a reddish viscous product separates at the bottom of the vessel, the hydrocarbon is rectified either directly from the same vessel or after separation. Benzene thus purified, not only does not show the indophenine reaction, but also does not colour sulphuric acid even after several days' contact, and it freezes at 5·4° C. With regard to the yields obtained, 1 kilo. of benzene, purified by sulphuric acid, after purification with 5 grms. of aluminium chloride, gave 980 grms., or a yield of 98 per cent. The results obtained with toluene are inferior as regards yield to those obtained with benzene. Toluene, which contains thiotoluene, gives a violet coloration with sulphuric acid and phenanthraquinone. The experiments were carried out with a sample of toluene boiling at 109·5°—111° C., and giving a dark yellow coloration with sulphuric acid. After heating 2 kilos. of toluene with 2 per cent. of aluminium chloride on a sand bath for an hour, the product, after distillation, ultimately yielded 77·55 per cent. of pure toluene. The toluene thus purified is no longer coloured when shaken with sulphuric acid, and does not give the phenanthraquinone reaction. This process is the subject of the following patents:—Fr. Pat. 240,111 and Ger. Pat. 79,505, 1894.—T. A. L.

PATENT.

Distilling [Tarry Matters], Impts. in Means or Apparatus for; also applicable for Enriching Gases by means of Hydrocarbons. P. Dyckovitz, London. Eng. Pat. 18,877, Oct. 8, 1895.

THE apparatus consists of two or more closed chambers (preferably three), superimposed, each of which is fitted with a heating coil and a capped outlet for drawing off the distillation residues into the vessel next below. When used for carburetting gases, the gas to be enriched is introduced above the surface of the tarry matter employed, and the action may be increased by passing a current of air, or of the gas itself, through the tar by means of perforated pipes provided for that purpose.—C. S.

IV.—COLOURING MATTERS AND DYES.

Triphenylmethane Dyestuffs, The Influence of the Position of the Sulphonic Group on the Shade and Fastness of. T. Sandmeyer. J. Soc. of Dyers and Colourists, 12, [9], 154.

A SERIES of experiments have led the author to conclude that the greenish-blue shade and fastness to alkalis of Patent Blue and other dyestuffs of this class, prepared by condensing *m*-oxybenzaldehyde with alkylated aromatic amines, sulphonating the resulting leuco compounds and then oxidising the same, are due to the presence and position of the sulphonic group, and that the employment of the meta-oxy compounds is not essential, as has been supposed.

By condensing tetramethyldiamidodiphenylcarbinol with metanilic acid, eliminating the amido group of the resulting leuco compound by means of the reactions of Griess, and subsequent oxidation, the author has succeeded in preparing the hitherto unknown orthosulphonic acid of Malachite Green. The result fully justified his conclusion, inasmuch as the resulting dyestuff was fast to alkali, and of a beautiful blue shade.

It is thus shown that triphenylmethane colouring matters can be converted by the introduction of the sulphonic group in the ortho position to the methane carbon, into colouring matters which are bluer in shade and fast to alkali.

The preparation of benzaldehyde orthosulphonic acid is also described.

o-Chlorobenzaldehyde is heated with a neutral solution of sodium sulphite in autoclaves for 10 hours at 190–200° C. The solution of the sulphonic acid thus obtained, is acidulated and boiled, to destroy excess of sulphite. This preparation in combination with ethylbenzidine gives a beautiful green dye, analogous to Acid Green.—I. S.

Meldola's Base (p-Amidobenzene-azo-amido- α -naphthalene).

L. Paul. Zeits. für ang. Chem. 1896, 520–524.

As to the preparation of Meldola's base, the following details are given:—

I. *Preparation of the Nitro-amido Base.*—14 kilos. of *p*-nitraniline are dissolved in 86 kilos. of hydrochloric acid (12° B.) by blowing in steam, the solution being filtered through a small flannel filter into a 2,300-litre vat, provided with an agitator, and containing about 1,000 litres of water, the residue being boiled up with water (2 buckets full) and 10 kilos. of hydrochloric acid. After cooling to 5° C. by adding ice, 6–7 kilos. of sodium nitrite as a 25 per cent. solution are quickly added, and the resulting diazo solution, containing a slight excess of nitrite, is only faintly turbid. In the meantime, 14 kilos. of α -naphthylamine are dissolved in about 500 litres of water and 11–12 kilos. of hydrochloric acid (20° B.), and mixed with another 500 litres of cold water. The solution, when quite cold, is filtered into a 4,000-litre vat fitted with an agitator, into which the diazo solution is also run. The combination is complete in about an hour, when 45–50 kilos. of soda lye (10° B.) are added and the nitro-base is filter-pressed, giving about 230–240 kilos. of cake.

II. The reduction is carried out in a steam-jacketed iron vessel represented in the accompanying figure.

Fig. 1.

It contains about 1,320 litres, and is provided with steam-jacket *e*, discharge pipe *s*, an agitator *r*, manhole *M*, thermometer tube *t*, pressure-gauge *m*, and blow-off valve *x*. About 500 litres of alcohol are put into the vessel and well mixed with the press-cakes from the preceding operation and 60 kilos. of crystallised sodium sulphide. The temperature is then raised by means of the steam jacket to 60° C., and the pressure, which rises to half an atmosphere, is reduced by opening the valve *x*. At 75° C. the steam is shut off, and the temperature rises spontaneously from 78° to 80° C., the pressure being half an atmosphere. The apparatus is kept for about five hours at this temperature, and next day,

when cooled to 30°–35° C., the solution is filtered to remove iron sulphide, and run into a 1,500-litre vat containing 585 litres of water and 100 kilos. of ice. The temperature rises to 10° C., and the volume is 1,200 litres. After two hours' agitation the base is completely precipitated, and, having been filtered off, is twice washed with water. The alcoholic solution is run into a horizontal boiler (see figure 2), and, after

Fig. 2.

previous neutralisation with lime, the alcohol is distilled off. The yield is 15.5 kilos., whilst an experiment on a smaller scale gave 19 kilos. Since the sulphate is insoluble, this salt may be used for quantitative determinations of the base.

III. When 5 kilos. (= 750 grms. dry) of the nitro-amido paste obtained under I. is treated with 15 kilos. of sodium bisulphite (35° B.) and 1.5 litres of water at 80°–90° C. in a lead-lined vessel for 6–7 hours, a sulphonic acid is obtained, which dissolves easily in water and dyes wool and silk in presence of bisulphite and tartar emetic or cotton mordanted with alumina, a sulphur yellow, but it is not suitable for printing. The colouring matters, however, have no technical value, and are only of interest from the fact that they are turned blue on the fibre by alkalis, and orange by acids. The action of alkalis on the nitrosulphonic acid forms a red nitroso sodium sulphonate. This or the yellow sodium nitrosulphonate, on reduction with sodium sulphide at 60°–70° C. and precipitation with hydrochloric acid, when the melt turns violet, yields a monosulphonic acid, which, however, cannot be diazotised, and also appears to be unstable. The same reactions can be carried out with the azo colouring matters obtained from 1,4'-amidonaphthol in place of α -naphthylamine, but the products have no technical interest.

IV. *Preparation of Nyanza Black.*—8 kilos. of diamine base (= 2.9 kilos. solid) are dissolved in so much water at 50°–60° C. and 6 kilos. of hydrochloric acid (12° B.), that the total volume amounts to 210 litres. After filtration and titration of a sample with nitrite, the residue being twice treated with 0.5 kilo. of hydrochloric acid and 25 litres of water, 9 kilos. of hydrochloric acid are added and so much ice that the temperature is reduced to 8°–10° C., the total volume then being 300 litres. This is diazotised (only one amido group reacts) by adding 3.76 kilos. of a 25 per cent. nitrite solution, and the whole, after about 10 minutes, is run into a solution containing 3.29 kilos. of amidonaphthol sulphonic acid G (47 kilos. of a 7 per cent. solution), and 7.4 kilos. of sodium carbonate (equivalent to 5 mols. of hydrochloric acid, 12° B.). After 12 hours' agitation the whole is boiled up, when the colouring matter separates in a granular form. On filter-pressing and drying, 6.3 kilos. of strong colour are obtained, which, after dilution with 66½ per cent. sodium sulphate, is sent into the market as Nyanza black.—T. A. L.

Tartrazine, Action of Diazo Compounds on. R. Grehm and L. Benda. Ber. 29, 2017–2019.

By combining *p*-nitrodiazobenzene with an alkaline solution of Tartrazine, a considerable quantity of nitrogen is disengaged, and, after neutralisation with dilute hydrochloric acid, there results a reddish-brown precipitate, which dissolves in hot water with an orange-yellow colour, and separates in yellow needles. Sodium carbonate colours the aqueous solution red, whilst concentrated caustic soda added to the solid substance colours the latter reddish-brown to violet, and, on warming, a very small quantity is

dissolved with a violet colour; when the solution is diluted the reddish colour is produced, which is obtained directly with sodium carbonate. Wool is dyed orange from an acid bath, the shades being very fast to light. The course of the reaction appears to be represented by the following equation:—

The *p*-diazobenzene sulphonic acid which is split off decomposes at once with evolution of nitrogen. This view is supported by the analytical data and also by the fact that a substance identical with the above is obtained by combining equimolecular proportions of dioxytartaric acid, *p*-nitrophenylhydrazine and *p*-phenylhydrazine sulphonic acid. Some volumetric data are quoted with regard to the amount of nitrogen evolved, which approximates to 2N. It is proposed to investigate other Tartrazines and diazo compounds in the same manner.—T. A. L.

Azonium Compounds from β-Naphthoquinone Sulphonic Acid and Phenyl-o-Phenylene Diamine. F. Kehrman and E. Locher. Ber. 29, 2072—2075.

The condensation of 1,2,4-naphthoquinone sulphonic acid and phenyl-*o*-phenylene diamine yields the two azonium compounds theoretically possible:—

One molecular proportion of the potassium salt of naphthoquinone sulphonic acid is dissolved in just sufficient water at 20° C., acidified with sulphuric acid, and nearly one molecular proportion of phenyl-*o*-phenylene diamine hydrochloride in an aqueous solution is gradually added. A crystalline precipitate separates out, which, after half an hour, is filtered off, washed with water and alcohol, and then heated with acetic acid in the proportion of 50 c.c. to every 2 grms. of precipitate. After cooling, the whole is filtered, when a light yellow crystalline powder of I. remains behind, whilst the filtrate on standing deposits dark brown prisms of II. Both compounds can be purified by crystallisation from 70 per cent. acetic acid. The compound I. forms brownish-yellow crystals, melting at 302°—304° C., tolerably soluble in dilute alcohol and acetic acid, with a yellow colour and a greenish-yellow fluorescence. A trace of aniline added to the alcoholic solution colours it carmine (formation of Phenylrosinduline). The sulphuric acid solution is magenta-coloured. The analytical results point to the substance being constituted as above, but the authors consider it still possible that an inner condensation may have taken place between the sulphonic acid group and the hydroxyl. In the case of compound II. such a condensation has undoubtedly taken place, the substance crystallising from 70 per cent. acetic acid in reddish-brown prisms, which melt above 360° C. The solutions in alcohol or acetic acid are reddish-yellow and non-fluorescent, and whilst I. is almost tasteless, II. has a very sweet taste and dissolves in sulphuric acid with a dirty purple-red coloration. By boiling the alcoholic solution with aniline or dimethylamine, it turns violet-blue and deposits bronzy crystals. The condensation of β naphthoquinone with phenyl-*o*-phenylene diamine has also been carried out, and the compound obtained in the form of its well-crystallised iron double salt. The preparation of this compound is of especial interest, since it is the parent substance of Rosinduline and Isorosinduline, and experiments are in progress to eliminate the amido group from these compounds with a view of proving their azonium structure. In conclusion, reference is made to Kehrman's paper (Annalen, 290, 247 *et seq.*;

this Journal, 1896, 536), again pointing out that Fischer's arguments (Ber. 29, 1870; this Journal, 1896, 646) against the azonium formula are fallacious, and that the author's views still best express the relationship between the Safranine bases and their salts.—T. A. L.

PATENTS.

Salts of Aniline and its Alkyl Derivatives and of all its Homologues, Process for Producing the. A. Welter, Crefeld, Germany. Eng. Pat. 15,836, Aug. 22, 1895.

The process consists essentially in evaporating the aniline base, after neutralisation with an acid, in a vacuum pan, at a comparatively low temperature (60° C.). Important advantages are claimed. In the first place, the whole of the base employed is obtained as anhydrous crystalline salt, this being the case even with the salts of certain bases (alkyl derivatives of aniline, &c.) hitherto known only as syrups. Volatile impurities, such as hydrocarbons, &c., are expelled; and as regards the salts of volatile acids, the excess of acid is driven off, and perfectly neutral preparations obtained. Mixed salts, homogeneous in composition, may be produced straight away, by operating on a mixture of the corresponding bases. Finally, the decompositions and changes incidental to drying at high temperatures (e.g., the transformation of aniline nitrate into nitraniline) are entirely prevented.—H. T. P.

Sulpho Acids of the Naphthalene Series, and of Colouring Matters [Red to Violet] derived therefrom, Impt. in the Manufacture of. H. H. Lake, London. From "Farbwerk Mühlheim," Mühlheim-on-the-Maine, Germany. Eng. Pat. 19,253, Oct. 14, 1895.

The 1,1',3-amidonaphthol sulphonic acid is of no technical value, but on sulphonation it yields 1,1',3,4'-amidonaphthol disulphonic acid, which possesses valuable properties. The constitution of the new acid has been determined on the one hand by boiling it with dilute sulphuric acid at 110° C., when one sulphonic acid group is split off, the original acid being regenerated; whilst if it be fused with caustic alkalis, the amido group is replaced by the hydroxyl group, and a dihydroxynaphthalene disulphonic acid is obtained identical with that of Eng. Pat. 17,141C of 1893 (this Journal, 1894, 878). In order to produce the new acid, 1 kilo. of powdered monosulphonic acid is dissolved in 5 kilos. of concentrated sulphuric acid. The disulphonic acid gradually separates in a crystalline form, and the whole melt is then poured into ice water, boiled up, and the disulphonic acid is salted out. The new acid is to be employed as a dyestuff component in the usual manner, and if two molecular proportions are combined, for example, with one molecular proportion of tetrazoditoly, in a concentrated alkaline solution, the intermediate compound first formed is gradually transformed into the tetrazo dyestuff, which gives blue shades on unmordanted cotton. Diazotised *p*-nitraniline sulphonic acid gives, on combination in an alkaline solution, a colouring matter dyeing deep red shades, whilst *p*-nitraniline gives a reddish-violet, and aniline disulphonic acid (by sulphonating metaniline acid) gives a scarlet. A green for unmordanted cotton is obtained by first combining diazotised sulphanilic acid with one molecular proportion of the new acid in a slightly acid aqueous solution. The mono-azo dyestuff thus produced is dissolved in an excess of sodium carbonate and mixed with one molecular proportion of the intermediate compound from tetrazoditoly and salicylic acid. After the combination is complete, the dyestuff is isolated in the usual manner.

—T. A. L.

Azo Dyestuffs [Yellow to Red] from New m-Nitraniline Sulphonic Acid, Manufacture of. O. Imray, London. From "The Farbwerke vormals Meister, Lucius, and Brüning," Hoechst a. M., Germany. Eng. Pat. 20,313, Oct. 28, 1895.

The specification describes the preparation of azo colouring matters from the *m*-nitraniline sulphonic acid of Eng. Pat. 14,382 of 1895 (this Journal, 1896, 539). The following is a typical example of the method employed:—2.18 kilos. of *m*-nitraniline sulphonic acid mixed with 1.2 kilos. of

hydrochloric acid and sufficient water to form a thin paste are diazotised at the ordinary temperature by adding a solution of 0.69 kilo. of sodium nitrite. The diazo compound formed is run into 2.39 kilos. of amidonaphthol sulphonic acid G, stirred up with water to form a thin paste. The liquid turns an intense red, and, after stirring some time, is neutralised with soda and the dye-stuff is salted out. It forms a brown powder, easily soluble in water to a red solution, which dyes wool a bluish-red in even shades very fast to alkalis. The range of colours, according to the dye-stuff component employed, varies from yellow to red.

—T. A. L.

Colouring Matters [Violet or Blue Tetrazo]. *Impts. in the Manufacture of.* H. H. Lake, London. From K. Ochler, Offenbach-on-the-Maine, Germany. Eng. Pat. 20,530, Oct. 30, 1895.

THESE colouring matters are obtained from *o*- and *p*-hydroxyquinolines and their homologues by employing them for combination with the intermediate compounds produced for instance, by combining equimolecular proportions of benzidine and 1.1'.3.3'-amidonaphthol disulphonic acid, of which the following may be taken as an example as to the quantities employed:—10.6 kilos. of tolidine are converted into the tetrazo derivative and combined with 17 kilos. of the acid sodium salt of 1.1'.3.3'-amidonaphthol disulphonic acid. The intermediate compound thus obtained is poured into an alkaline solution of 7.5 kilos. of *o*-hydroxyquinoline. After standing some hours, the mixture is heated and the colouring matter is salted out, filter-pressed, and dried. The dyestuff has a greyish-green metallic lustre and dissolves in water to a violet-brown solution which dyes cotton a dark violet shade. In place of tolidine, benzidine or dianisidine may be employed, the shades obtained varying from violet to red li-b-blue. They are said to be distinguished by their clearness and fastness to light.—T. A. L.

Nitrotoluene, Impts. [Separation of Isomerides] in the Treatment of Technical. A. G. Green, Heaton Moor, and H. Benfey, Manchester. Eng. Pat. 20,941, Nov. 5, 1895.

THE object of this invention is the production from technical nitrotoluene (which contains the ortho- and para-isomers) of *p*-toluidine and *o*-nitrotoluene. This is effected by fractional reduction with any suitable soluble sulphide, advantage being taken of the fact that *p*-nitrotoluene is more readily reducible than the ortho-compound. A special feature is the use of Leblanc alkali waste as reducing agent.—H. T. P.

Trisazo Colouring Matters, Manufacture of New. O. Imray, London. From "The Farbwerke vormals Meister, Lucius, and Brüning," Hoechst-am-Main, Germany. Eng. Pat. 21,342, Nov. 11, 1895.

THE dihydroxynaphthalene sulphonic acid S of Ger. Pat. 67,829 will combine with two molecular proportions either of the same or of different diazo compounds. If the second diazo compound in the above combination be replaced by a molecular proportion of a tetrazo compound, a derivative is obtained which will further combine with amines, phenols, naphthols, or their sulphonic or carboxylic acids. The colouring matters thus obtained dye wool and cotton in shades fast to light and soap. Moreover, those combinations which contain a diazotisable group may be further diazotised on the fibre, and when developed give very fast shades of violet to deep black. One molecular proportion of dihydroxynaphthalene sodium sulphonate S and three molecular proportions of sodium carbonate are dissolved in water to a 10—15 per cent. solution, mixed with one molecular proportion of diazonaphthionic acid, and stirred for six hours. About four molecular proportions of sodium carbonate are then added, and afterwards one molecular proportion of tetrazodiphenyl at 0° C. After standing 1—2 hours, the intermediate compound is poured, with constant agitation, into a solution containing one molecular proportion of amidonaphthol disulphonic acid II and 2—3 molecular proportions of sodium carbonate, in a small quantity of water. The formation of the colouring matter is complete in about 12 hours, when it is separated and purified in the

usual manner. The operation can also be carried out in such a way that equimolecular proportions of tetrazodiphenyl and amidonaphthol disulphonic acid II are combined to form an intermediate compound, which is then combined with the mono-azo colouring matter from naphthionic acid and dihydroxynaphthalene sulphonic acid S. Another modification consists in combining one molecular proportion of tetrazodiphenyl with one molecular proportion of dihydroxynaphthalene sulphonic acid S and one molecular proportion of amidonaphthol disulphonic acid II in an alkaline solution. The product thus obtained is then further treated in an alkaline solution with one molecular proportion of diazonaphthionic acid. A large number of instances of the various combinations are quoted, but no further details are given as to the shades of the colours produced.—T. A. L.

Sulpho Acids of the Naphthalene Series and of Colouring Matters derived therefrom, Impts. in the Manufacture of. H. H. Lake, London. From Farbwerk Mühlheim, Mühlheim a. M., Germany. Eng. Pat. 21,919, Nov. 18, 1895.

THE amidonaphthol disulphonic acid B (Eng. Pat. 19,253 of 1895; see page 708), produced by sulphonating 1.1'.3-amidonaphthol sulphonic acid (obtained by fusing 1.3.1'-naphthylamine disulphonic acid with alkalis), yields, by the action of caustic alkalis, 1.1'.4.3'-dihydroxynaphthalene disulphonic acid identical with that described in Eng. Pat. 17,141 of 1895 (this Journal, 1894, 878). The azo colouring matters derived from the acid B can also be transformed into the corresponding dihydroxy dyestuffs either by the action of alkalis or mineral acids. For the production of the new acid, 5 kilos. of the disulphonic acid B, dissolved in 10 kilos. of caustic soda lye (40 B.) and 40 litres of water, are heated for 10 hours in an autoclave to 220°—240° C. The reaction is complete when a sample diluted with water, made acid with hydrochloric acid, and treated with sodium nitrite, yields a yellow solution which does not turn violet when made alkaline with sodium carbonate. The whole solution is then acidulated with hydrochloric acid and the new acid precipitated with salt. As an example of the production of a dihydroxy colouring matter, 1 kilo. of the dyestuff obtained from diazosulphanilic acid and acid B in a slightly acid solution, is added to 8 kilos. of caustic soda lye (40 B.), and the solution is boiled until ammonia is no longer evolved. The melt is then diluted and acidulated with hydrochloric acid, when the dihydroxy dye-stuff separates in a crystalline condition and dyes wool bright red shades. By substituting other aromatic amido acids for the sulphanilic acid, shades varying from yellowish-red to claret can be obtained. The conversion by means of a mineral acid is carried out by boiling 3 kilos. of the dye-stuff (from *p*-nitrodiazobenzene and acid B in a slightly acid solution) with 10 kilos. of concentrated hydrochloric acid and 100 litres of water under an inverted condenser until a bluish-red solution is obtained and a dyeing on wool shows no further increase in purity of shade. The dihydroxy dye-stuff crystallises out on cooling, and dyes wool deep red shades.—T. A. L.

Disazo, and Polyazo Colouring Matters with Phenylene and Tolylen-aramic Acid, Manufacture of. O. Imray, London. From P. Remy, Farbwerk Friedrichsfeld, Mannheim, Germany. Eng. Pat. 22,114, Nov. 20, 1895.

THE specification refers to the employment of phenylene and tolylene oxamic acids as dyestuff components, the combinations being carried out in the usual manner. Thus a solution of 26.4 kilos. of benzidine sulphonic acid in 500 litres of water, with the necessary quantity of alkali, is converted into the tetrazo compound with 14 kilos. of sodium nitrite and added to 38.8 kilos. of tolylene oxamic acid in 1,000 litres of water containing 50 kilos. of sodium carbonate. After salting out the colouring matter, it is filter-pressed, washed, and dried. It dyes unmoderated cotton brown. In place of employing two molecular proportions of the oxamic acid, the second one may be replaced by some other dyestuff component. For instance, the dyestuff having the formula—

and obtained by combining tetrazodiphenyl with sodium naphthionate and phenylene oxamic acid, dyes unmordanted cotton scarlet. All these colouring matters may be further diazotised and combined on the fibre, giving shades fast to acids, alkalis, washing, and light. The conversion into polyazo colouring matters can also take place outside the fibre in the usual manner, giving as a rule dark shades.

By the employment of *m*-nitrobenzidine and the corresponding tolidine derivative in the above combinations, valuable wool dyestuffs are obtained, fast to washing, felling, acids, alkalis, and sulphur. In all the combinations the oxalyl group can be split off by boiling the dyestuff with dilute hydrochloric acid (about 5° B.). No material difference appears to be made in the shade by this treatment, but the derivatives obtained are capable of further diazotisation and combination. The following example illustrates this method:—A solution containing 40 kilos. of the hydrolysed product, obtained from equimolecular proportions of dionisidine, 1,4-naphthol sulphonic acid, tolylene oxamic acid, and *m*-tolylene diamine, in 1,600 litres of water, is diazotised with 8 kilos. of nitrite and 32 kilos. of hydrochloric acid (20° B.), and after half an hour is stirred into 600 litres of water containing 20 kilos. of R salt and 16 kilos. of calcined sodium carbonate. The colouring matter is salted out, and dyes unmordanted cotton blue. In the specification, tables are given of the various combinations which can be effected and the shades produced.

—T. A. L.

Colouring Matters [Reddish-Brown to Bluish-Violet]. Process for the Manufacture of Intermediate Compounds containing Two Diazo Groups and suitable for the Production of. M. Lange, Amsterdam, Holland. Eng. Pat. 17,293, Aug. 5, 1896.

By reacting with one molecular proportion of a tetrazo compound on one molecular proportion of a diazotised amidonaphthol or its sulphonic acid in a neutral or alkaline solution, there result intermediate compounds which, on combination with aromatic amines, phenols, and amidonaphthols, yield colouring matters dyeing from reddish-brown to bluish-violet shades. The formation of one of these intermediate compounds having the formula—

is obtained as follows:—18.4 kilos. of benzidine are converted into the tetrazo compound in an aqueous solution with 50 kilos. of hydrochloric acid and 13.8 kilos. of nitrite. The diazo compound from 23.9 kilos. of amidonaphthol sulphonic acid G is also prepared with 25 kilos. of hydrochloric acid, and the two diazo derivatives are mixed, a solution of soda being then added until the whole is strongly alkaline. The intermediate compound separates out as a blue crystalline precipitate, and is nearly insoluble in water.

—T. A. L.

VI.—DYEING, CALICO PRINTING, PAPER-STAINING, AND BLEACHING.

Jute. Bleaching of. Grothie. Papier Zeit. 76, 1896, 2453.

The author says many materials can be bleached perfectly white if previously treated with a solution of silicate of soda ("Water-glass"), which cannot be done if the material has been simply boiled with soda. If jute be soaked and agitated for 15–20 minutes in a solution of 6–8 kilos. of water-glass in 10 litres of water at 85°–100°C., and then be washed in water, first warm and then cold, the material may be bleached a good white with a solution of bleaching powder.—S. P. E.

Chromium Fluoride for Wool-chroming. Textile Colourist, 18, [212], 230. (See also this Journal, 1888, 433; 1889, 982; 1890, 60, 732; 1891, 763; 1892, 365.)

Chromium fluoride is steadily displacing potassium bichromate, says the author, for mordanting wool. With chromium fluoride the green colour of the wool is seen from the beginning, and the wool is not oxidised; whereas

with bichromate this result can only be obtained after protracted boiling, the wool fibre being at the same time oxidised. Wool mordanted with chromium fluoride behaves generally with the alizarins like that mordanted with potassium bichromate, and in some cases, particularly with Alizarin Cyanines and Anthracene Blue, gives fuller shades with a finer greenish tone.

A special advantage of chromium fluoride is that it can be applied as a mordant for "topping" the lightest shades of indigo-dyed bottoms, since it has no oxidising action on the Indigo.—I. S.

Aniline Black on Wool with Ammonium Persulphate. T. Skawinski. Färber Zeit. 1896, 7, [22], 345.

A good full black, which rubs off but very little, may be produced on wool by the aid of ammonium persulphate ($\text{NH}_4)_2\text{S}_2\text{O}_8$. The wool (100 parts) is worked for 1½ hours in a cold solution of ammonium persulphate (5–10 parts) in water (4,000 parts). After removing surplus liquor, and without drying, the goods are padded in a solution of 120 grms. of aniline salt, 45 grms. of sodium chlorate, and 80 grms. of potassium ferrocyanide per litre, dried, steamed for ½ hour without pressure, washed, and soaped. For printing on wool the process has not so far given satisfactory results.—I. S.

Aniline Black, White and Coloured Resists on. L. Bloch and Ch. Schwartz. Bull. Soc. Ind. de Mulhouse, 1896, July, 301–303.

ALUMINATE of soda resists Aniline Black very well, and if care be taken when removing the thickening after the passage through the Mather-Platt apparatus, sufficient alumina remains fixed on the cloth to dye those parts with alizarins: red, yellow, fancy shades, and other colours. In this way white, and single-colour or two-colour effects on black grounds may be produced. The process is as follows:—

Pad the goods with aniline solution, print on a white resist consisting of sodium citrate and acetate, and then aluminate of soda. Pass through the Mather-Platt apparatus, remove thickening, dye at a low temperature (alizarins being applied in the usual manner), wash, dry, oil, steam, and soap.

The authors have obtained similar effects with albumin colours by using as a resist stannous sulphocyanide, which resists Aniline Black very well. But the albumin coagulates superficially, and the colours give way easily during soaping. Good results may be obtained, however, by using, along with this resist, certain of the basic colouring matters which resist the action of stannous sulphocyanide during steaming, such as Rhodamine 6 G, Methyl Violet, Victoria Blue, Malachite Green, &c. For the fixation of the colouring matter, a suitable antimony salt and tannin are added to the printing composition at the same time.

A white resist is made by dissolving 2.1 kilos. of barium sulphocyanide in 3.7 litres of warm water, to which are added 1.75 kilos. of tin salt and 4 kilos. of British gum. For coloured resists, 2.1 kilos. of barium sulphocyanide are dissolved in 1 litre of warm water, and to the solution 1.75 kilos. of tin salts are added, and the whole is stirred into a paste consisting of 2.5 litres of colour solution (50 grms. of a basic colouring matter in 0.5 litre of water and 0.5 litre of acetic acid) and 4 kilos. of British gum. When cold, 0.5 kilo. of tannin and 0.3 litre of acetic acid of 6° B. are added, and lastly 0.25 litre of antimony solution, made by dissolving 140 grms. of tartar emetic in 1 litre of calcium chloride solution of 8° B.—I. S.

Aniline Black, White and Coloured Resists on. (Note on preceding Article.) A. Romann. Bull. Soc. Ind. Mulhouse, 1896, July, 304–305.

The use of sodium citrate and acetate as a resist for Aniline Black, and the simultaneous employment of sodium aluminate to serve as a mordant for subsequent dyeing, have long been known. The process is of easy application, but has been abandoned on account of its inutility. The same effects may be produced by using albumin colours along with the resists in common use.

The author has repeated the process of Bloch and Schwartz, who employed stannous sulphocyanide, obtained from tin salt and a soluble sulphocyanide, as a white resist, and can confirm their results. Since the opening of their sealed note in which this process was made public, Bloch and Schwartz have published a modification of their formula, consisting of an addition of zinc sulphate and raw starch to their former mixture. The zinc sulphate reserves the albumin colours much better, but, on account of its acidity, it does not resist the aniline black so well, whilst the starch merely increases the viscosity of the mixture, necessitating a further increase of the proportion of sulphocyanide in order to obtain a good white. The author has shown by trials that the resists in common use—sodium carbonate, acetate, or citrate—produce a better white than stannous sulphocyanide.

The new formula of Bloch and Schwartz is stated to be as follows:—3.5 kilos. of tin salt and 2.8 of potassium sulphocyanide are dissolved in 7.5 litres of water, and thickened with 8 kilos. of British gum. To this mixture are added 1 kilo. of starch, 0.5 litre of water, and 2.5 kilos. of zinc sulphate.—I. S.

Indigo Substitutes for Cotton Yarns, Basic Dyestuffs as.
S. Freund. *Färber Zeit.* 7, [24], 378.

No substitute has yet been discovered which could replace Indigo as perfectly as, for instance, Alizarin does Madder in Turkey-red dyeing. Some of the basic colouring matters, however, so closely approximate Indigo in shade, fastness to light and soaping, that they are successfully applied as substitutes for that dyestuff.

Indoim Blue B B and Naphthindone B B appear to be the most suitable for this purpose. The properties of both are similar, the only difference being that the former is sold as a paste and the latter as a dry powder. The dyes with these colouring matters closely resemble those of Indigo, and all the usual shades of the latter can be produced; with Naphthindone even the copper shade of dark Indigo appears.

As a special advantage in the case of these two colouring matters as compared with other basic dyestuffs, the author mentions their great tinctorial powers, $1\frac{1}{2}$ to $2\frac{1}{2}$ per cent. giving full blues, whilst 3 per cent. is sufficient, it is stated, for the darkest shades. Great care is necessary, however, in order to obtain even dyeing. Calcareous water should be corrected by the addition of acetic acid, alum, or aluminium sulphate. Sumach is to be preferred to tannic acid in the mordanting, as it gives fuller shades.

The following proportions of sumach, antimony, and dyestuff are recommended:—

Dyestuff.	Sumach.	Double Salt of Antimony.
Per Cent.	Per Cent.	Per Cent.
1	7	$\frac{1}{2}$
$1\frac{1}{2}$	10	1
2	15	$1\frac{1}{2}$
$2\frac{1}{2}$	19	2

The sumach bath should be acidulated by adding to the same $\frac{1}{2}$ litre of acetic acid (30 per cent.) for every 50 kilos. of yarn, and the dye-bath by the addition of 3 per cent. of alum or 2 per cent. of aluminium sulphate. The colour is dissolved with the addition of $\frac{1}{2}$ litre of 30 per cent. acetic acid and is then added to the bath. Enter the mordanted goods at 50° C., work 20 minutes, lift, raise the temperature to 75° C., and work another 20 minutes. If the bath is not exhausted, add to it a decoction of 1 to 2 lb. of sumach, and work the goods for another 15 minutes. This second sumaching at the same time assists in the better fixation of the colour.

—I. S.

Dyeing Apparatus, Improved, for Yarns and Cloth. U.S.
Consular Reports, Sept. 1896, 52, [192], 152—155.

The drum A rests on suitable framework, and is connected by steam pipes with the hollow and perforated cylinder D.

Into this cylinder from 1,500 to 2,000 hollow and perforated spikes H may be screwed, on which latter the cops J are placed. By means of the thumb-screws E the cylinders can be quickly inserted into or removed from the arms B. The

joint F admits both of raising and dipping the cops carrier from or into the movable vat. The drum A is provided with a vacuum chamber and a compressed air cylinder, which are connected with a reversible air pump by pipes H, and are controlled by the valve handles G. A pipe from A leads to the tank containing the reserve dyes.

The dyeing is performed in the following manner:—A vacuum is created, whereby the liquor is sucked through the cops, the perforated spikes, and the cylinder into the drum A, where it is brought up to strength by a concentrated solution drawn in at the same moment and by the same force from a reserve tank. Then steam is admitted, and the liquor contained in the drum A is pressed outward. All operations of dyeing, washing, steaming, &c., both on cops or piece-goods, may be performed with this apparatus.—I. S.

Silk Warps, Printing of. Report of the Zürich Silk-Weaving School. *Textile Colorist* (U.S.), 18, [213], 267.

BEFORE the warps are delivered to the printer, a few picks are shot through at distances of 35—40 mm., forming a kind of woven portion, 7—15 mm. in length. It is advisable to weave at the beginning about 20 cm. of the stuff, and to shoot in several picks on either side of the lease-cord, to keep it in position.

For printing, the warp is stretched upon a table about 20 m. long, covered with cloth, and the colours are applied by means of blocks as is usual in hand-printing. When the whole length upon the table has been printed, 20 m. more of the warp are pulled on to it, whilst the printed part is placed upon a higher platform. When the entire length has been printed, the warp is hung up in a box, and is there exposed for 40—50 minutes to the action of very hot, dry steam to fix the colours. After steaming the warp is put into a bag, and agitated or "whipped" in water by two men, to remove adhering impurities; it is then "whizzed" in a hydro-extractor, and hung up in loops until dry. The warp is then again beamed, and whilst running on to the beam, is exposed to the action of the brush, whereby the threads are again neatly placed side by side. Designs may also be printed in this manner on dark dyed warps by discharge.—I. S.

Silk Pongees and Foulards, Printing of. Report of the Zürich Silk Weaving School. Textile Colorist (U.S.), 18, [213], 267.

A PECULIAR kind of block printing and treatment is applied to silk pongees and foulards, which are woven of raw silk. The dots and small designs on these goods, which are mostly of a light colour on dark ground, are produced as follows:—The material is first dyed a light colour for the design, and is then printed over with a cement-like mass (mastique). The printed parts are sprinkled over with finely-powdered pipe-clay to prevent these parts from sticking together, and the cloth is hung up to dry. The silk is then dyed a dark shade for the ground. The cement is subsequently removed with benzene, leaving a light design on a dark ground.—I. S.

PATENT.

Producing Print Patterns in Colours on Cotton Fabrics by the Aid of Safranine-Azo Dyestuffs. R. Michel, Vienna, Austria. Eng. Pat. 19,444, Oct. 16, 1895.

IN order to obtain red patterns on a blue ground, the cotton fabric, after having been dyed with a colouring matter derived from diazosafranine and a dyestuff component, is printed with a tin-acetate discharge, steamed, and washed, when the desired effect is obtained. For instance, the dyestuff produced from diazosafranine and β -naphthol in acetic acid solution, and known as naphthindone, is dyed on cotton cloth mordanted with tannin and tartar emetic. A discharge is then printed on, consisting of 2 litres of acetate of tin (42° Tw.), 200 grms. of wheat starch, and 150 grms. of white dextrin. The goods are then steamed and washed, when a bluish-red design appears on a dark blue ground. The shade of the former can be modified by printing with the discharge, non-reducible dyestuffs, such as Thioflavine T, or Eosine, &c. The process may also be reversed, the discharge being first printed as a resist. Moreover, the employment of a mordant is not in all cases necessary, since certain of the safranine-azo colouring matters dye unmordanted cotton.

—T. A. L.

VII.—ACIDS, ALKALIS, AND SALTS.

Salt in the Isle of Man. W. B. Dawkins. Proc. British Association, Chemical Section, 1896.

THE author states that salt was found from a boring made at the Point of Ayre. The salt set in at 500 ft. below the surface, and the total thickness of the rock salt was 33 ft. 6 ins., the two thickest beds being respectively 20 ft. and 9 ft. 6 ins. Besides these, a brine run, 2 ft. 6 ins. in depth, occurred at a depth of 615 ft. 5 ins. from the surface. The depth of the salt-field remained unproved.—A. S.

Tartaric Acid, The Manufacture of. V. Hölbling. Mitt. k.k. Tech. Gew. Museums in Wien, 1896, 6, 133—141.

THE source of the tartaric acid of commerce is the juice of the wine grape, in which it occurs in the form of acid potassium tartrate and calcium tartrate.

During and after the fermentation of the grape juice, part of the tartrates is deposited on the walls of the tun as argol, and part is contained in the sediment known as lees. The lees are used for the manufacture of tartaric acid, either in the moist condition or after being dried. The moist, pasty lees are removed from the tuns into sacks, and pressed. They then contain varying amounts of acid potassium tartrate and calcium tartrate, with some alcohol and higher esters. They are mixed with water and distilled, the distillate yielding the so-called Lager brandy and wine oil or Cognac oil. The residue, which is used for the manufacture of tartaric acid, contains from 1 to 8 per cent. of that acid. Lees containing a higher percentage of tartaric acid, which only occurs after the first stage of the fermentation, are well pressed and dried, usually by the heat of the sun, and sold as dried wine lees.

To obtain the tartaric acid from the crude materials (argol and wine lees), the only method suitable for technical purposes is the precipitation of the acid potassium tartrate

as calcium tartrate, and subsequent preparation of the tartaric acid from the latter. The methods of obtaining the calcium tartrate vary according to the nature of the crude material. A suitable method of obtaining it from argol is to mix the argol, preferably in the form of powder, with water, and boil, after the addition of some hydrochloric acid, the best proportions being 1—5 eb. m. of water with 110—120 kilos. of crude hydrochloric acid (20°—22° B.) to about 500 kilos. of argol. Milk of lime is then added to the boiling mass until this is nearly neutral, when calcium tartrate is precipitated and neutral potassium tartrate and calcium chloride left in solution. The neutral potassium tartrate is decomposed either by boiling with a sufficient quantity of calcium sulphate or by adding calcium chloride solution, an excess of the precipitant being avoided in either case. The small amount of acid potassium tartrate purposely left in the liquid, when treating the latter with milk of lime, is decomposed with pure precipitated calcium carbonate. The object of not adding the milk of lime to the neutral point or in excess is to avoid the precipitation of iron oxide and alumina. The solution must still remain perceptibly acid after the addition of the calcium carbonate. When cooled to about 40° C., the liquid is filtered with the aid of a suction pump, and the residue washed with water. The dark brown filtrate was formerly treated to recover the calcium chloride and potassium sulphate, but owing to the expense of the process of recovery and purification it is now a waste product.

In the oldest methods of obtaining calcium tartrate from wine lees the latter were boiled with water and hydrochloric acid, the clear solution removed, and the residue treated with more water. As the extraction was very incomplete, these methods have not been employed for the last 30 years. When filtration of the lees was first attempted it was found that the pores of the filter became clogged, and that even under a pressure of 4 or 5 atmospheres no liquid would pass through. This difficulty was overcome by the process of Dietrich and Schnitzer, in which the albuminoid substances are coagulated by heating for about six hours under a pressure of 4 or 5 atmospheres. This method has been in general use for about 30 years. Wet lees, when thus treated, can be readily filtered. Dried lees are crushed, stirred in a tank with water, and heated by steam for some time, until air is completely expelled, before being heated in the pressure boiler. According to the author's experience, preliminary boiling for more than half an hour is superfluous.

Dietrich and Schnitzer's pressure boiler consists of a tightly covered wrought-iron cylinder, with a manhole and charging opening in the cover, through which passes a copper steam-tube with a worm at the bottom, and having small openings at the top of the bend, so that the steam is regularly distributed throughout the entire mass. There is also a tube of copper, through which the lees are forced when the heating is finished. The dimensions of an average-sized cylinder, holding about 1,500 kilos. of lees, are 4 m. in length and about 1.4 m. in diameter. The tubes, which are of copper, and the interior of the boiler, require constant inspection to avoid the danger of an explosion, and every six months the boiler is subjected to a pressure test $1\frac{1}{2}$ times in excess of the maximum normal pressure, since the iron is rapidly corroded. To avoid this danger, and to obviate the drawback of having a considerable amount of iron taken up, which is troublesome in the further stages of the manufacture, experiments have been made to find a substitute for iron as the material for the boiler. Copper is undoubtedly the most suitable metal, but its high price, and the fact that it is not absolutely unattacked, have stood in the way of its adoption. Lining the interior of the cylinder with lead is useless, since the metal is rapidly attacked by the sulphuretted hydrogen liberated from the heated albuminoid matters, and rapidly peels off. The most effective means of protecting the iron is to line the boiler with cement. The most suitable dimensions for a boiler intended to be thus lined are 2 m. in diameter and 2 m. in height.

During the process of heating the lees, the steam passing from the apparatus carries with it volatile empyrenematic products derived from the decomposed albuminoids.

These have a very offensive odour, and should be conveyed into a factory chimney of sufficient height, so that the evil-smelling vapours are drawn up and decomposed by the furnace gases.

When the heating is finished, the steam-outlet pipe is opened and the pressure allowed to fall from 1 to $\frac{1}{2}$ atmosphere, this pressure being required to force the lees from the boiler into a tank, which may be suitably constructed of wood. Here they are mixed with water, which has previously been put into the tank, and the requisite quantity of crude hydrochloric acid (21° – 22° B.). Experience has shown that for every 100 parts by weight of argol in the lees, 100 parts of the acid are required. Too little acid causes deposition of argol in the cloths of the filter-press, whilst too much destroys the cloths, and more lime is required to neutralise the filtrate. If the conditions are right, the filtered liquid should have a specific gravity of about 6° B.

The acidified lees are pressed and washed, the washings being used instead of pure water for mixing with the next charge of lees from the pressure boiler. The tartaric acid in the filtrate is precipitated with lime and calcium carbonate, and the remainder of the process is the same as in the case of argol, with the exception that there is no necessity to add calcium chloride or calcium sulphate.

The calcium tartrate obtained from wine lees is of a clear grey colour, and considerably purer than the dark grey or dark brown product from argol.—C. A. M.

Chlorine, History of the Manufacture of. Ludwig Mond. (President's Address, Chemical Section), Brit. Assoc. Meeting, 1896.

In endeavouring to fix upon a suitable theme for the address I knew to-day would be expected from me, I have felt that I ought to give due consideration to the interests which tie this magnificent city of Liverpool, whose hospitality we enjoy this week, to Section B. of the British Association.

I have therefore chosen to give a brief history of the manufacture of chlorine, with the progress of which this city and its neighbourhood have been very conspicuously and very honourably connected, not only as regards quantity—I believe this neighbourhood produces to-day nearly as much chlorine as the rest of this world together—but more particularly by having originated, worked out, and carried into practice several of the most important improvements ever introduced into this manufacture. I was confirmed in my choice by the fact that this manufacture has been influenced and perfected in an extraordinary degree by the rapid assimilation and application of the results of purely scientific investigations and of new scientific theories, and offers a very remarkable example of the incalculable value to our commercial interests of the progress of pure science.

The early history of chlorine is particularly interesting, as it played a most important rôle in the development of chemical theories. There can be no doubt that the Arabian alchemist Geber, who lived 1,100 years ago, must have known that "Aqua Regia," which he prepared by distilling a mixture of salt, nitre, and vitriol, gave off on heating very corrosive, evil-smelling, greenish-yellow fumes, and all his followers throughout 1,000 years must have been more or less molested by these fumes whenever they used "Aqua Regia," the one solvent of the gold they attempted so persistently to produce.

But it was not until 1774 that the great Swedish chemist Scheele succeeded in establishing the character of these fumes. He discovered that on heating manganese with muriatic acid he obtained fumes very similar to those given off by "Aqua Regia," and found that these fumes constituted a permanent gas of yellowish-green colour, very pungent odour, very corrosive, very irritating to the respiratory organs, and which had the power of destroying organic colouring matters.

According to the views prevalent at the time, Scheele considered that the manganese had removed phlogiston from the muriatic acid, and he consequently called the gas dephlogisticated muriatic acid.

When during the next decade Lavoisier successfully attacked, and after a memorable struggle completely upset

the phlogiston theory and laid the foundations of our modern chemistry, Berthollet, the eminent "father" of physical chemistry—the science of to-day—endeavoured to determine the place of Scheele's gas in the new theory. Lavoisier was of opinion that all acids, including muriatic acid, contain oxygen. Berthollet found that a solution of Scheele's gas in water, when exposed to the sunlight, gives off oxygen and leaves behind muriatic acid. He considered this as proof that this gas consists of muriatic acid and oxygen, and called it oxygenated muriatic acid.

In the year 1785 Berthollet conceived the idea of utilising the colour-destroying powers of this gas for bleaching purposes. He prepared the gas by heating a mixture of salt, manganese, and vitriol. He used a solution of the gas in water for bleaching, and subsequently discovered that the product obtained by absorbing the gas in a solution of caustic potash possessed great advantages in practice.

This solution was prepared as early as 1789, at the chemical works on the Quai de Javelle, in Paris, and is still made and used there under the name of "Eau de Javelle."

James Watt, whose great mind was not entirely taken up with that greatest of all inventions—his steam-engine—by which he has benefited the human race more than any other man, but who also did excellent work in chemistry—became acquainted in Paris with Berthollet's process, and brought it to Scotland. Here it was taken up with that energy characteristic of the Scotch, and a great stride forward was made when, in 1798, Charles Tennant, the founder of the great firm, which has only recently lapsed into the United Alkali Company, began to use milk of lime in place of the more costly caustic potash, in making a bleaching liquid; and a still greater advance was made when, in the following year, Tennant proposed to absorb the chlorine by hydrate of lime, and thus to produce a dry substance, since known under the name of bleaching powder, which allowed the bleaching powers of chlorine to be transported to any distance.

In order to give you a conception of the theoretical ideas prevalent at this time, I will read to you a passage from an interesting treatise on the art of bleaching published in 1799 by Higgings. In his chapter "On bleaching with the oxygenated muriatic acid, and on the methods of preparing it," he explains the theory of the process as follows:—

"Manganese is an oxyd, a metal saturated with oxygen gas. Common salt is composed of muriatic acid and an alkaline salt called soda, the same which barilla affords. Manganese has greater affinity to sulphuric acid than to its oxygen, and the soda of the salt greater affinity to sulphuric acid than to the muriatic acid gas; hence it necessarily follows that these two gases (or rather their gravitating matter) must be liberated from their former union in immediate contact with each other; and although they have but a weak affinity to one another, they unite in their nascent state, that is to say, before they individually unite to caloric, and separately assume the gaseous state; for oxygen gas and muriatic acid gas already formed will not unite when mixed, in consequence principally of the distance at which their respective atmospheres of caloric keep their gravitating particles asunder. The compound resulting from these two gases still retains the property of assuming the gaseous state, and is the oxygenated muriatic gas."

Interesting as these views may appear, considering the time they were published, you will notice that the rôle played by the manganese in the process and the chemical nature of this substance were not at all understood. The law of multiple proportions had not yet been propounded by John Dalton, and the researches of Berzelius on the oxides of manganese were only published 13 years later, in 1812. The green gas we are considering was still looked upon as muriatic acid, to which oxygen had been added, in contradistinction to Scheele's view, who considered it as muriatic acid, from which something, viz., phlogiston, had been abstracted.

It was Humphry Davy who had, by a series of brilliant investigations carried out in the Laboratory of the Royal Institution between 1808 and 1810, accumulated fact upon fact to prove that the gas hitherto called oxygenated

muriatic acid did not contain oxygen. He announced in an historic paper, which he read before the Royal Society on July 12, 1810, his conclusion that this gas was an elementary body, which in muriatic acid was combined with hydrogen, and for which he proposed the name "chlorine," derived from the Greek *χλωρος*, signifying "green," the colour by which the gas is distinguished.

The numerous communications which Humphry Davy made to the Royal Society on this subject form one of the brightest and most interesting chapters in the history of chemistry. They have recently been reprinted by the Alembic Society, and I cannot too highly recommend their study to the young students of our science.

Those who have followed the history of chemistry I need not remind how hotly and persistently Davy's views were combated by a number of the most eminent chemists of his time, led by Berzelius himself; how long the chlorine controversy divided the chemical world; how triumphantly Davy emerged from it; how completely his views were recognised; and how very instrumental they have been in advancing theoretical chemistry.

The hope, however, which Davy expressed in that same historic paper, "that these new views would perhaps facilitate one of the greatest problems in economical chemistry, the decomposition of the muriates of soda and potash," was not to be realised so soon. Although it had changed its name, chlorine was still for many years manufactured by heating a mixture of salt, manganese, and sulphuric acid in leaden stills, as before.

This process leaves a residue consisting of sulphate of soda and sulphate of manganese, and for some time attempts were made to recover the sulphate of soda from these residues, and to use it for the manufacture of carbonate of soda by the Le Blanc process. On the other hand, the Le Blanc process, which had been discovered and put into practice almost simultaneously with Berthollet's chlorine process, decomposed salt by sulphuric acid, and sent the muriatic acid evolved into the atmosphere, causing a great nuisance to the neighbourhood.

Naturally, therefore, when Mr. William Gossage had succeeded in devising plant for condensing this muriatic acid, the manufacturers of chlorine reverted to the original process of Scheele, and heated manganese with the muriatic acid thus obtained. Since then the manufacture of chlorine has become a by-product of the manufacture of soda by the Le Blanc process, and remained so till very recently.

For a great many years the muriatic acid was allowed to act upon native ores of manganese in closed vessels of earthenware or stone, to which heat could be applied, either externally or internally. These native manganese ores, containing only a certain amount of peroxide, converted only a certain percentage of the muriatic acid employed into free chlorine, the rest combining with the manganese and iron contained in the ore, and forming a brown and very acid solution, which it was a great difficulty for the manufacturer to get rid of. Consequently, many attempts were made to regenerate peroxide of manganese from these waste liquors, so as to use it over again in the production of chlorine.

These, however, for a long time remained unsuccessful, because the exact conditions for super-oxydising the protoxide of manganese by means of atmospheric air were not yet known.

Meantime, viz., in 1845, Mr. Dunlop introduced into the works created by his grandfather, Mr. Charles Tennant, at St. Rollox, a new and very interesting method for producing chlorine, which was, in a certain measure, a return to the process used by the alchemists.

Indeed, the first part of this process consisted in decomposing a mixture of salt and nitre with oil of vitriol—a reaction that had been made use of for so many centuries! The chlorine so obtained is, however, not pure, but a mixture of chlorine with oxides of nitrogen and hydrochloric acid, which Mr. Dunlop had to find means to eliminate.

For separating the nitrous oxides, Mr. Dunlop adopted the method introduced 20 years before by the great Gay-Lussac in connection with vitriol-making, viz., absorption by sulphuric acid, and the nitro-sulphuric acid thus formed he also utilised in the same way as that obtained from the

towers which still bear Gay-Lussac's illustrious name, viz., by using it in the vitriol process in lieu of nitric acid. He then freed his chlorine gas from hydrochloric acid by washing with water, and so obtained it pure. This process possessed two distinct advantages—(1) it yielded a very much larger amount of chlorine from the same amount of salt, and (2) the nitric acid, which was used for oxidising the hydrogen in the hydrochloric acid, was not lost, because the oxides of nitrogen to which it was reduced answered the purpose for which the acid itself had previously been employed. But this process was very limited in its application, as it could only be worked to the extent to which nitric acid was used in vitriol-making.

The process has been at work at St. Rollox for over 50 years, and, as far as I know, is there still in operation; but I am not aware that it has ever been taken up elsewhere.

Within the last few years, however, several serious attempts have been made to give to this process a wider scope by regenerating nitric acid from the nitro-sulphuric acid and employing it over and over again to convert hydrochloric acid into chlorine. Quite a number of patents have been taken out for this purpose, all employing atmospheric air for reconvertng the nitrous oxides into nitric acid, and differing mainly in details of apparatus and methods of work, and several of these have been put to practical test on a fairly large scale in this neighbourhood, and also in Glasgow, Middlesbrough, and elsewhere. As I do not want to keep you here the whole afternoon, I have to draw the line somewhere as to what I shall include in this brief history of the manufacture of chlorine, and have had to decide to restrict myself to those methods which have actually attained the rank of manufacturing processes on a large scale. As none of the processes just referred to have attained that position, you will excuse me for not entering into further details respecting them.

Mr. Dunlop's process only produced a very small portion of the chlorine manufactured at that time at St. Rollox, the remainder being made, as before, from native manganese and muriatic acid, leaving behind the very offensive waste liquors I have mentioned before, which increased from year to year, and became more and more difficult to get rid of. The problem of recovering from these liquors the manganese in the form of peroxide Mr. Dunlop succeeded in solving in 1855.

He neutralised the free acid and precipitated the iron present by treating these liquors with ground chalk in the cold and settling out, and, in later years, filter-pressing the precipitate, which left him a solution of chloride of manganese, mixed only with chloride of calcium. This was treated with a fresh quantity of milk of chalk, but this time under pressure in closed vessels provided with agitators and heated by steam, under which conditions all the manganese was precipitated as carbonate of manganese. This precipitate was filtered off and well drained, and was then passed on iron trays mounted on carriages through long chambers, in which it was exposed to hot air at a temperature of 300° C., the process being practically made continuous, one tray at the one end being taken out of these chambers, and a fresh tray being put in at the other end. One passage through these chambers sufficed to convert the carbonate of manganese into peroxide, which was used in place of, and in the same way as, the native manganese.

The whole of the residual liquors made at the large works at St. Rollox have been treated by this process with signal success for a long number of years. For a short time the process was discontinued in favour of the Weldon process (of which I have to speak next); but after two years Dunlop's process was taken up again, and, to the best of my knowledge, it is still in operation to this day. It has, however, just like Mr. Dunlop's first chlorine process, never left the place of its birth (St. Rollox), although it was for a period of over 10 years without a rival.

In 1866 Mr. Walter Weldon patented a modification of a process proposed by Mr. William Gossage in 1837 for recovering the manganese that had been used in the manufacture of chlorine. Mr. Gossage had proposed to treat the residual liquors of this manufacture by lime, and to oxidise the resulting protoxide of manganese by bringing it into frequent and intimate contact with atmospheric air.

This process—and several modifications thereof subsequently patented—had been tried in various places without success. Mr. Weldon, however, did succeed in obtaining a very satisfactory result, possibly—even probably—because, not being a chemist, he did not add the equivalent quantity of lime to his liquor to precipitate the manganese, but used an excess. However, Mr. Weldon, if he was not a chemist at that time, was a man of genius and of great perseverance. He soon made himself a chemist, and having once got a satisfactory result, he studied every small detail of the reaction with the utmost tenacity until he had thoroughly established how this satisfactory result could be obtained on the largest scale with the greatest regularity and certainty.

He even went further, and added considerably to our theoretical knowledge of the character of manganese peroxide and similar peroxides by putting forward the view that these compounds possess the character of weak acids. He explained in this way the necessity for the presence of an excess of lime or other base if the oxidation of the precipitated protoxide of manganese by means of atmospheric air was to proceed at a sufficiently rapid rate. He pointed out that the product had to be considered as a manganite of calcium—a view which has since been thoroughly proved by the investigations of Goergen and others; and it is only fair to state that Weldon's process is not only a process for recovering the peroxide of manganese originally used, but that he introduced a new substance, viz., manganite of calcium, to be continuously used over and over again in the manufacture of chlorine.

Mr. Weldon had the good fortune that his ideas were taken up with fervency by Colonel Gamble, of St. Helens, and that Colonel Gamble's manager, Mr. F. Bramwell, placed all his experience as a consummate technical chemist and engineer at Mr. Weldon's disposal, and assisted him in carrying his ideas into practice. The result was that a process which many able men had tried in vain to realise for 30 years became in the hands of Mr. Weldon and his coadjutors within a few years one of the greatest successes achieved in manufacturing chemistry.

The Weldon process commences by treating the residual liquor with ground chalk or limestone, thus neutralising the free acid and precipitating any sulphuric acid and oxide of iron present. The clarified liquor is run into a tall cylindrical vessel, and milk of lime is added in sufficient quantity to precipitate all the manganese in the form of protoxide. An additional quantity of milk of lime, from one-fifth to one-third of the quantity previously used, is then introduced, and air passed through the vessel by means of an air-compressor. After a few hours all the manganese is converted into peroxide; the contents of the vessel are then run off; the mud, now everywhere known as "Weldon mud," is settled, and the clear liquor run to waste. The mud is then pumped into large closed stone stills, where it meets with muriatic acid, chlorine is given off, and the residual liquor treated as before.

You note that this process works without any manipulation, merely by the circulation of liquids and thick magnas which are moved by pumping machinery. As compared to older processes it also has the great advantage that it requires very little time for completing the cycle of operations, so that large quantities of chlorine can be produced by a very simple and inexpensive plant. These advantages secured for this process the quite unprecedented success that within a few years it was adopted, with a few isolated exceptions, by every large manufacturer of chlorine in the world; yet it possessed a distinct drawback, viz., that it produced considerably less chlorine from a given quantity of muriatic acid than either native manganese of good quality or Mr. Dunlop's recovered manganese. At that time, however, muriatic acid was produced as a bye-product of the Le Blanc process so largely in excess of what could be utilised that it was generally looked upon as a waste product of no value. Mr. Weldon himself was one of the very few who foresaw that this state of things could not always continue. The ammonia-soda process was casting its shadow before it. Patented in 1838 by Messrs. Dyar and Hemming it was only after the lapse of 30 years (during which a number of manufacturing chemists of the highest

standing had in vain endeavoured to carry it into practice) that this process was raised to the rank of a manufacturing process through the indomitable perseverance of Mr. Ernest Solvay of Brussels, and his clear perception of its practical and theoretical intricacies. A few years later, in 1872, Mr. Weldon already gave his attention to the problem of obtaining the chlorine of the salt used in this process in the form of muriatic acid. He proposed to recover the ammonia from the ammonium chloride obtained in this manufacture by magnesia instead of lime, thus obtaining magnesium chloride instead of calcium chloride, and to produce muriatic acid from this magnesium chloride by a process patented by Clemm in 1860, viz., by evaporating the solution, heating the residue in the presence of steam and condensing the acid vapours given off.

Strange to say, this same method had been patented by Mr. Ernest Solvay within 24 hours before Mr. Weldon lodged his specification. It has been frequently tried with many modifications, but has never been found practicable. Soon afterwards Mr. Weldon, with the object of reducing the muriatic acid required by his first process, proposed to replace the lime in this process by magnesia, and so to produce a manganite of magnesia. After treating this with muriatic acid and liberating chlorine, he proceeded to evaporate the residual liquors to dryness, during which operation all the chlorine they contain would be disengaged as hydrochloric acid and collected in condensers, while the dry residue, after being heated to dull redness in the presence of air, would be reconverted into manganite of magnesia.

This process was made the subject of long and extensive experiments at the works of Messrs. Gamble at St. Helens, but did not realise Mr. Weldon's expectations. It, however, led to some further interesting developments, to which I shall refer later on.

Those of you who were present at the last meeting of the British Association in this city will remember that this Section had the advantage of listening to a paper by Mr. Weldon on his chlorine process, and also to another highly interesting paper by Mr. Henry Deacon, of Widnes, "on a new chlorine process without manganese." And those of you who came with the then President of the Section (Professor Roscoe) to Widnes to visit the works of Messrs. Gaskell, Deacon, and Co., will well remember that at these works they saw side by side Weldon's process and Deacon's process in operation, and no one present will have forgotten the thoughtful, flashing eyes and impressive face of Mr. Deacon when he explained to his visitors the theoretical views he had formed as regards his process.

Mr. Deacon had made a careful study of thermochemistry, which had been greatly developed during the preceding decade by the painstaking, accurate, and comprehensive experiments of Julius Thomsen and of Berthelot, and had led the latter to generalisations, which, although not fully accepted by scientific men, have been of immense service to manufacturing chemistry.

Mr. Deacon came to the conclusion that if a mixture of hydrochloric acid with atmospheric air was heated in the presence of a suitable substance capable of initiating the interaction of these two gases by its affinity to both, it would to a very great extent be converted into chlorine with the simultaneous formation of steam, because the formation of steam from oxygen and hydrogen gives rise to the evolution of a considerably larger quantity of heat than the combination of hydrogen and chlorine. Mr. Deacon found that the salts of copper were a very suitable substance for this purpose, and took out a patent for this process in 1868. He entrusted the study of the theoretical and practical problems connected with this process to Dr. Ferdinand Hurter, who carried them out in a manner which will always remain memorable and will never be surpassed, as an example of the application of scientific methods to manufacturing problems, and which soon placed this beautiful and simple process on a sound basis as a manufacturing operation.

In the ordinary course of manufacture the major part—about two-thirds—of the hydrochloric acid is obtained mixed with air and a certain amount of steam, but other-

wise very little contaminated. Instead of condensing the muriatic acid from this mixture of gases by bringing it into contact with water, Mr. Deacon passed it through a long series of cooling pipes to condense the steam, which of course absorbed hydrochloric acid, and formed a certain quantity of strong muriatic acid. The mixture of gases was then passed through an iron superheater to raise it to the required temperature, and thence through a mass of broken bricks impregnated with sulphate or chloride of copper contained in a chamber or cylinder called a decomposer, which was protected from loss of heat by being placed in a brick furnace kept sufficiently hot. In this apparatus from 50 to 60 per cent. of the hydrochloric acid in the mixture of gases was burnt to steam and chlorine. In order to separate this chlorine from the steam and the remaining hydrochloric acid, the gases were washed with water and, subsequently, with sulphuric acid. The mixture now consisted of nitrogen and oxygen, containing about 10 per cent. of chlorine gas, which could be utilised without any difficulty in the manufacture of bleach liquors and chlorate of potash, and which Mr. Deacon also succeeded in using for the manufacture of bleaching powder, by bringing it into contact in specially constructed chambers with large surfaces of hydrate of lime. Within recent years this latter object has been attained in a more expeditious and perfect manner by continuous mechanical apparatus (of which those constructed by Mr. Robert Hasenclever and Dr. Carl Langer have been the most successful), in which the hydrate of lime is transported in a continuous stream by single or double conveyors in an opposite direction to the current of dilute chlorine, and the bleaching powder formed delivered direct into casks, thereby avoiding the intensely disagreeable work of packing this offensive substance by hand.

Mr. Deacon's beautiful and scientific process thus involves still less movement of materials than the very simple process of Mr. Weldon, because in lieu of large volumes of liquids he only moves a current of gas through his apparatus, which requires a minimum of energy. The only raw material used for converting hydrochloric acid into chlorine is atmospheric air, the cheapest of all at our command. The hydrochloric acid which has not been converted into chlorine by the process is all obtained, dissolved in water, as muriatic acid, and is not lost, as in previous processes, but is still available to be converted into chlorine by other methods, or to be used for other purposes.

In spite of these distinct advantages, this process took a long time before it became adopted as widely as it undoubtedly deserved. This was mainly due to the fact that the economy in the use of muriatic acid which it effected was at the time when the process was brought out, and for many years afterwards, no object to the majority of chlorine manufacturers, who were still producing more of this commodity than they could use. Moreover, there were other reasons. The plant required for this process, although so simple in principle, is very bulky in proportion to the quantity of chlorine produced, and as I have pointed out, the process only succeeded in converting about one-third of the hydrochloric acid produced into chlorine, the remainder being obtained as muriatic acid, which had in most instances to be converted into chlorine by the Weldon process; so that the Deacon process did not constitute an entirely self-contained method for this manufacture. This defect, of small moment as long as muriatic acid was produced in excessive quantities, was only remedied by an invention of Mr. Robert Hasenclever a short number of years ago; when by the rapid development of the ammonia-soda process the previously existing state of things had been completely changed, and when, at least on the Continent, muriatic acid was no longer an abundant and valueless by-product, but, on the contrary, the alkali produced by the Le Blanc process had become a by-product of the manufacture of chlorine. Mr. Hasenclever, in order to make the whole of the muriatic acid he produces available for conversion into chlorine by the Deacon process, introduces the liquid muriatic acid in a continuous stream into hot sulphuric acid contained in a series of stone vessels, through which he passes a current of air. He thus obtains a mixture of hydrochloric acid and air, well

adapted for the Deacon process, the water of the muriatic acid remaining with the sulphuric acid, from which it is subsequently eliminated by evaporation. In this way the chlorine in the hydrochloric acid can be almost entirely obtained in its free state by the simplest imaginable means, and with the intervention of no other chemical agent than atmospheric air. Since their introduction the Deacon process has supplanted the Weldon process in nearly all the largest chlorine works in France and Germany, and is now also making very rapid progress in this country.

Mr. Weldon, when he decided to give up his manganite of magnesia process, by no means relaxed his efforts to work out a chlorine process which should utilise the whole of the muriatic acid. While working with manganite of magnesia he found that magnesia alone would answer the purpose with out the presence of the peroxide of manganese. He obtained the assistance of M. Pechiney, of Salindres, and, in conjunction with him, worked out what has become known as the "Weldon-Pechiney" process, which was first patented in 1834.

This process consists in neutralising muriatic acid by magnesia, concentrating the solution to a point at which it does not yet give off any hydrochloric acid, and then mixing into it a fresh quantity of magnesia so as to obtain a solid oxychloride of magnesium. This is broken up into small pieces, which are heated up rapidly to a high temperature without contact with the heating medium, while a current of air is passing through them. The oxychloride of magnesium containing a large quantity of water, this treatment yields a mixture of chlorine and hydrochloric acid with air and steam, the same as the Deacon process, and this is treated in a very similar way to eliminate the steam and the acid from the chlorine. The acid condensed is, of course, treated with a fresh quantity of magnesia, so that the whole of the chlorine which it contains is gradually obtained in the free state.

The rapid heating to a high temperature of the oxychloride of magnesium without contact with the heating medium was an extremely difficult practical problem, which has been solved by M. Pechiney and his able assistant, M. Boulouvard, in a very ingenious and entirely novel way.

They lined a large wrought-iron box with fire-bricks, and built inside of this vertical fire-brick walls with small empty spaces between them, thus forming a number of very narrow chambers, so arranged that they could all be filled from the top of the box, and emptied from the bottom. These chambers they heated to a very high temperature by passing a gas flame through them, thus storing up in the brick walls enough heat to carry out and complete the decomposition of the magnesium oxychloride, with which the chamber was filled when hot enough.

Mr. Weldon himself called this apparatus a "baker's oven," in which trade certainly the same principle has been employed from time immemorial; but to my knowledge it had never before been used in any chemical industry. This process has been at work at M. Pechiney's large alkali works at Salindres, and is now at work in this country at the chlorate of potash works of Messrs. Albright and Wilson at Oldbury, a manufacture for which it offers special advantages. Mr. Weldon and M. Pechiney had expected that this process would become specially useful in connection with the ammonia-soda process by preparing, in the way proposed by Mr. Solvay and Mr. Weldon in 1872, a solution of magnesium chloride as a by-product of this manufacture; but instead of obtaining muriatic acid from this solution by Clenn's process, to treat it by the new process, so as to obtain the bulk of the chlorine at once in the free state. But M. Pechiney did no more succeed than his predecessors in recovering the ammonia by means of magnesia in a satisfactory way.

Quite recently, however, it has been applied to obtain chlorine in connection with the ammonia-soda process by Dr. Pick, of Czakowa, in Austria. He recovers the ammonia, as usual, by means of lime, and converts the solution of chloride of calcium, obtained by a process patented by Mr. Weldon in 1869, viz., by treatment with magnesia and carbonic acid under pressure, into chloride of

magnesium with the formation of carbonate of lime. The magnesium-chloride solution is then concentrated and treated by the Weldon-Pechiney process.

I have repeatedly referred during this brief history to the great change which has been brought about in the position of chlorine manufacture by the development of the ammonia-soda process, and have pointed out that the muriatic acid which for a long time was the by-product of the Le Blanc process, without value, thereby became gradually its main and most valuable product, while the alkali became its by-product.

I have told you how, very early in the history of this process, Mr. Solvay and Mr. Weldon proposed means to provide for this contingency, and how Mr. Weldon continued to improve these means until the time of his death. Mr. Solvay, on his part, also followed up the subject with that tenacity and sincerity of purpose which distinguishes him; his endeavours being mainly directed to producing chlorine direct from the chloride of calcium running away from his works by mixing it with clay and passing air through the mixture at very high temperatures, thus producing chlorine and a silicate of calcium, which could be utilised in cement making. The very high temperatures required prevented, however, this process from becoming a practical success.

I have already told you what a complicated series of operations Dr. Pick has lately resorted to in order to obtain the chlorine from this chloride of calcium. Yet the problem of obtaining chlorine as a by-product of the ammonia-soda process presents itself as a very simple one.

This process produces a precipitate of bicarbonate of soda and a solution of chloride of ammonium by treating natural brine or an artificially made solution of salt, in which a certain amount of ammonia has been dissolved, with carbonic acid. In their original patent of 1838, Messrs. Dyar and Hemming proposed to evaporate this solution of ammonium chloride, and to distil the resulting dry product with lime to recover the ammonia. Now all that seemed to be necessary to obtain the chlorine from this ammonium chloride was to substitute another oxide for lime in the distillation process, which would liberate the ammonia and form a chloride, which on treatment with atmospheric air would give off its chlorine and reproduce the original oxide. The whole of the reactions for producing carbonate of soda and bleaching powder from salt would thus be reduced to their simplest possible form; the solution of salt, as we obtain it in the form of brine direct from the soil, would be treated with ammonia and carbonic acid to produce bicarbonate, and subsequently monocarbonate of soda, the limestone used for producing the carbonic acid would yield the lime required for absorbing the chlorine, and produce bleaching powder instead of being run into the rivers in combination with chlorine in the useless form of chloride of calcium, and both the ammonia used as an intermediary in the production of soda and the metallic oxide used as an intermediary in the production of chlorine would be continuously recovered.

The realisation of this fascinating problem has occupied me for a great many years. In the laboratory I obtained soon almost theoretical results. A very large number of oxides and even of salts of weak acids were found to decompose ammonium chloride in the desired way; but the best results (as was to be clearly anticipated from thermo-chemical data) were given by oxide of nickel.

When, however, I came to carry this process out on a large scale, I met with the most formidable difficulties, which it took many years to overcome successfully.

The very fact that ammonium chloride vapour forms so readily metallic chlorides when brought in contact at an elevated temperature with metals or oxides or even silicates, led to the greatest difficulty, viz., that of constructing apparatus which would not be readily destroyed by it.

Amongst the metals we found that platinum and gold were the only ones not attacked at all. Antimony was but little attacked, and nickel, used for valves and taps, resisted very well if not exposed to too high a temperature, so that it could be, and is being, used for such parts of the plant as are not directly exposed to heat. The other parts of the apparatus coming in contact with the ammonium chloride vapour I ultimately succeeded in constructing

of cast and wrought iron, lined with fire-bricks or Doulton tiles, the joints between these being made by means of a cement consisting of sulphate of baryta and waterglass.

After means had been devised for preventing the breaking of the joints through the unequal expansion of the iron and the earthenware, the plant so constructed has lasted very well.

Oxide of nickel, which had proved the most suitable material for the process in the laboratory, gave equally good chemical results on the large scale, but occasionally a small quantity of nickel chloride was volatilised through local over-heating, which, however, was sufficient to gradually make up the chlorine conduits. We therefore looked out for an active material free from this objection. Theoretical considerations indicated magnesia as the next best substance, but it was found that the magnesium chloride formed was not anhydrous, but retained a certain amount of the steam formed by the reaction, which gave rise to the formation of a considerable quantity of hydrochloric acid on treatment with hot air. In conjunction with Dr. Eschellman (who carried out the experiments for me), I succeeded in reducing the quantity of this hydrochloric acid to a negligible amount by adding to the magnesia a certain amount of chloride of potassium, which probably has the effect of forming an anhydrous double chloride.

This mixture of magnesia and potassium chloride is, after the addition of a certain quantity of china-clay, made into small pills in order to give a free and regular passage throughout their entire mass to the hot air and other gases with which they have to be treated. In order to avoid as far as possible the handling and consequent breaking of these pills, I vaporise the ammonium chloride in a special apparatus, and take the vapours through these pills, and subsequently pass hot air through, and then again ammonium chloride vapour, and so on, without the pills changing their place.

The vaporisation of the ammonium chloride is carried out in long cast-iron retorts lined with thin Doulton tiles, and placed almost vertically in a furnace, which is kept by producer gas at a very steady and regular temperature. These retorts are kept nearly full with ammonium chloride, so as to have as much active heating surface as possible. From time to time a charge of ammonium chloride is introduced through a hopper at the top of these retorts, which is closed by a nickel plug. The ammonium chloride used is very pure, being crystallised out from its solution as produced in the ammonia soda manufacture by a process patented by Mr. Gustav Jarmay, which consists in lowering the temperature of these solutions considerably below 0° C. by means of refrigerating machinery. The retorts will therefore evaporate a very large amount of ammonium chloride before it becomes necessary to take out through a door at their bottom the non-volatile impurities which accumulate in them. The ammonium chloride vapour is taken from these retorts by cast-iron pipes lined with tiles and placed in a brick channel, in which they are kept hot, to prevent the solidification of the vapour to large upright wrought-iron cylinders, which are lined with a considerable thickness of fire-bricks, and are filled with the magnesia pills, which are, from the previous operation, left at a temperature of about 300° C. On its passage through the pills the chlorine in the vapours is completely retained by them, the ammonia and water vapour formed pass on and are taken to a suitable condensing apparatus. The reaction of the ammonium chloride vapour upon magnesia being exothermic, the temperature of the pills rises during this operation, and no addition of heat is necessary to complete it. The temperature, however, does not rise sufficiently to satisfactorily complete the second operation, viz., the liberation of the chlorine and the re-conversion of the magnesium chloride into magnesium oxide by means of air. This reaction is slightly endo-thermic, and thus absorbs a small amount of heat, which has to be provided in one way or another. I effect this by heating the pills to a somewhat higher temperature than is required for the action of the air upon them, viz., to 600° C., by passing through them a current of a dry inert gas free from oxygen heated by a Siemens-Cowper stove to the required temperature. I use for this purpose the gas leaving the carbouating plant of the ammonia-soda process.

This current of gas also carries out of the apparatus the small amount of ammonia which was left in between the pills. It is washed to absorb this ammonia, and, after washing, this same gas is passed again through the Siemens-Cowper stove, and thus constantly circulated through the apparatus, taking up the heat from the stove and transferring it to the pills. When these have attained the required temperature, the hot inert gas is stopped and a current of hot air passed through, which has also been heated to 600° C. in a similar stove. The air acts rapidly upon the magnesium chloride, and leaves the apparatus charged with 18 to 20 per cent. of chlorine and a small amount of hydrochloric acid. The chlorine comes gradually down, and when it has reached about 3 per cent., the temperature of the air entering the apparatus is lowered to 350° C. by the admixture of cold air to the hot air from the stove; and the weak chlorine leaving the apparatus is passed through a second stove, in which its temperature is raised again to 600° C., and passed into another cylinder full of pills which are just ready to receive the hot-air current. A series of four cylinders is required to procure the necessary continuity for the process.

The chlorine gas is washed with a strong solution of chloride of calcium, which completely retains all the hydrochloric acid, and is then absorbed in an apparatus invented by Dr. Carl Langer, by hydrate of lime, which is made to pass by a series of interlocked transporting twin-screws in an opposite direction to the current of gas, and produces very good and strong bleaching powder, in spite of the varying strength of the chlorine gas. The hydrochloric acid absorbed by the solution of calcium chloride can be heated this solution be readily driven out and collected.

This process has now been in operation on a considerable scale at our works at Warrington for several years, with constantly improving results, notably with regard to the loss of ammonia, which has gradually been reduced to a small amount. The process has fully attained my object, viz., to enable the ammonia soda process to compete, not only in the production of carbonate of soda, but also in the production of bleaching powder, with the Le Blanc process.

Nevertheless, I have hesitated to extend this process as rapidly as I should otherwise have done, because very shortly after I had overcome all its difficulties, entirely different methods from those hitherto employed for the manufacture of chlorine were actively pushed forward in different parts of the globe, for which great advantages were claimed, but the real importance and capabilities of which were and are up to this date very difficult to judge. I refer to the processes for producing chlorine by electrolysis.

During the first decade of this century, Humphry Davy had by innumerable experiments established all the leading facts concerning the decomposing action of an electric current upon chemical compounds. Amongst these he was the first to discover that solutions of alkaline chlorides, when submitted to the action of a current, yield chlorine. His successor at the Royal Institution, Michael Faraday, worked out and proved the fundamental law of electrolysis, known to everybody as "Faraday's Law," which has enabled us to calculate exactly the amount of current required to produce by electrolysis any definite quantity of chlorine. Naturally, since these two eminent men had so clearly shown the way, numerous inventors have endeavoured to work out processes based on these principles for the production of chlorine on a manufacturing scale, but only during the last few years have these met with any measure of success.

It has taken all this time for the classical work of Faraday on electro-magnetism to develop into the modern magneto-electric machine, capable of producing electricity in sufficient quantity to make it available for chemical operations on a large scale; for you must keep in mind that an electric installation sufficient to light a large town will only produce a very moderate quantity of chemicals.

In applying electricity to the production of chlorine various ways have been followed, both as to the raw materials and as to the apparatus employed. While most inventors have proposed to electrolyse a solution of chloride of sodium, and to produce thereby chlorine and caustic soda, I am not aware that up to this day any quantity of

caustic soda made by electrolysis has been put on to the market.

Only two electrolytic works producing chlorine on a really large scale are in operation to-day. Both electrolyse chloride of potassium, producing as a by-product caustic potash, which is of very much higher value than caustic soda, and of which a larger quantity is obtained for the same amount of current expended. These works are situated in the neighbourhood of Stassfurt, the important centre of the chloride of potassium manufacture. The details of the plant they employ are kept secret, but it is known that they use cells with porous diaphragms of special construction, for which great durability is claimed. There are at this moment a considerable number of smaller works in existence, or in course of erection in various countries, intended to carry into practice the production of chlorine by electrolysis by numerous methods, differing mainly in the details of the cells to be used; but some of them also involving what may be called new principles. The most interesting of these are the processes in which mercury is used alternately as cathode and anode, and salt as electrolyte. They aim at obtaining in the first instance chlorine and an amalgam of sodium, and subsequently converting the latter into caustic soda by contact with water, which certainly has the advantage of producing a very pure solution of caustic soda. Mr. Hamilton Castner has carried out this idea most successfully by a very beautiful decomposing cell, which is divided into various compartments, and so arranged that by slightly rocking the cell the mercury charged with sodium in one compartment passes into another, where it gives up the sodium to water, and then returns to the first compartment, to be re-charged with sodium. His process has been at work on a small scale for some time at Oldbury near Birmingham, and works for carrying it out on a large scale are now being erected on the banks of the Mersey, and also in Germany and America.

Entirely different from the foregoing, but still belonging to our subject, are methods which propose to electrolyse the chlorides of heavy metals (zinc, lead, copper, &c.) obtained in metallurgical operations or specially prepared for the purpose, among which the processes of Dr. Carl Hoepfner deserve special attention. They eliminate from the electrolyte immediately both the products of electrolysis, chlorine on one side and zinc and copper on the other, and thus avoid all secondary reactions, which have been the great difficulty in the electrolysis of alkaline chlorides.

All these processes have, however, still to stand the test of time before a final opinion can be arrived at as to the effect they will have upon the manufacture of chlorine, the history of which we have been following, and this must be my excuse for not going into further details. I have endeavoured to give you a brief history of the past of the manufacture of chlorine, but I will to-day not attempt to deal with its future! Yet I cannot leave my subject without stating the remarkable fact that every one of these processes which I have described to you is still at work to this day, even those of Scheele and Berthollet, all finding a sphere of usefulness under the widely varying conditions under which the manufacture of chlorine is carried on in different parts of the world.

Let me express a hope that a hundred years hence the same will be said of the processes now emerging and the processes still to spring out of the inventor's mind. Rapid and varied as has been the development of this manufacture, I cannot suppose that its progress is near its end, and that Nature has revealed to us all her secrets as to how to procure chlorine with the least expenditure of trouble and energy. I do not believe that industrial chemistry will in future be diverted from this Section and have to wander to Section A. under the agis of applied electricity. I do not believe that the easiest way of effecting chemical changes will ultimately be found in transforming heat and chemical affinity into electricity, tearing up chemical compounds by this powerful medium, and then to recombine their constituents in such form as we may require them. I am sure there is plenty of scope for the manufacturing chemist to solve the problems before him by purely chemical means, of some of which we may as little dream to-day as a few

years ago it could have been imagined that nickel would be extracted from its ores by means of carbon-monoxide.

At a meeting of the British Association which brings before us an entirely new form of energy, the Röntgen rays, which have enabled us to see through doors and walls and to look inside the human body; which brings before us a new form of matter, represented by argon and helium, which, as their discoverers, Lord Rayleigh and Professor Ramsay, have now abundantly proved, are certainly elementary bodies, inasmuch as they cannot be split up further, but are not chemical elements, as they possess no chemical affinity and do not enter into combinations—at a meeting at which such astounding and unexpected secrets of Nature are revealed to us, who would call in doubt that, notwithstanding the immense progress pure and applied science have made during this century, new and greater and farther-reaching discoveries are still in store for ages to come?

Alkali and Chlorine. W. Borchers. Zeits. f. Elektrochem. 1896, 3, 114—116.

An article setting forth the practical working cost of electrolysing solutions of alkaline salts.

Bleaching Solutions, Electrolytic Production of. Dingler's Polyt. J. 301, [10], 234.

KELLNER-HALLEIN'S apparatus for the electrolysis of brine, which was described and discussed before the meeting of the German Electro-Chemical Society, Stuttgart, June 25—27, is designed to meet the two requirements necessary for the successful commercial introduction of electrolytic bleaching solutions, namely, that the plant used in their production shall be capable of being worked by currents of the potential ordinarily supplied from central stations, thus obviating the necessity for special dynamos; and, secondly, that the cost of the installation shall be low. Dr. Kellner employs a single-ebonite tank, in which as many bi-polar electrodes are placed in series as the working potential will allow of. These electrodes are made of plates of ebonite provided with brush-like projections of platinum, which arrangement allows of the use of a high current density for a small weight of plate, and the brushes of the first and last electrodes are connected to the conductors supplying the current. The brine is admitted to the tank from below, and, passing between the electrodes, it leaves by two channels in the upper part of the tank, and after being cooled is returned to the vessel. The circulation is regulated so that the amount of active chlorine formed on the passage of the solution through the apparatus is 0.05 per cent., and the process is continued until the amount reaches 1 per cent. The apparatus is fully described in the Leipziger Monatschr. für Textilind. 9, 1895.—G. H. R.

Sulphoxyarsenates. Le Ray, W. McCay. Chem. Zeit. 1896, 20, 722.

THE author prepares the tertiary sodium salt of orthomono-sulpho-arsenic acid by melting an intimate mixture of equal parts of arsenious acid and sulphur in a large porcelain crucible at a gentle heat for 8—10 minutes. The melt is finely powdered, and digested for 24 hours at 0° with a solution of 1 part of sodium hydroxide in 7 parts of water. The insoluble residue is filtered off, and the filtrate slowly poured into an equal volume of 95 per cent. alcohol. Sodium sulphyarsenate immediately separates as a light yellow oil, which becomes crystalline when kept at 0° for some time; it is washed with a small quantity of 50 per cent. alcohol, pressed, and dried. The ammonium and potassium salts have also been prepared; the latter, however, could not be obtained in a crystalline condition. The barium and strontium salts were isolated by dropping a cold aqueous solution of Bouquet and Cloez's salt into the alkaline hydroxide, whilst $\text{Ba}_2\text{Na}_2(\text{AsO}_3\text{S})_2 + 17\text{H}_2\text{O}$ and the corresponding strontium compound were formed by adding the alkaline hydroxide to Preiss's salt.—J. Chlorates, Impts. in the Manufacture of, and in Means and Appliances therefor. J. Hargreaves, Farnworth-in-Widnes. Eng. Pat. 16,257, Aug. 30, 1895.

To obtain sodium chlorate, hydrated sodium carbonate is exposed to the action of chlorine in an absorbing tower in which lixiviation of the products is also conducted, the solid salts being supported by prismatic bearing pieces arranged to form inverted cones in the lower part of the tower. The chlorine enters at the side of these pieces, and is led around and through their interstices, and passes upwards through the charge above. Provision is made for draining off the liquid into a compartmented tank, one compartment of which contains pieces of soda resting on a grid. The chlorate liquor thus saturated is pumped to a tank on the top of the tower, whence it is allowed to flow down in a regulated manner on to the charge below. The salt (chiefly sodium chloride) removed from the tower is washed with steam and water in a centrifugal hydro-extractor. After the sodium chlorate liquor has passed through a series of lixiviating vessels kept at a high temperature, any suspended sodium chloride crystals are removed in a hydro-extractor, and the solution is concentrated to obtain crystallised sodium chlorate.

Potassium chlorate is preferably obtained from the chloride, a pasty mixture of which with lime or magnesia is chlorinated in an apparatus similar to that above described; but the treatment in lixiviating the chlorinated products is modified, very cold water or even ice being used in the process, owing to the greater solubility of the calcium or magnesium chlorides formed over the alkali chlorate at low temperatures. An economical method of constructing and bracing an absorbing tower is shown, and modifications of the described processes are given.—E. S.

Bleaching Liquid, Impts. in the Electrolytical Manufacture of [Cooling]. C. Kellner, Vienna, Austria. Eng. Pat. 17,525, Sept. 19, 1895.

By means of a pump, an 8 to 10 per cent. solution of sodium chloride is passed through the electrolytic vessel, so that 0.05 per cent. of chlorine is formed during each passage of the electrolyte through the apparatus. The electrolyte is passed into a vessel, where it is cooled in any convenient manner, and thence is returned to the decomposing cell, and so on, until the requisite concentration is reached, say, 1.5 per cent. of chlorine = 15 grms. per litre. The pipe connected with the cooling vessel is now closed, and the solution is passed by means of another pipe into the bleaching vessel; or by a suitable modification of the plant the action is made continuous, fresh salt solution passing into the decomposing cell as the bleaching solution is drawn off.—G. H. R.

Plates, Bricks, and Pipes for Filtering and like Purposes, Impts. in the Manufacture of Porous, Hard, and Acid-resisting. W. Schuler, Isny, Württemberg, Germany. Eng. Pat. 18,573, Oct. 4, 1895.

See under IX., page 729.

Carbonic Acid Gas, Impts. in the Manufacture of, by the Utilisation of Waste Product produced in Making Calcium and other Carbides. H. S. Elworthy, Bandra, Bombay, and P. D. Henderson, London. Eng. Pat. 19,445, Oct. 16, 1895.

When limestone and carbon are intensely heated, as in an electric furnace, to obtain calcium carbide, a large

quantity of carbon monoxide gas is evolved, which, under the present invention, is collected and passed over a suitable heated metallic oxide, such as cupric oxide. The carbonic acid gas thus produced is stored for utilisation, and the reduced copper or other metal is re-oxidised by heating in contact with air.—E. S.

Metallic Fluorides, Impts. in Manufacturing. W. Mills, London. Eng. Pat. 20,377, Oct. 29, 1895.

AMMONIUM fluoride is sublimed from a mixture of powdered fluorspar and ammonium sulphate heated to about 350° C. in a cast-iron retort, lined with calcium sulphate, and provided with an inverted cone-shaped lead cover or top, the concavity of which is kept full of water. To obtain the alkaline and earthy fluorides, it is preferred to treat a solution of the chloride first with gaseous ammonia and then with hydrofluoric acid gas. Sodium fluoride thus precipitated is anhydrous; but a hydrated and more soluble fluoride is obtained if aqueous H_2F be used. "Generally, when anhydrous fluorides are required, the thermal conditions of the reactions by which they are produced must be somewhat high." Sodium and potassium fluorides may also be obtained by similar treatment of their sulphates. To obtain the fluorides of metals, the salts of which are precipitable by ammonia, such as aluminium, chromium, magnesium, manganese and zinc, ammonium fluoride is added to a solution of the chloride or sulphate of the metal; or hydrofluoric acid is first added and then ammonia. Compound fluorides may also be prepared by precipitating in like manner solutions of mixed salts. Thus, cryolite may be obtained by treating the chlorides or sulphates of aluminium and sodium with ammonium fluoride. In some cases one of the salts is added in a dry state to the solution of the salt to be decomposed.—E. S.

Ammonia from Waste Nitrogenous Lyes or Gases, Impts. in or relating to the Production of. [From Sugar or Molasses Spirit.] H. H. Lake, London. From L. Sternberg, Jersey, New Jersey, U.S.A. Eng. Pat. 7002, March 31, 1896.

A CRUDE potassium aluminate is obtained by moulding into bricks a moistened mixture of bauxite (or clay) with lime and black ash, and after drying, crushing into pieces and heating to redness. This material is fed into an upright retort until the latter is nearly full. Another portion of the crude aluminate is incorporated with lye resulting from the extraction of sugar, at a density of 40° B., and with a stated proportion of bauxite, and when stiff, the mixture is pressed into blocks, which are dried, broken up, and then fed into the retort on the top of the previous charge of aluminate. The retort being heated, the gases given off from the lye compost are conducted downward through the glowing aluminate, which transforms the nitrogenous organic matters in the gases into ammonia, which is collected. As the process goes on the material is gradually removed from the bottom of the retort to make room for additions at the top of more of the lye compost, which, as it chars, replaces the removed aluminate and acts in the same manner, in aiding the production of ammonia. Nitrogenous gases from other sources may be similarly treated. A description is given of methods of utilising the by-products.—E. S.

Seaweed, an Improved Method of Treating, to obtain Valuable Products [Alginic Acid, "Tang Acid"] therefrom. A. Krøfting, Christiania, Norway. Eng. Pat. 11,538, May 27, 1896.

A process for preparing alginic acid (or as the inventor names it "tang acid") from seaweed. Seaweed is soaked, first of all, in dilute sulphuric acid (1 to 6 per cent.), which serves to decompose the intercellular binding material, and is then treated with sufficient of a solution of an alkali or alkaline carbonate to convert the whole into a kind of thin soup. The disintegration of the seaweed fibres takes place almost immediately. The liquid is then filtered and the tang acid precipitated therefrom by the addition of sulphuric acid. The product thus obtained, is free from nitrogen.—H. T. P.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Quartz Slate. Eng. and Mining J. 1896, 274.

See under Trade Rep., page 752.

PATENTS.

Plates, Bricks, and Pipes for Filtering and like Purposes, Impts. in the Manufacture of Porous, Hard and Acid-resisting. W. Schuler, Isny, Germany. Eng. Pat. 18,573, Oct. 4, 1895.

EQUAL parts of calcined Kieselguhr, powdered quartz and silicate of soda, are mixed in as dry a state as possible, moulded and pressed. After the product has hardened in air, it is burned at a temperature slowly rising to a clear red heat. The resulting brick or plate is porous and suitable for filtering. Organic material, such as sawdust, may be added to the mass before firing to increase the porosity of the finished article.—B. B.

Building Materials for Architectural and other Purposes, New or Improved Manufacture of Compositions suitable for Use as. J. Wilkinson, London. Eng. Pat. 9838, May 8, 1896.

A MIXTURE of glue, linseed oil, hydrochloric acid, sulphuric acid, plaster of Paris and lime, and another of zinc oxide, zinc chloride, sulphate of iron, borax and sal-ammoniac, as well as sundry dressings for the bricks to which these compositions are to be applied, are patented.—B. B.

Artificial Stone, Impts. in or relating to the Manufacture of. A. J. Boulton, London. From M. Thys, Brussels, Belgium. Eng. Pat. 12,169, June 3, 1896.

FOUR parts of sand and two of Portland cement are stirred together with glue, and the product is coloured by the addition of a second mixture consisting of 2 parts of cement and 1 part of colouring matter. The mass is pressed into tiles or similar objects, which are moistened every 2 or 3 hours for 3 or 4 days after pressing, and are finally kept in water for 4 days.—B. B.

Hydraulic Gypsum, Proceeding for the Production of Quick-setting (Hardening) Mortar of. L. Mack, Stuttgart, Germany. Eng. Pat. 12,125, June 6, 1896.

GYPSUM dead-burnt to anhydrous calcium sulphate may be caused to set within a reasonable time by the addition of sulphates of the alkali metals, caustic alkalis, magnesium sulphate or ammonium sulphate. As an example the use of 400 grams. of anhydrous sodium sulphate to 100 kilos. of calcined gypsum is quoted. The product is said to be more easily and cheaply manufactured than Keene's cement and to be suitable for general building purposes when the structure is not immersed in water.—B. B.

X.—METALLURGY.

Matte Smelting [Copper, Gold, and Silver] in California. H. Lang. Eng. and Mining J. 1896, 62, 78—79; 103—104.

A DESCRIPTION is given of the smelting works at Keswick, which were constructed for the purpose of reducing the ores of the Iron Mountain Mine. The process consists of three operations, viz.:—(1) Pyrites smelting; (2) Air conversion of the matte [bessemerising]; and (3) Electrolytic refining. The ores are of two kinds, viz., "oxides" and sulphides. The former are principally composed of ferric oxide containing a little silica and alumina, along with copper, but their chief value is in silver and gold, which amounts to several dollars per ton. The sulphides are richer in copper and poorer in gold and silver than the oxides. The copper in some parts of the mine runs to 10 per cent. Full details of the composition of the charges and of the plant are given, but it is expected that better results will be forthcoming. Present experience, however, shows that the protosulphate of iron slag is the best, and the nearer it approaches to this composition the

more favourable is the smelting. The introduction of clay or magnesia as silicate is prejudicial, and a quartz flux containing these substances diminishes the rate of concentration and decreases the fusibility of the charge. A clean white quartz or pure sandstone is the proper flux to use. The addition of lime, generally considered essential in pyritic smelting, is not practised at Keswick, where its introduction to the very basic ores of the district would necessitate the addition of a further quantity of silica, and so disturb the economy of the work.—A. W.

Gold, On the Liquefaction of Certain Alloys of. E. Matthey. Proc. Roy. Soc. 1896, 60, [359], 21—35.

THE author states that lead is far more effective as an agent of liquefaction than zinc, and that silver is undoubtedly the best solvent for the base metals, zinc and lead, when they are alloyed with gold.

He draws the following conclusions from his experiments:—

(1.) Alloys of gold with base metals, notably with lead and zinc, have the gold concentrated towards the centre and lower portions, which renders it impossible to ascertain their true value with even approximate accuracy.

(2.) When silver is also present, these irregularities are greatly modified. The "freezing-points" are very different when silver is present and when it is absent from the alloy.

(3.) This fact naturally leads to the belief that if the base metal present does not exceed 30 per cent, silver will dissolve it and form an uniform alloy with the gold. This conclusion is sustained by experiments described and illustrated in the paper.—A. S.

Iron Ores, The Roasting of, with the View to their Magnetic Concentration. H. Wedding. Iron and Steel Institute, Autumn Meeting, 1896. The Ironmonger, 423—428.

THE author first reviews the advantages *pro* and *con* of roasting the different kinds of iron ores in view of their subsequent reduction, and deals with the several equations representing the changes amongst the various oxides of iron which take place during such roasting. It is advisable that iron carbonates should be roasted before they pass to reduction in the blast furnace, as the heat required to drive off the carbon dioxide is produced and utilised more cheaply outside the furnace. Roasting carried out in the blast furnace is disadvantageous, because the reduction of the ores will take place in zones considerably deeper than after a preliminary roasting, and consequently an increased consumption of fuel is necessary. Akerman concludes that reduction by the roasting of a non-carboniferous ore, can never be of real advantage in the blast furnace, and that it is non-injurious where sintering does not occur after the de-oxidation, and the ore is not rendered more compact. The fact that oxide of iron ores can be more readily reduced after a slight preliminary roasting follows from the change in their physical condition. In the case of magnetites an oxidising roasting is always of advantage, especially in the case of those iron ores which are accompanied by so-called dark gangue stuffs, such as silicates containing ferrous oxides. The roasting of oxides, however, is not always of advantage viewed in the light of their facility for subsequent reduction, but it may be of much benefit when it is a question of preparing from a poor or impure ore, a richer and purer product by magnetic treatment.

The author next deals with the ores under five headings in respect to their preparation for this object. (1.) Magnetites do not need to be roasted for magnetic purposes. Such treatment, however, may be necessary to alter their physical state or to eliminate the sulphur; but they only lose their natural magnetic properties very slowly, whether the roasting is oxidising or reducing in character, except when they are maintained for a long time at a medium red heat with excess of air. The magnetic properties, however, come back on heating to a higher temperature. (2.) Spathic iron ores by suitable roasting yield the magnetic oxide direct. By roasting in a neutral atmosphere the "ignition" magnetic oxide Fe_3O_4 is obtained and in a moderately oxidising atmosphere the magnetic oxide Fe_2O_3 . If, however, the carbon dioxide is once

eliminated, both these oxides pass readily under the action of the oxygen of the air into the non-magnetic ferric oxide Fe_2O_3 . Success therefore depends, as to the production of the magnetic oxide, upon roasting the carbonates with exclusion of air, or, if this be impossible, with a minimum quantity thereof. (3.) Red hematites may be converted into magnetic oxide in two different ways—(a) By heating strongly in the absence of air, and (b) By heating under the action of reducing gases; hydrogen is the most suitable at low temperatures, and carbon monoxide at high temperatures. (4.) Brown iron ores require the water of hydration to be eliminated before reduction. The residue then behaves as a red hematite would, but the reduction proceeds far more readily under the influence of the reducing gases, owing to the more porous character of the dehydrated ore. (5.) Pyritic ores must first be deprived of their sulphur contents, and then the resulting oxide behaves as a red hematite, except that it is a little more difficult to reduce. However, pyrites is only used in practice when it contains copper, and the purple ore resulting from the extraction of the copper is pure enough to dispense with any magnetic separation. The size of the ore and the requirements of the furnaces to be used for these purposes with the different kinds of material are briefly discussed.—A. W.

Steel, Presence of Fixed Nitrogen in. F. W. Harbord and T. Twynam. Iron and Steel Institute, Autumn Meeting, 1896. The Ironmonger, 433—434.

NITROGEN appears to exist in steel in two conditions, since, on solution of the steel in a suitable solvent, or by boring under water or mercury, a far larger amount of nitrogen is obtained than can be found when the fixed nitrogen only is estimated. It appears probable that this nitrogen is merely mechanically occluded in the metal, whilst the fixed nitrogen exists in combination with some other element present, either iron, manganese, or carbon, but probably the first named. With a view to ascertain if the nitrogen could indicate the cause of failure, the authors have examined samples of steel which have failed under varying conditions, when neither analytical nor mechanical tests would do so. They have, however, failed to trace any connection between the amount of nitrogen and the good or bad quality of the steel, and therefore conclude that nitrogen, in the proportion in which it is found in commercial steel, has no detrimental effect.

Analyses of two tubes of Swedish steel, one bad and the other good, showed the latter to contain more nitrogen than the former. The results of the analyses of other kinds of steel show the percentages of nitrogen to range from 0.007 to 0.027. It was also thought that the well-defined nitride of manganese, Mn_3N_2 , might be the cause of the beneficial action of manganese in steel, but in this case also, the results did not lead to any positive conclusions.—A. W.

Carbon, A Note on "the Missing." T. W. Hogg. Iron and Steel Institute, Autumn Meeting, 1896. The Ironmonger, 437—439.

THE "Missing Carbon" is the term used to denote that portion of the carbon in water-quenched steel which is found by taking the difference between Eggertz' test in the normal or annealed steel, and in the same steel in its hardened condition. Its precise nature has yet to be discovered, but the author has for some time used it as a rough measure of the quantity of the carbon which effects the hardening. On treating steel with an excess of nitric acid of moderate strength, the freshly liberated or nascent carbon or carbide enters into combination with the gases evolved at the same time. A nitro-carbon compound is thus formed, which passes into solution upon the application of heat, with the well-known brown colour. A continued heating causes the complete destruction of this colouring matter, with the slow evolution of carbon dioxide, small quantities of cyanogen compounds, and a colourless viscid decomposition product. Nitro-carbon compounds obtained from the same steel in its cast and annealed conditions by treating the borings with a large excess of cold

nitric acid (1·2 sp. gr.) gave the following figures on analysis:—

	Annealed.	Cast.
	Per Cent.	Per Cent.
Iron.....	73·73	2·54
Carbon.....	8·43	10·41
Water.....	7·26	22·46
Nitrogen.....	3·20	8·25
Oxygen (by diff.).....	7·38	17·40

In these analyses the water obtained in the combustion has not been calculated to hydrogen which might be present to a considerable extent not in combination with oxygen. The nitro compounds gradually decompose, even at the ordinary temperature, and this is shown by a series of experiments, wherein a current of pure dry air was passed over them for a definite period at different low temperatures, and the resulting gases absorbed in calcium chloride and potash tubes. The increase in weight in the tubes was in each case greater than the loss, but not sufficient to represent the complete oxidation of the elements. The potash contained small quantities of cyanogen, and only a portion of the total is due to the carbon dioxide. Most of the absorption is evidently due to gradual evolution of nitrogen oxides.

The results of treating steel with nitric acid of the test strength are sufficiently distinctive in character to be classified into four divisions, as follows:—(a) amorphous carbon, which is black and insoluble; (b) normal carbide, which is black, magnetic, and insoluble; (c) dissolved carbide, a brown, insoluble nitro-carbon compound; and (d) unknown carbide, which either is immediately decomposed as CO_2 , or forms a colourless compound. The nitro-compounds are very unstable. The black magnetic substance (b) is decomposed by hot nitric acid; the iron passes into solution, and the brown nitro-carbon compound thus formed dissolves. The carbide (c), when dissolved in the steel, forms at once the brown nitro-carbon compound with the cold acid. The unknown carbide (d) is that which is considered identical with the so-called hardening carbon. Analyses of the total carbon and the carbon by colour test in a series of hardened steels varying in percentage from 0·10 to 6·50 total carbon, show that "the missing carbon" can attain as much as 58·33 per cent. of the whole amount present. With the highest carbon steel there was none. It would appear that the steels which seem to be able to retain the larger proportion of their carbon in this condition are, with one or two exceptions, those which lie between 0·70 and 1·00 per cent., the quantity in all these cases being above 50 per cent.—A. W.

Alumina, Manufacture of [for Aluminium]. J. Sutherland. Inst. Mech. Eng. 1896. Through Engineering, 1896, 62, 291—292.

This is an account of the application of Bayer's process at the Factory at Larnie Harbour. The raw material is bauxite from County Antrim, with an average of 56 per cent. of alumina, 3 per cent. of ferric oxide, 12 per cent. of silica, 3 per cent. of titanic acid, and 26 per cent. of water. The ore is crushed in a disintegrator to $\frac{1}{2}$ -in. cubes, and is riddled through a $\frac{3}{4}$ -in. mesh; that which passes the sieve is delivered into a calciner in which all organic matter is burned off, so that it may not interfere with the subsequent precipitation of alumina from its solution in caustic soda. An excessive temperature must, however, be guarded against, lest the material should be rendered too insoluble. The calciner is of the Oxland and Hocking type, and consists of an iron tube 33 ft. long and 3½ ft. in diameter, lined with fire-brick, and mounted on rollers so that it may be revolved. It is inclined at an angle of 1 in 25, and is heated by a fireplace at the lower end, from which the hot gases pass through the tube to a chimney at the upper end. The ore is fed continuously into the tube at the upper part and, as the tube revolves, passes slowly to the other end where it is discharged upon a plate with a hole just large enough to allow the particles to pass. From thence it is conducted by a shoot to a revolving cooling tube, 30 ft. long and

2½ ft. in diameter, which is placed below, and inclined in the opposite direction to, the calcining tube. Here it is cooled by means of a current of cold air from a fan. A spiral conveyor conducts the cold ore to a second crusher where it is broken down so that it all passes a sieve of 30 meshes per linear inch, and is stored for use.

The crushed alumina is treated in pressure kiers with caustic soda solution of 1·45 sp. gr. The kiers are constructed of mild steel plates $\frac{1}{2}$ in. thick, and are 11 ft. long and 5 ft. in diameter, with a 3-in. horizontal shaft passing through stuffing boxes in the end walls. The shaft is provided with eight 16 in. × 9 in. paddles, which serve as agitators. The kier has charging and discharging openings, and its jacket has a safety-valve, a steam inlet, and a water outlet connected with a steam trap. The soda solution is first introduced in the proper proportion, and the ore (usually 3 tons) is slowly added by means of an elevator, the paddles being kept at work throughout this time to ensure thorough admixture. After closing the charging opening, steam is turned on into the jacket, and the pressure is slowly raised to 70—80 lb., at which it is maintained for two or three hours, until decomposition is complete. The discharge cock is then opened and the red mud is blown out by the pressure in the kiers into tanks at the top of the building. Here water is added to reduce the specific gravity of the liquid to 1·23, and the solution of aluminate of soda is separated by filter-presses from the red deposit that is left. The cakes are washed before removal from the filter press, and are then carried away; no use has yet been found for them. The filtrate is now filtered again through wood pulp contained in lead-lined vats with sloping sides 10 ft. long × 6 ft. broad × 3 ft. deep, with a ledge round the inside, 6 in. from the bottom, on which is placed a frame carrying a sieve of $\frac{1}{8}$ -in. mesh. Two of these filters are superposed; about 50 lb. of wood pulp is boiled with water to a thin pulp, and is run on to the sieve in each filter. It soon settles down, and is ready to receive the filtrate, from which it separates the fine solid matter which it contains. This second filtration is necessary for the production of pure aluminate of soda.

The aluminate solution was formerly decomposed by carbonic acid, but this involved a subsequent regeneration of the soda from the carbonate. By the Bayer process the aluminate is run into circular decomposing tanks 13 ft. in diameter and 20 ft. high, provided with agitators. The precipitation of the aluminium hydroxide is effected by the addition of an excess of the same material. A sufficient quantity of the hydroxide is left in the decomposer, the aluminate of soda is introduced, agitation is commenced, and within 36 hours 70 per cent. of the alumina in combination with the soda will have been precipitated from the solution. The agitation is stopped, the hydroxide is allowed to settle, and the liquor with its undecomposed portion is run off to the weak-liquor tanks. When as much as possible of the clear liquor has thus been decanted, the hydrate mud is filter-pressed, sufficient being left, however, in the decomposer to accomplish the precipitation of the next batch of liquid. The filtrate is conveyed to the weak-liquor tanks. The pressed cakes are washed free from soda *in situ*, and compressed air is then forced through them to expel as much water as possible. The air-compressors deliver the air at a pressure of 80 lb. per sq. in. The pressed alumina is conveyed mechanically to calcining furnaces. This furnace has a bed 20 ft. by 6 ft., and is fired by Dowson gas produced in generators placed outside the main building. The products of combustion pass between an arch over the hearth and a drying tray above, on which the cakes of alumina receive a preliminary drying before they are admitted to the hearth. It is necessary that the product shall be perfectly dry, if it is to be used for the manufacture of aluminium in the electric furnace. A low temperature would suffice for this; but the alumina is usually heated up to 2,000° F., so that it may become crystalline, in which state it is less prone to reabsorb moisture from the air subsequently. After calcination, the alumina is spread upon a tiled floor to cool.

The weak liquors from the decomposers have a specific gravity of 1·2, and must be concentrated in a triple-effect evaporator to the specific gravity of 1·45 before they can be used to attack the calcined bauxite. The water evaporated

from the solution has a temperature of 180° F., and, being pure, is used for washing the hydroxide and for feeding the boiler. All the drainage of the factory is collected in a concrete tank placed in the yard, and is pumped back to be used for washing the red mud, for dissolving soda, &c., so that any soda or aluminate that may have leaked away is recovered.—W. G. M.

Blende, Examination of the Reactions Occurring in the Metallurgical Treatment of. E. Prost. Bull. de l'Assoc. Belge des Chim., 10, [5], 212–225.

HOWEVER carefully the roasting process may be performed, the sulphur which always remains behind depends upon the initial proportion of calcium and magnesium carbonates, and lead sulphide in the blende, as well as on the silica present, the latter favouring the liberation of the sulphur combined with the lead. Both zinc and iron sulphides are almost completely converted into oxides, lead sulphide becomes sulphate or silicate, and lime is largely changed into gypsum.

The author examined several samples of roasted blende, by extracting the soluble sulphates with cold water and estimating the sulphuric acid, zinc, calcium, and magnesium in the solution. The results tend to show that only a small portion of the zinc (e.g., 0.20 per cent. out of 57.80 per cent. in the blende) is in the state of sulphate, whereas nearly the whole of the lead (5.02 out of a total 5.60 per cent.) is in that condition.

That the oxide of zinc enters into combination with iron oxide in the roasting furnace (chiefly forming ZnFe_2O_4) is indicated by the results obtained when the roasted blende was heated with ammonium tartrate for the extraction of zinc, viz.:—

No.	Iron.	Zinc (Total).	Zinc extracted by Ammonium Tartrate.
	Per Cent.		
1	15.29	45.29	28.82 = 63.64 per cent. of the total Zn.
2	1.50	62.86	59.18 = 95.42
3	5.28	57.80	43.16 = 74.67

Some $2\frac{1}{2}$ to 3 per cent. of zinc remains in the residue after distillation, and attention was given to the state of combination in which this residual zinc exists. After removing the ferruginous matter from the residue by a magnet the remainder was attacked by increasingly concentrated acid solvents. It was found that out of the 4.76 per cent. of zinc present, 2.36 at least was in the condition of sulphide, thus confirming in some measure the statement of Voigt (Zeits. angew. Chem. 1889, 571) although the results did not entirely agree with his. The divergence, as also the occurrence of cases wherein the zinc in the residue is chiefly found as oxide, is probably attributable to variations in the composition of the ore, the state of the mixture, and the temperature of the furnace, &c.—C. S.

Mercury Ores, Treatment of, in the Asturias, Spain. Eng. and Mining J. 1896, 62, 149, 150.

THE new types of furnace which have been in use are the Livermore, the Rodriguez, and the Gasenc-Rodriguez. Descriptions and drawings of each of these furnaces are given, together with the charges employed in them. Careful trials with the last-named furnace showed that the average quantity of the quicksilver obtained was 96.88 per cent. of that in the ore. The necessity for the careful treatment of the ore is shown by the fact that the average percentage of quicksilver in it is as low as 0.7.

The arsenical product which condensed with the quicksilver in the condensers on working a charge of ore in the Gasenc-Rodriguez furnace, has the following approximate composition:—Mercury, 14.0; sulphate of mercury, 0.87; arsenious acid, 62.78; arsenious sulphides, 0.45; volatile oils, 2.0; water, 1.5; carbon, 1.5; and mineral matters, 16.9 per cent. This is mixed with lime, washed with a flowing stream of water, mixed with 0.3 per cent. of both coke and clay, made into briquettes, and again distilled. The product then condensed has the following composition:—Arsenious

acid, 90.73; sulphuric acid, 0.27; mercury, 8.61; lime 0.17; and carbon, 0.22 per cent. After forming into briquettes, this is again distilled with a higher percentage of coke and a sufficiently high proportion of arsenic to enable it to be made into orpiment, when the condensed product contains only a trace of quicksilver (the bulk having run off to the proper receptacles). The assay of the ores is carried out by the electrolytic process, since the lowness of their grade renders it difficult to obtain exact results with the old amalgamation process.—A. W.

Pure Molybdenum, Preparation and Properties of. H. Moissan. Eng. and Mining J. 1896, 99.

THE author prepared metallic molybdenum in fused masses, practically free from carbon, by the following method:—Pure ammonium molybdate, finely powdered, is heated in quantities of 1 kilo., in a covered clay crucible for $1\frac{1}{2}$ hours in a Perrot gas furnace. The ammonia is volatilised, leaving in the crucible, molybdic oxide (MoO_3) as a bluish-gray powder, the yield being 76 to 78 per cent. of the weight of the salt treated. The oxide so obtained is mixed with sugar-charcoal in quantity insufficient for complete reduction; 300 of oxide to 30 of charcoal. The mixture is packed into a carbon crucible and subjected to the calorific action of the arc produced by a current of 600 amperes at 60 volts for a period of six minutes, care being taken to keep a layer of solid material in contact with the crucible, which would be rapidly attacked if the charge was completely fused. Under these conditions more than 1 kilo. may be easily obtained in an hour.

Molybdenum, thus obtained, is a tolerably soft metal, does not scratch glass, can be easily filed and polished, and is malleable when hot, and its specific gravity is 9.01. If a fragment be embedded in charcoal and heated for several hours at about 1500° C., cementation ensues, a small quantity of carbon is taken up and the metal becomes harder than glass. The resulting metal, when heated to 300° C. and chilled in cold water, becomes brittle and so hard that it scratches quartz. The metal itself is but slightly oxidisable in the air at temperatures below a dull red heat, and becomes coloured on the surface like steel. At about 600° C. it begins to oxidise and is converted into molybdic acid. The action of oxygen is similar but more rapid, so that combustion takes place with vivid incandescence.

When the reduction of the oxide in the electric furnace is effected with excess of carbon, substances containing carbon, both in combined and graphitic condition, as in cast iron, are readily obtained. Their density varies from 8.6 to 8.9. When saturated with carbon, the metal is more fusible than pure molybdenum and is intensely hard; but when the proportion is only 2.5 per cent., it is difficult to break with a hammer. The point of saturation seems to correspond to 5.88 per cent. or the formula Mo_3C . This runs very liquid and may easily be cast into ingots weighing from 8 to 10 kilos. The liquid metal dissolves carbon very readily, but the excess above this quantity separates out on solidification as graphite. The carburised metal, like cast iron, may be rendered superficially malleable by closely covering it with powdered oxide of molybdenum and heating for several hours; this produces a skin of the pure metal.

The author considers that the volatility of its oxide is likely to render molybdenum of value as a deoxidising agent in steel works in the place of manganese or aluminium, for although the latter is an energetic agent, it has the inconvenience of giving a solid and infusible oxide, whilst the molybdenum oxidising would produce a stirring action in the bath, leaving nothing behind, or if in slight excess, it would have no effect on the malleability and tempering properties of the steel. For this purpose, however, the solid metal would be necessary, as that in a powdered form produced by reduction of the oxide with hydrogen, is useless, merely burning to waste on the surface of the bath without affecting the metal below.—A. PATENTS.

Bluestone and other Sulphurised Ores [Separation by Ferric Chloride], Impts. in the Treatment of. J. C. Butterfield, London. Eng. Pat. 9052, May 7, 1895.

THE finely ground ores are treated in tanks with a hot solution of ferric chloride, by which means the copper, lead, antimony, &c. are dissolved, whilst the sulphur, gold, and gangue are left as insoluble residues. The solution is then drawn off into settling tanks. In the first series, part of the lead chloride is deposited and the remainder in the second series. From the clear liquors, the copper, antimony, &c. are precipitated on metallic iron and may be separated by any known methods. The solution is then heated and regenerated by blowing air through it. To lessen the "frothing" during the blowing, a little petroleum is added. The ferric hydrate produced in this operation is then removed by filtration through asbestos, and after thorough washing, may be converted into pigments by known methods. The filtrate is employed for lixiviating a new portion of ore.

The insoluble residues are dried and heated to dull redness in retorts so as to separate and condense the arsenic and sulphur. The earthy residue containing the gold is then mixed with lime or other suitable fluxing material, and with sulphate or sulphide of lead and smelted to a regulus which is washed, ground, and treated as before with ferric chloride solution to separate lead as chloride. The residue from this operation is distilled as before but this time yields a button of lead containing all the gold (and silver), which may be recovered by cupelling.

The sulphate of lead required for the process is made from the chlorides deposited from the various liquors.—J. H. C.

Copper, The Extraction of, from Sulphuretted Ores or Compounds; An Improved Process for. C. James, Swansea. Eng. Pat. 15,159, July 8, 1896.

A PORTION of the ore is converted into a matte of from 70—75 per cent. of copper, which is then crushed and calcined. Three parts of this calcined product are then mixed with 2 parts of raw sulphuretted ore—more or less, as may be determined by assay,—and treated in the furnace as in Eng. Pat. 18,898 of 1890, so as to produce a "purple" or "blister" copper.—J. H. C.

Argentiferous and Auriferous Copper-Ores, Mattes, or Compounds, An Improved Process [Partial-Oxidation] for the Reduction of. C. James, Swansea. Eng. Pat. 14,957, July 6, 1896.

PART of the ores, &c. are calcined or oxidised by adding a highly oxidising salt to the charge, another part is added in an uncalcined condition, the proportions being predetermined by assay. The precious metals are concentrated in the metallic copper produced by the mutual reaction while in the furnace, as described in Eng. Pat. 18,898 of 1890, and may be subsequently separated by electrical or other known methods. Silica is added when lead is present, so as to remove it in the form of a slag which is free from the precious metals. This slag after being freed from lead, is again employed in the earlier stages of the process.—J. H. C.

Precious Metals, Impts. [Cyanides and Electricity] in Obtaining, from Solutions. J. S. MacArthur, Pollockshields. Eng. Pat. 16,634, Sept. 5, 1895.

THE improvements refer chiefly but not exclusively to cyanide solutions. The metals are precipitated by means of an electric current applied in connection with anodes and cathodes of iron or steel plates coated with graphite, lead oxide or other suitable substance.—J. H. C.

Metal Sheets, Impts. in Preparing for the Purpose of Galvanizing them, or otherwise Coating them with Metal or Metallic Alloy. Davies Bros. and Co., Lim., E. A. Davies, and S. T. Thomas, all of Wolverhampton. Eng. Pat. 17,932, Sept. 25, 1895.

THE sheets are first passed through a furnace so as to raise a scale upon their surfaces. The scale is then removed by means of revolving metallic brushes or rolls and the plates are finally pickled in the usual way. Reference is made to a previous patent (see this Journal, 1895, 973).—J. H. C.

Calcining Furnaces [Desulphurising], Impts. in. A. H. Wetley Butte, Montana. Eng. Pat. 9560, May 5, 1896.

A SERIES of roasting hearths placed one above another, are connected in such a manner as to form a continuous chamber for the passage of the ore and the heated gases, which move in opposite directions. The hearths are provided with rakes or stirring devices, and these are operated through longitudinal slots in the sides of the furnaces.—J. H. C.

Roasting Furnaces, Impts. in. B. T. Lacy, San Francisco. Eng. Pat. 15,682, July 15, 1896.

THE improvements relate to mechanical furnaces and chiefly to the travelling rables, and are purely mechanical.—J. H. C.

Precious Metals, A Process for Extracting from Refractory Ores. J. Woodford, London. Eng. Pat. 12,129, June 3, 1896.

THE crushed ore, whether raw or roasted, is intimately mixed with antimony oxides and pulverised fuel, and then fused in a cupola or other suitable furnace, so as to form an alloy of antimony and gold, which is tapped off and treated in an oxidising furnace, having a bed glazed with a mixture of borax and sulphate of soda. The antimony passes away as fume, while the precious metal remains on the furnace bed. The operation is repeated until the bed is sufficiently charged.

The fume is drawn off, condensed by water-spray, and used over again after drying.—J. H. C.

Desilverisation of Lead [Squeezing out Unalloyed Lead], Impts. in and relating to. W. H. Howard, Pueblo, U.S.A. Eng. Pat. 15,542, July 14, 1896.

THE zinc crusts produced in the Parkes process are subjected to pressure whilst still hot, whereby the unalloyed lead is squeezed out before it has time to cool and harden. The resulting alloy is considerably reduced in weight and bulk, and becomes consequently much richer in silver.—J. H. C.

Iron Blast-Furnace Gases, Impts. in Apparatus for Rendering Available for Working Gas-Motor Engines. B. H. Thwaite and F. L. Gardner, London. Eng. Pat. 15,684, July 15, 1896.

A DOUBLE valve is connected to the bell-hopper of the furnace, so as to control the gases in their passage to a receiver, and to prevent the formation of explosive mixtures by admixture of air. The gases are led to dust-depositing chambers containing obliquely-placed screens of wire gauze, which are moved rapidly up and down by means of eccentrics or cranks, so that the dust deposited in the meshes may be shaken off. The valve-stems, screen-roads, and other working parts are "sealed" with mercury or other liquid where required. The deposit of dust may be assisted by electric discharges.

From the dust chambers the gases are drawn, by means of a fan, through washing and filtering apparatus, and finally to an automatic gas-regulator.

An automatic electrical signalling apparatus for informing the attendant when the pressure in the furnace varies beyond certain limits is also provided.—J. H. C.

Magnetic Oxide of Iron, Impts. in the Process of converting Ferric Oxide into. R. H. Peak, Florida, U.S.A. Eng. Pat. 15,965, July 18, 1896.

The ferric oxide is finely ground, heated in an air-tight vessel, and then allowed to cool without access of air.

—J. H. C.

Ferro-Sodium Fluxes [Iron and Steel], Impts. in. W. J. May, Kingston-on-Thames. Eng. Pat. 17,901, Sept. 25, 1896.

CAST-IRON or steel is melted and poured on to beds composed of iron or steel borings, intimately mixed with a sodium salt, and immediately covered with a sufficient thickness of a similar mixture. The claim does not include the use of chloride of sodium.—J. H. C.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A).—ELECTRO-CHEMISTRY.

Cement and Concrete, On the Electrical Conductivity of. Dr. St. Lindeck. Elektrotech. Zeits. 1896, 180; Proc. Inst. Civil Eng. 1896, [3], 66.

THE author refers to the leakage of current upon electrical railways where the rails are used as the return circuit, and, after alluding to the damage done to metal pipes laid underground, and also to the disturbance occasioned to electrical laboratories in the neighbourhood, discusses means whereby such leakage may be prevented or materially diminished.

He quotes Dr. Ulbricht and Dr. Kallmann as considering that the rails should be insulated as well as possible from the earth, and cites the fact that the American practice of fixing the rails either upon longitudinal sleepers or cross sleepers, in each case of creosoted wood, appears to give better results than the German practice of laying the rails in concrete.

Cement and Cement-Concrete.—Experimental blocks were used, 15.75 ins. long by 3.94 ins. square, and sheet-iron electrodes with holes in were fixed in these while in a soft state. At least two blocks were used of each kind; and neat cement, as well as various classes of concrete, were tested.

The results are calculated in the original for a cubic decimetre of the material, and from the data it appears that, while the resistance per cubic foot of the pure cement blocks dry is about 144 ohms, this falls as low as 43 ohms after immersion for 22 hours in water, and rises to 820 ohms after being exposed to a heat of 212° F. The greater the admixture of sand or gravel, the higher the resistance becomes, until, with 1 of cement to 7 of gravel, the resistance, dry, reaches about 1,800 ohms, after immersion falls to 72 ohms, and, after exposure at 212° F., rises to about 2,000,000 ohms for a time.

It is obvious, therefore, that such a concrete rail-bed favours the escape of current to earth, especially if the surface of the road consist of asphalt, which prevents the concrete from drying.

The retention of water by the concrete is clearly shown with the test pieces, made with 1 part of cement to 7 parts of gravel. These gave in an air-dried state a resistance of 5,000 ohms, while after exposure to a heat of 212° F. in an oven the same pieces gave a resistance of from 6 megohms to 7 megohms.

If the highest result obtained for air-dried concrete be taken at about 1,670 ohms per cubic foot, an insulation resistance of about $\frac{1}{2}$ ohm per mile of road is obtained.

Asphalt-Concrete.—Ulbricht also drew attention to the so-called "asphalt-concrete," which has been used for building purposes in Dresden. This consisted of 50 per cent. of broken stone, 20 per cent. of coarse gravel free from loam and sand, 12 per cent. of asphalt, 8 per cent. of coal-tar pitch, and 10 per cent. of German coal-tar. The results obtained were so high that it was doubtful whether the current passed through the material or leaked over the surface.

One cubic decimetre block made with syenite gave when dry an insulation resistance of 280,000 megohms. It was then immersed in water for two hours, and 2½ hours afterwards gave an insulation resistance of 160,000 megohms; while, after six weeks' immersion, it gave 170,000 megohms, and similar results were obtained with the other blocks. The author therefore believes that, if this asphalt-concrete be used, the leakage of current would be very trifling, and the cost could be kept down by using merely a thin layer of this material over the ordinary concrete.

Lead Accumulators, Theory of. W. Löb. Zeits. für Elektrochem. 1896, 3, 100–101.

THE author criticises a theory of the lead secondary cell propounded by Professor Elbs. In electrolysis a solution of lead diacetate under certain definite conditions, Elbs succeeded in observing the formation of lead tetra-acetate, the acid residue which was left after the deposition of lead uniting with the salt present:—

The tetra acetate thus produced is decomposed by water, forming lead peroxide and acetic acid:—

Thus the tetra-acetate can only be obtained when no water is present; in aqueous solution all that is observed is a separation of lead peroxide. This Elbs regards as a secondary process, whereas Liebenow and Löb regard it as a primary phenomenon.

Elbs' theory requires that lead and lead peroxide should be produced in corresponding quantities in the cell. But this is not in accordance with experience; for, if we electrolyse with a large anode, by far the greater part of the lead present appears as lead peroxide. The fact that tetra-acetate is formed in the absence of water does not justify us in drawing conclusions as to the nature of the reactions which occur when water is present.—D. E. J.

Conversion of Nitriles into Amines by Electrolysis.

F. B. Ahrens. Zeits. für Elektrochem. 1896, 3, 99–100.

AN attempt to reduce nitriles electrolytically to amines, in accordance with the equation $\text{R.CN} + 2\text{H}_2 = \text{R.CH}_2\text{NH}_2$, which represents the usual mode of reduction by sodium amalgam or sodium and alcohol. It was found that in acid solution there occurred, together with the reduction of the nitrile, a saponification of it, with formation of acid, in accordance with the equation—

The lower the molecular weight of the nitrile the larger was the proportion of ammonia produced. Acetonitrile yielded only ammonia; propionitrile a fair proportion of *n*-propylamine, in addition to ammonia; and benzonitrile yielded only benzylamine. After electrolysis, the solution was treated with ether, to extract any unaltered nitrile; it was then made alkaline with soda, and the bases were driven off with steam. The distillate was neutralised with hydrochloric acid, evaporated down, and the salt extracted with absolute alcohol. Sal-ammoniac remained behind, while the hydrochloride of the amine went into solution, and was identified as chloro-platinate. Attempts to reduce nitriles electrolytically in alkaline solution were less successful, for practically nothing but ammonia was obtained.—D. E. J.

Electrodes for Voltaic Batteries, Impts. in the Manufacture of. [Alkaline Paste.] L. Epstein, Twickenham. Eng. Pat. 16,569, Sept. 4, 1895.

ELECTRODES rendered porous by the treatment described in Eng. Pat. 350, 1890 (this Journal, 1890, 812), or in any

other suitable manner, are coated with a paste formed of any of the oxides of lead in a saturated solution of caustic alkali, in such proportions that at least one-half the lead oxide is dissolved in the alkali. These plates are converted into negatives by connecting them to the negative pole of a source of electric supply whilst immersed in an electrolyte consisting of dilute sulphuric acid, or a solution of a suitable salt, such as a soluble sulphate or sulphite of an alkali or an earth. It is preferable to reduce all the plates first, and then to convert some of them into positives by drying them and connecting them to the positive source of supply; but the plates intended for positives may be first neutralised by dipping them in a bath of sulphuric acid, sulphurous acid, or other suitable solution, such as magnesium sulphate, drying them, repeating the process several times, and then forming them as before.—G. H. R.

Blanching Liquid, Impts. in the Electrolytical Manufacture of. [Cooling.] C. Kellner, Vienna, Austria. Eng. Pat. 17,525, Sept. 19, 1895.

See under VII., page 719.

Ozone, Impts. in Apparatus for the Production of. [Hollow Electrodes.] E. Andreoli, London. Eng. Pat. 10,372, May 14, 1896.

The ozoniser is connected at one end or at the bottom with an air-chamber provided with baffles, so that the air or gas to be treated is divided evenly between the electrodes, whilst at the top or at the other end is a receiver into which the gas passes as it is treated. There are two sets of electrodes, which are formed of shallow metal boxes, which may be provided externally with points, as in Eng. Pat. 17,426, 1891 (this Journal, 1893, 452). Water or other liquid is circulated through these hollow electrodes, so as to keep them cool, and they are so placed between the air and ozone chambers that no space is left on their active surfaces which is not in contact with the air forced into the apparatus.—G. H. R.

(B).—ELECTRO-METALLURGY.

Lead, Electrolytic Desilverisation of Argentiferous.
D. Tommasi. Comptes rend. 122, 1476—1477.

THE argentiferous lead is cast into suitable anodes; the cathodes are discs of a metal which is not attacked by the bath. The latter may be copper, aluminium bronze, or even sheet iron, but cast iron would precipitate metallic lead from the bath. The electrolyte is a double acetate of lead and sodium, or of lead and potassium. Under the action of the current, the lead is removed from the anodes and deposited in the form of spongy crystals upon the cathode; while the silver contained in the anode, being insoluble in the bath, falls into a perforated receiver at the bottom. The silver is washed, dried, fused in a crucible with sodium nitrate and a little borax, and cast into ingots. The fusion with sodium nitrate converts any antimony and arsenic (which may have been precipitated with the silver) into antimoniate and arsenate, whilst the silver remains in the metallic state. The lead is detached from the discs, washed, and submitted to great pressure. It is then fused in a crucible with two or three per cent. of carbon and cast into ingots.—D. E. J.

Mercury, Arsenic, and Antimony; Extraction from their Sulphides. L'Eclairage électrique, 1896, 276.

THE sulphides of these metals form double compounds with the sulphides and sulphhydrates of the alkaline earths. Upon this property is based the Siemens process for extracting from the sulphides, sulphur and the corresponding metal, without the formation of useless by-products. For example, when a solution of antimony sulphide in calcium sulphhydrate is electrolysed, antimony separates out at the cathode and calcium sulphide at the anode; no diaphragm is needed. By treatment with carbon dioxide in presence of water, the calcium sulphide is converted into sulphuretted hydrogen, calcium carbonate, and sulphur. When the mixture of the last two is heated in absence of air, sulphur and carbon dioxide are evolved. The

sulphur is condensed and the carbon dioxide is utilised for treating a further quantity of calcium sulphide. The lime which is left behind after the heating is converted into calcium sulphhydrate by the sulphuretted hydrogen obtained in the second operation.—D. E. J.

PATENTS.

Amalgams, Electrolytic Production of, and their Utilisation. E. Andreoli and S. W. Andreoli, London. Eng. Pat. 15,024, Aug. 9, 1895.

THE apparatus described consists of two vessels, termed respectively the electrolyser and the amalgamator, which are each divided into three compartments by means of two porous partitions. In the electrolyser the two outer compartments contain iron or copper anodes, whilst the centre division contains mercury, which forms the cathode; and in order to reduce the quantity of mercury, this division is nearly filled with a block of cement, so that the mercury takes the form of thin vertical films between it and the porous partitions, thus giving a very large surface for a small weight of the metal. The outer compartments are filled with chloride of sodium solution, and on the passage of the current, chlorine is liberated in them, whilst sodium amalgam is formed in the centre compartment, and is drawn off into the centre compartment of the amalgamator, the outer divisions of which are filled with a concentrated solution of sodium chloride, and connected to the positive pole of the source of electric supply, the centre compartment being meantime connected with the negative. Thus, while the copper or other metal is being amalgamated in the centre compartment, the strength of the amalgam is maintained. The amalgamator may be used dry, or the mercury amalgam may be covered with water. Various forms of the apparatus are described.—G. H. R.

Gold and Silver, Electro-Deposition of. [Lead Peroxide Anodes.] E. Andreoli, London. Eng. Pat. 16,557, Sept. 4, 1895.

THE difficulty of obtaining insoluble anodes for use in the electro-deposition of gold or silver from cyanide solutions, is overcome by the use of peroxide of lead, as described in Eng. Pat. 11,752, 1895 (this Journal, 1895, 810). The cathodes may be made of zinc or any other metal, and both electrodes are preferably perforated and arranged transversely in the electrolytic vessel, so that the electrolyte flows through them; but they may be solid, in which case they are placed longitudinally.—G. H. R.

Electric Smelting, Impts. in. [Alternating Currents.] T. L. Willson, New York, U.S.A. Eng. Pat. 17,063, Sept. 12, 1895. (Under Internat. Convention.)

THE furnace employed is preferably a Siemens furnace with a vertical carbon pencil, to which one terminal of an alternating current dynamo is connected, while the other is connected to the crucible or carbon hearth. In the production of aluminium bronze, powdered alumina and crushed carbon, together with copper in suitable proportion to form the required alloy, are fed into the furnace, where they are drawn into the arc by its pulsating action, which makes the feed continuous and automatic; or the copper or other base metal may be introduced first, so that it forms a molten layer on the hearth. The alternating-current furnace may be employed for various smelting and metallurgical purposes—among others, for the production of calcium carbide, described in Eng. Pat. 15,360, 1895 (this Journal, 1896, 5-2). A current of about 1,500 ampères at 55 volts, with 120 alternations per second, has been found to give good results, and it is stated that the output with an alternating current is nearly double that obtained with a direct current.—G. H. R.

Ferro-Manganese, Ferro-Chrome, Ferro-Aluminium, Ferro-Nickel, and other Alloys having an Iron Base; Impt. in the Electrolytic Manufacture of. [Carbon and Lime Flux.] J. Heibling, Grenoble, France. Eng. Pat. 18,487, Oct. 3, 1895.

THE furnace, which is partly cylindrical and partly conical is constructed inside of carbon and outside of fire-bricks

and has at its bottom a movable bed-plate, preferably formed of fusible cast-iron, which is intended to be melted during the operation. This bed-plate rests on another, also movable, which is formed of carbon bricks, produced by baking a suitable mixture of pulverised coke, plumbago, and tar in closed cast-iron moulds. This furnace acts as a negative electrode, the positive consisting of a bar of carbon, the size of which depends on the depth of the furnace and the electrical energy available. The powdered ore or oxide to be treated is mixed with a quantity of carbon equivalent to the oxygen in the ore, and as a flux, has incorporated with it a variable quantity of powdered quicklime, together with a further proportion of carbon. If the nature of the ore admits of it, an oxide of iron is added, together with a quantity of carbon necessary to effect its reduction, so as to obtain the required alloy, the weight of the cast-iron plate being taken into account. If the silicon present be in excess of the normal amount, powdered fluorspar is added. On the passage of the current, the ore and oxide of iron are reduced, and calcium carbide is formed by the mutual action of the calcium and carbon dissolved in the iron alloy. To remove the product, the carbon bed-plate is lowered on one side by suitable mechanism. The carbide of silicon present in the calcium carbide slag renders the latter more proof against the action of moist air than would otherwise be the case. An excess of silica is to be avoided.—G. H. R.

Sheets or Strips, or other Form of Metal, by Electro-Deposition, Improved Means to be employed in the Production of. [Cathode of Al or Al Alloy.] S. O. Cowper-Coles, London. Eng. Pat. 29,073, Oct. 21, 1895.

ALUMINIUM, or an alloy not containing less than 50 per cent. of that metal, is used for the construction of the cathodes, as it is stated that from such cathodes the deposited metal can be easily removed. The removal should be effected whilst the cathodes are wet, or, if they have been allowed to dry, they should be immersed in a weak alkaline or acid bath. The metal may be stripped from the cathodes in the form of sheets, or may be removed by rubbing, which method is preferred in the case of the deposition of gold. The cathodes may be of any suitable form, such as plates or continuous bands traversing the electrolyte, or of drums revolving therein.—G. H. R.

XII.—FATS, OILS, AND SOAP

Fatty Acids, Liberation of, by Pulverisation. Rev. de Chim. Industr. 7, [80], 237—239.

THE conversion of fats into free acids and glycerin is carried out by three different processes in the stearin industry:—(1.) Aqueous saponification in an autoclave under pressure. (2.) Saponification in an autoclave with the assistance of a base, such as lime or magnesia; and (3.) Lime saponification, completed by sulphuric acid, and subsequent distillation of the fatty acids. The first two have the advantage of yielding a more solid product, whilst the oleic acid and glycerin are in a more refined state. The last gives a higher yield of stearic acid, but the expenses of manufacture are greater and the commercial value of the products less. Hence the profits derived from the different methods are said to be about equal.

In Emile Petit's process the two bodies are brought together in the finest state of division, so that the sulphuric acid acts immediately on every particle. (See this Journal, 1895, 167.)

By this process the liberation of the fatty acids is complete and instantaneous, and a single turbine can produce from 30 to 40 kilos. per minute. The solid acids, which are but slightly coloured, are well cooled, and pressed in the cold to remove oleic acid.—C. A. M.

Hazel-Nut Oil. A. Schöttler. Apoth. Zeit. 11, 533—534.

The expressed oil (yield 50 to 55 per cent.) has a specific gravity of 0.916, at 15° C. It gave the following numbers:

Hübl's iodine value, 87; saponification value, 187; Hehner's number, 95.5; Reichert-Meissl's value, 0.99. The fatty acids solidified at 19—20° C. The saponification showed that the hazel-nut oil chiefly consisted of liquid glycerides, and only contained a very small quantity of palmitin, thus bearing a great resemblance to almond oil.—A. S.

PATENT.

Fish, Fish Offal, and the like, Impts. in or relating to the Treatment of [for Oil and Manure, &c.]. J. C. W. Staaley, London. Eng. Pat. 18,414, Oct. 2, 1895.

THE fish is boiled in a long, shallow tank, provided with a perforated plate near the top, and with a worm conveyor near the bottom. The fish is introduced by means of a hopper through an inlet near the bottom of the tank, and is gradually drawn by the conveyor into a second compartment, from which the solid matter is removed by means of buckets with perforated bottoms, attached to a chain. The material is subsequently treated as already recommended (this Journal, 1894, 165).

The oil rising to the surface of the water, through the perforated plate, overflows along with some water into a separate tank, from which the water is withdrawn from below, and re-delivered by pumping, to the cooking vessel; so that the same water is used over and over again. The oil is removed and purified by straining, or by filtering and washing, or by means of fuller's earth. The residue is used as manure, &c.—N. H. J. M.

PATENTS.

Lead Oxide [Air and Agitated Molten Lead], An Improved Method and Means of Producing. J. Noad, East Ham. Eng. Pat. 21,175, Nov. 8, 1895.

THE patentee describes an apparatus for the manufacture of lead oxide by the action of a blast of air on molten lead maintained in a state of violent agitation by suitable stirrers. The surface of the metal is covered with a thin layer of sand, and a spray of water is also introduced to assist in the operation. The oxide, "in a cloud-like, impalpable, floury condition," is blown over into a number of hoppers, and finally into a condensing chamber. It may be obtained in any desired colour, from a pale straw to a deep red, by regulating the temperature of the metal—the shade of the product becoming darker as the heat of the bath rises.

—F. H. L.

"White Lead," *Impts. [Ammonium Acetate Process in the Production of Basic Carbonate of Lead or]*. O. Hamilton, Northfleet, Kent. Eng. Pat. 22,460, Nov. 25, 1895.

This is an improved form of the regular "precipitation" process for the manufacture of white lead. The special improvements consist—(1) in the use of a 5 per cent. solution containing the acetates of lead and ammonium in molecular proportion, 9,000 galls. of which are capable of dissolving 35 to 40 cwt. of litharge; and (2) in the employment of "litharge (preferably made by oxidation of refined lead on bone-ash tests, as in cupellation of silver) which has been powdered in such a manner as to convert it into the red variety"—a form in which it is more soluble. Towards the end of the process, the liquid should be heated to 80° C., the oxide should only be added as fast as it dissolves, and the finished solution should have a gravity of 14° to 16° T. After carbonation the residual liquor should be about 4° or 5° T., and possess approximately the same composition as the original. The white lead is washed first with sodium carbonate to remove adhering acetate, and, after drying, it is passed under edge runners to roll out the air, thus rendering it more convenient to handle. The use of apparatus described in Eng. Pats. 11,243, 1892 (this Journal, 1893, 741), and 4,969, 1894, is recommended.—F. H. L.

White Lead, Impts. in the Manufacture of. W. P. and W. Tatham, Philadelphia, U.S.A. Eng. Pat. 13,886, June 23, 1896.

This is also a process for the manufacture of white lead by precipitation, the improvement here consisting in submitting the basic acetate to the action of the carbonic acid gas in a solid condition, whereby practically the whole of the litharge employed is converted into pigment and the proportion of "idle" lead is greatly reduced. The original solution should contain about 13 per cent. of lead acetate, and 2.25 times as much litharge should be added as the amount existing in the normal salt. This addition is made in two portions, about 60 per cent. of it being introduced without grinding in one vessel, the whole being then transferred to another, heated to 70° C., and the remaining 40 per cent. of oxide in fine powder stirred in until crystallisation begins. The resulting mass is treated with carbonic acid, and, after the white lead has been filtered off, the filtrate is ready to dissolve fresh litharge as before.—F. H. L.

(B.)—RESINS, VARNISHES.

Driers, Contributions to our Knowledge of. M. Weger. Zeits. für ang. Chem. 1896, 531—536.

SO-CALLED "soluble driers," the manganese and lead soaps of rosin, linoleic, oleic, and stearic acids, which for the last 10 years have gradually replaced materials like litharge, red lead, peroxide, hydrated oxide, and borate of manganese, possess also the advantage that they are perfectly soluble at comparatively low temperatures in linseed oil or turpentine. For the preparation of varnishes they can be added directly to the linseed oil at about 120° C., or dissolved in turpentine and mixed cold as "liquid driers" with the linseed oil. A considerable saving is effected in time, fuel, and labour, a boil-over or conflagration is entirely avoided, and in consequence of the low temperature a lighter varnish can be obtained. In spite of these advantages, however, the older methods were only gradually superseded, but at the present time the larger varnish factories in Germany and other countries employ almost exclusively soluble driers, which are in every respect superior to the old make. For the preparation of varnishes, driers should satisfy the following requirements:—1. The linseed oil must not be perceptibly darkened. 2. The driers must not cause either turbidity or deposit. 3. The linseed oil must dry quickly, certainly in 12 hours, generally in eight hours or less. Up to the present, driers only are known which satisfy two of the foregoing requirements. The author has carried out a number of experiments on the influence of various conditions or of the materials in the preparation of soluble driers. These are not yet complete, but in no case has a varnish been found which, after setting, has again become tacky. Driers containing lead occasionally lose their power, and this has also

been noticed in the lead-manganese linoleate, although manganese resinate does not show it. It has, however, been conclusively proved that with equal weights of metal a varnish which has been heated, does not dry more quickly than one prepared cold. Referring to recent papers by Amsel (this Journal, 1895, 605 and 814), the author points out, apart from certain criticisms as to the employment of soluble driers, that the question as to the suitability of a certain drier cannot be determined from a purely analytical standpoint. He considers that the saponification number for the ordinary kinds of rosin is about 170, for linseed oil about 190, and for linoleic acid, *i.e.*, the mixture of acids from linseed oil, about 198. Taking these numbers, 100 parts of resin would combine with 8.3 or 5.5 parts of manganese as a manganous or manganese salt, or with 31.4 parts of lead, which in percentages amount to 7.7, 5.3, and 24.0. For the corresponding salts of linoleic acid the percentages are 8.9, 6.1, and 26.9. According, however, to the method of preparation, the driers can contain manganese salts in different states of oxidation, or else basic salts, so that an empirical standard must be accepted. A soluble drier must contain its metal chemically combined with the organic acid, and not partially suspended as oxide. For the purpose of analysis, anhydrous ether is made use of, or in the case of lead resinate, chloroform. The solubility of the soaps in ether or chloroform is equal to that in linseed oil, so that anything insoluble in either of these two solvents in the cold, will be insoluble in warm linseed oil. Only lead and manganese compounds have drying properties, and the addition of zinc, copper, calcium, barium, or iron salts is of no value, although copper soaps are occasionally made use of for painting ships and as a rust preventative. The presence of uncombined oil is also prejudicial, and the larger the proportion of soluble lead or manganese the more valuable the sample, since less is required to be added to the oil to produce a varnish. Soluble lead driers alone are not employed, and only four compounds in general use are described more in detail, *i.e.*, the manganese and lead-manganese soaps of resin and of linoleic acid. "Fused manganese resinate" seldom contains more than 3.2 per cent. of soluble Mn, whilst precipitated manganous resinate only contains 6 or at most 7 per cent. Fused manganese linoleate contains 9—9.5 per cent., or in some cases nearly 11 per cent., probably owing to a decomposition or to the formation of a basic salt. Precipitated manganese linoleate is not a commercial article. With regard to the mixed soaps, the best proportion of lead to manganese appears to be 5:1, and the best samples show 8—9 per cent. of soluble lead, and 1.5—2 per cent. of soluble manganese. If larger quantities of soluble soaps be found, they are always accompanied by insoluble metallic compounds giving turbid varnishes. It is also possible for insoluble oxides and free resin or linoleic acid to exist side by side, and in most products this is the case. The following percentage of driers is required for the preparation of a good varnish, the amount of soluble metal being approximately that given above; fused manganese or lead-manganese resinate 2—3 per cent., precipitated manganese resinate 4—4½ per cent., and manganese linoleate 1 per cent. The addition is best made by dissolving 1 part of the driers in 2 parts of linseed oil at 120° C., and stirring this solution into the rest of the linseed oil. The latter can be heated before or subsequent to the addition of the driers for from 2—5 hours. A light varnish is obtained by the use of lead-manganese resinate, whilst fused manganese resinate gives one free from deposit. For the preparation of a varnish in the cold, fused manganese resinate, linoleate, or lead-manganese linoleate is dissolved in turpentine in the proportion of 1:2 or 2:3. As regards the analytical determinations, after burning off the organic matter, the lead and manganese can be estimated, the latter volumetrically. If calcium be present in any quantity, after removing the lead, the manganese and calcium are determined gravimetrically as carbonate, and the manganese having been estimated as above, the calcium is found by difference. The total lead and manganese having been found, the insoluble portion is determined by extraction with ether or chloroform. The soluble manganese is determined from the difference, and can be confirmed by determination in an aliquot part of the ethereal extract.

The soluble lead can only be determined from the difference, since chloroform is only driven off completely from the rosin solution at a red heat when the greater part of the lead as chloride volatilises also.—T. A. L.

Linseed Oil for Varnish-making, Possibility of Using Chloride of Sulphur for thickening. Chem. Revue Fett-u. Harz Ind. 3, [44], 147—149.

It is proposed to treat linseed oil for varnish in a parallel manner to that pursued in the production of caoutchouc substitutes, *viz.*, by the action of warm chloride of sulphur. The intensity of this reaction varies with the kind of oil chosen, 20 per cent. of chloride of sulphur sufficing to solidify castor oil, whereas linseed oil requires 30 per cent., but when the oil has been oxidised about one-half the quantity will produce the same result. To produce a consistency suitable for lacquer less than 20 per cent. is required for raw linseed oil and not over 7 to 8 per cent. when the oil has been oxidised.

Provided the oil and reagent are carefully and rapidly mixed to prevent partial clotting, the operation is easy. In drying properties the product is not superior to boiled oil of the same consistency, but this may be improved by the addition of manganese sesquioxide to the finished varnish. Whether this addition will affect the durability, &c. of the varnish will have to be determined by experiments on a large scale.

According to Heinzerling, a solution of camphor in chloride of sulphur acts more effectively on oil than the latter reagent alone, but the high price of the former is prohibitory.—C. S.

Coloured Lacquer by Dipping, Process for Coating Metal, Bone, or Celluloid Articles with. J. Perl. French Pat. 233,727, Oct. 30, 1893. Chem. Rev. 1896, [42], 127.

HITHERTO the production of a satisfactory coating of coloured celluloid lacquers has been rendered difficult by the tendency of the lacquer to accumulate in the hollows of the ornamentation of the article, thus giving rise to irregularities of colour, and, moreover, the dyes employed lacked transparency and stability, fading when exposed to light.

These difficulties are overcome by the new process, which consists in applying a colourless covering of lacquer, and after drying for about half an hour at 60° C., heating the article strongly and dipping it in a solution of aniline or alizarin colours in strong alcohols (ethyl, methyl, or amyl alcohol). The amount of colour for the bath does not exceed $\frac{1}{10}$ to $\frac{1}{4}$ per cent., or about one-fifteenth the quantity of the transparent lacquers now in use. A brilliant permanent gold colour may be produced on copper by a bath containing 1 gram. of alizarin per litre. Darker colours may be made by adding a small quantity of an alkali soluble in alcohol to the bath.

The essential points to ensure success are perfect dryness of the article, which must also be well warmed and thoroughly clean; and the absence of all oily or fatty materials in the bath.—C. S.

PATENT.

[*Waterproof Varnish*], *Rendering Articles Waterproof or Airtight, or as a Cement or Varnish, or for other similar Purposes; New or Improved Compound applicable for.* A. Pulbrook, London. Eng. Pat. 14,839, Aug. 6, 1895.

THIS consists of a mixture of balata, or any other gum derived from the trees of the order Sapotaceæ except gutta percha, and indiarubber dissolved in equal proportions in any suitable volatile solvent or mixture of solvents. It may be applied by dipping or with a brush; and as a waterproofing varnish it is claimed to possess the advantages of vulcanised rubber as regards permanence, without the injurious action of the sulphur used in the preparation of that material.—F. XIV.—TANNING, LEATHER, GLUE, SIZE.

Tanning Extracts, Manufacture and Valuation of.

F. Jean. Rev. Chim. Ind. 1896, 7, 269—271.

THE manufacture of tanning extracts now closely resembles the process for extracting sugar; the sliced wood is exhausted by diffusion in autoclaves under slight pressure, and the liquor is filter-pressed and evaporated in triple-effect apparatus which differ from those used at the sugar-works merely in being constructed entirely of copper and bronze, to the exclusion of iron, and in being worked at a higher vacuum than sugar-pans are. Most manufacturers decolorise the liquor before concentration, either by the addition of some metallic salt, or with albumin and bisulphite of soda; in the former case the acid of the salt remains in the extract, and in the latter sulphate of soda and non-coagulable albuminoids are retained, whilst in both cases tannin is necessarily precipitated. The presence of salts in tanning extracts is much to be deprecated, since they accumulate in the tan pits to the detriment of the leather.

Roy has shown that the so-called "decolorising processes" are beneficial to the extract, not because they eliminate colouring matters, for they do this in a very minor degree, the colour of the liquor after treatment being but slightly diminished if estimated on the basis of equality of tannin-content—but because they precipitate, together with the first portions of tannin, certain earthy and metallic bases, such as lime, magnesia, manganese, iron, and copper, derived from the wood and from the apparatus; it is these foreign matters which are taken up, combined with tannin, by the leather, imparting bad colour and harsh and brittle grain. By substituting an aqueous solution of potassium ferrocyanide for the precipitants previously used, Roy has succeeded in removing these metallic compounds without appreciably decolorising the extract, and finds that the leather produced by the treated extract is in every way comparable with that prepared with oak bark liquor made in the tan-yard.

It follows that tanning extracts must be examined for salts of the alkalis and alkaline earths, and for metallic compounds, and valued in accordance with their content of these, as well as with their content of tannin.—A. G. B.

Glue Making Industry in Germany. R. Kissling.

Chem. Zeit. 1896, 20, [72], 697.

DURING the past year manufacturers of leather glue have been very busy, and the price of their product has risen some 10 or 15 per cent. On the other hand bone glues have fallen in value, and most of the makers have been working at a loss.

Among new processes, Grillo and Schröder of Neumühl-Hamborn, have patented the use of liquid sulphurous acid to convert the tribasic phosphate of bones into the dibasic salt (citrate-soluble), with the object of rendering the material brittle, more easy to powder, and more completely acted upon by boiling water. Sulphurous acid, however, is not a convenient reagent to employ on the manufacturing scale; and it would involve considerable change in the extraction apparatus. German patents have also been taken out for allowing the finished glue solution to run on to cooled revolving cylinders; thus yielding endless bands of the substance, which may be brought up to the desired thickness afterwards by compressing two or more together.

As regards methods for the valuation of glue, Fahrion's saponification process, according to which the sample is split up into unsaponifiable matter, fatty acids, liquid and solid oxyacids, &c., by means of petroleum ether, may possibly throw some light on the constitution of gelatin; but it is not adapted for commercial work. Tests based on the consistency of the glue jelly are very difficult to carry out, and cannot be considered satisfactory; although the author's suggestion of determining the viscosity, after the manner of a lubricating grease, may perhaps lead to better results. A mixture of 1 part of glue and 3 of water should be examined at a temperature of 20° C. The amount of water any sample of glue will absorb is no criterion of its cohesive power.

The author holds that the odour of glue is one of the most important factors to be taken into consideration. In order to express this in figures, six different standard samples should be rasped to powder, and preserved in well stoppered bottles, for they will be found to preserve their characteristic smell unchanged for years. The colour of the specimen under examination may also be classed in a similar manner. To estimate the fat, 20 grms. of the glue are dissolved in a 200 c.c. cylinder in 140 c.c. of water and 10 c.c. of 1.19 hydrochloric acid. After heating three or four hours on the water-bath under an inverted condenser, the solution is cooled, 50 c.c. of petroleum ether added, the whole well shaken, and after standing till clear, a portion of the solvent is drawn off, and evaporated in the usual manner. Free and combined volatile acids may be determined, and sulphurous acid tested for by distillation in an atmosphere of hydrogen as previously described (Chem. Zeit. 1887, **11**, 691; this Journal 1887, 565—566).—F. H. L.

PATENTS.

Tanning, and Apparatus for that Purpose, Impts. in. E. Worms, Paris, France. Eng. Pat. 19,428, Oct. 16, 1895.

THE object of the invention is to hasten the tanning process by gradually and moderately heating the hides and the liquor within a closed vessel excluding air, and at the same time "expelling the water from the cells of the hides by electrically decomposing it." The hides are submerged in water in a rotating drum, and a tannin extract of 20 B is run in, in the proportion of 50 per cent. of the weight of the hides, together with a "vegetable solvent" amounting to "5 per cent. of such weight." The drum is closed and rotated. When the temperature has risen to 15° C., an electric current is passed through the liquor by means of a suitable circuit, the temperature being maintained by its means at 25°—30° C. When the process is half completed the circuit is broken and fresh tannin is introduced. Light hides are tanned in 24—48 hours, heavy hides in 60—105 hours.—A. G. B.

Artificial Fur [Beaver and Nutria], Impts. relating to the Manufacture of. J. Biermann, Berlin, Germany. Eng. Pat. 4062, Feb. 22, 1896.

LAMB skins are placed in a soap and water bath and then pressed out and brushed with a colour solution prepared by dissolving 1 part by weight of ursoil D (paraphenylenediamine), 2 parts by weight of ursoil P (paramidophenol), 1 part by weight of pyrogallol, 50 parts by weight of hydrogen dioxide, and 4 parts of ammonia in hot water and diluting to the desired tint with cold water. After drying, the hair of the skin is combed with a wire comb, and a silky gloss is produced by ironing with acid. Beaver and nutria imitations are thus prepared.—A. G. B.

Hides and Skins, Treating [with Carbonic Acid], for the Purpose of Removing Lime and other Undesirable Matters therefrom, and Preparing the Hides and Skins for being Immersed in or otherwise Treated by Tannin; An Improved Method for.—J. A. McIntosh, Newcastle-on-Tyne. Eng. Pat. 5644, Mar. 13, 1896.

After the hides and skins have been taken from the lime pits, they are suspended in an hermetically sealed receptacle into which is injected water containing carbonic acid under a pressure of about 30 lb. per square inch. The lime is thus removed and the skins are brought to a condition in which they can be quickly tanned.—A. G. B.

Leather [Tanning], Impts. in and Relating to the Manufacture of. F. E. Burlingame, Central Falls, Providence, Rhode Island, U.S.A. Eng. Pat. 15,044, July 7, 1896.

THE prepared hides are immersed in a bath containing "the liquid product of the destructive distillation of wood" and common salt, or other salt of the alkalis or alkaline earths. When the liquor has sufficiently penetrated the hides, they are partially dried and immersed in a saturated solution of common salt for from 1—10 hours; washing and the usual finishing process complete the manufacture.—A. G. B.

Chemical Manure Mixers and the like [Revolving, Corrugated Cylinder], Impts. in. E. Pater-Notte, Hammelmille, Belgium. Eng. Pat. 15,473, July 13, 1896.

THE apparatus consists of a cylinder, lined with corrugated iron to prevent the slipping of the substances to be mixed, and revolving on a fixed axis. Inside is a beater which consists of an axle, traversed by dash-boards, turning at the ends of rods fitted into the axis on which the cylinder turns. The beater is turned by means of a chain passing over a wheel fixed to the cylinder. The cylinder is provided with sliding doors for introducing the substances to be disintegrated, or mixed, and for emptying the apparatus. The beater can be turned into any desired position, and be fixed at any distance from the wall of the cylinder, according to the amount of substance to be mixed. As the cylinder turns, the substances are drawn to the height of the beater where they revolve and fall on the dash-boards, the motion of which is very rapid and in proportion to the rate at which the cylinder rotates.—N. H. J. M.

XVI.—SUGAR, STARCH, GUM, Etc.

Sugar Cane, Carbohydrates of the. H. C. Prinsen-Geerligs. Chem. Zeit. 1896, 20, 721.

THE author concludes, from data furnished by optical and reducing powers before and after inversion, that the ratio between saccharose, dextrose, and levulose in the leaves from the unripe sugar-cane is 1:2:4. In the upper portion of unripe canes of six months' growth, the ratio was 1:1:1; three months later it became 3:2:1, whilst in the lower parts of canes nine months old the ratio found was 82.5:3:1. These figures show that the levulose diminishes as the cane ripens. This is borne out by the observations of Willey, who found levulose in the juice from ripe Louisiana canes, whilst Winter demonstrated its absence in canes grown in Java, the warmer climate of the latter place probably inducing a greater degree of ripeness in the cane.—J. L. B.

Ammonia, Impts. in or relating to the Production of, from Waste Nitrogenous Lyes or Gases [From Sugar or Molasses Spirit]. H. H. Lake, London. From L. Sternberg, Jersey, New Jersey, U.S.A. Eng. Pat. 7002, March 31, 1896.

See under VII., page 720.

XVII.—BREWING, WINES, SPIRITS, Etc.

Unfermented Wine. Müller. Apotheker Zeit. 11, 724.

The author has applied the principle of Pasteur's treatment of wine for the preservation of grape juice and other fruit juices without fermentation. He finds that when the freshly-expressed juice is heated in bottles to a temperature of 60–70 °C. for 15 minutes, the yeast cells and other fermenting agents are rendered inactive. The juice can then be kept in well-closed bottles for several years without fermenting. To obtain the juice clear, it must, however, be filtered, an operation which is easily carried out, as the heating will have coagulated the mucilaginous substances causing turbidity. Filtration may be carried out immediately after heating the juice, or after some time, but in any case, the filtered juice must be again heated in bottles to the same temperature originally applied.—A. S.

Barley, Colour of. Schonfeld. Wochenschr. für Branerei, 13, 1896, 966.

It is pointed out that in buying barley too much stress is often laid on lightness of colour of the corn. Rain often causes darkening in colour without materially affecting the value of the grain for brewing purposes. A thin and somewhat crinkled skin and a full and not too hard corn should be sought for.—L. T. T.

Invert Sugar. J. Heron. J. Fed. Inst. of Brewing, 1896, 2, 440–452.

THE author proposes the following scheme for the analysis of commercial invert sugar: (a.) The invert sugar is determined gravimetrically according to O'Sullivan's directions (J. Chem. Soc. 1876, 2, 130). (b.) The amount of cane-sugar, by determining, gravimetrically, the total reducing sugar after inversion, by means of Fehling's solution; from this the amount of reducing sugar, similarly determined before inversion, is subtracted, and the remainder multiplied by 0.95. (c.) The quantity of other carbohydrates is found by subtracting the sum of invert sugar and cane-sugar from the true amount of carbohydrates in solution, the specific gravity of the solution being corrected for the gravity due to ash before dividing by the 3.86 factor. (d.) The sulphated ash is considered to represent the percentage of mineral salts in the sample under examination. (e.) Owing to the decomposition of levulose when heated in the air or water-oven, the moisture is determined by difference.

—J. L. B.

d-Galactose, Fermentability of. A. Bau. Zeits. f. Spiritusinst. 19, 1896, 303–305 and 312.

As the statements of different workers as to the fermentability of galactose are so divergent, the author has carefully re-investigated the matter. The results of his researches definitely prove that *d*-galactose is fermentable under suitable conditions and with certain ferments, but is not as readily so as many of the other sugars.

The researches of himself and others may be summed up as follows:—

1. *d*-Galactose is not fermentable by *S. productivus*, *S. membranifaciens*, *S. apiculatus*, and *Schizosaccharomyces Pombe*. It is completely fermentable by *S. cerevisia*—both top and bottom forms of Saaz and Froberg types—by *S. Logos*, *S. Pastorianus* I., II., and III., *S. ellipsoideus* I. and II., *S. Marxianus*, milk-sugar yeast, and *Monilia candida*. As in other sugars and dextrinous solutions, *M. candida* only produces very sluggish fermentations.

2. *d*-Galactose is fermentable with more difficulty than *d*-glucose (dextrose), but it is still uncertain whether it is less readily fermentable than levulose. It is also still doubtful whether top-culture *S. cerevisia* is more active in its ferment action on galactose than bottom-culture yeast.

3. For the free fermentation of galactose it is necessary for the yeast to be in a healthy condition, and for suitable nutriment to be present.

Galactose does not seem to occur free in nature or in the materials generally used by the brewer. But in molasses it is often present, and, therefore, in spirit manufacture and yeast production, where molasses are employed, a know-

ledge of its action towards ferments is important, in order that it may be utilised for the production of alcohol and the formation of yeast cells.—L. T. T.

Isomaltose. H. Ost. Chem. Zeit. 1896, 20, 761–762.

THE author previously stated (this Journal, 1895, 877) that the disaccharide obtained by the action of acids on glucose yielded an osazone, which he believed to be maltosazone; this, however, is not the case, Fischer (*ibid.* 1896, 43), having shown that his isomaltose is unfermentable.

According to a method proposed by the author, isomaltose is now prepared by the action of 33 per cent. of sulphuric acid on glucose or maltose, for 4½ months, at the ordinary temperature. About 30 per cent. of an unfermentable product results, which is identical with isomaltose. It can be obtained only in the form of a slightly sweet syrup, having a specific rotatory power of $[\alpha]_D^{20} = +70$, and a reducing power ½ that of maltose. It forms an osazone soluble in water, but is most conveniently crystallised from 60 per cent. alcohol, from which it separates in yellow aggregates of needles, which melt at 130–145°, and have a specific rotation in Auer light of $[\alpha]_{\text{Auer}} = -20$.—J. L. B.

Di- and Polysaccharides, Action of Alkalis on the Phenyl-osazones of. C. J. Lintner. Chem. Zeit. 1896, 20, 763.

WHEN aqueous solutions of the osazones of maltose, galactose, melibiose, and one of the achroo-dextrins, but not glucose, are boiled with caustic soda or potash, glyoxalosazone separates in small crystals. The result is not affected by an excess or otherwise of alkali. The glyoxalosazone may be purified by repeated crystallisation from hot alcohol, or by precipitating a solution in ether or benzene with ligroin (petroleum spirit). It separates either as light yellow plates or deep yellow prisms, the latter being the more soluble. When heated in an alcoholic solution with fuming hydrochloric acid, both modifications yield a yellowish-red, crystalline hydrochloride.—J. L. B.

Yeast, Influence of Oxygen on Fermenting. R. Rapp. Ber. 1896, 29, 1983–1985.

According to Chudiakow (this Journal, 1895, 14, 290), a current of air passed through a solution of sugar in process of fermentation, has a retarding influence on the action of the yeast, and will in fact nearly stop the fermentation in the course of a few hours. On the other hand, hydrogen passed through in proportion to the carbon dioxide produced, is almost without action. The author has repeated these experiments under similar conditions, but with greater refinements, and he finds that suppression of fermentation does not result, as stated by Chudiakow. If, however, the quantity of yeast present be considerable, and the rapidity of the air current be increased to from 4–5 l. per hour, fermentation is certainly retarded, but under similar conditions hydrogen will produce the same effect. This result is in fact to be attributed, not to the chemical nature of the gas employed, but to the mechanical action of the current. In fact, it is shown that vigorous agitation alone will reduce the fermentative action of yeast to a minimum. The author contends, therefore, that whilst oxygen is necessary for the multiplication of yeast, it is without influence on fermentation, but that under certain conditions the latter process may be checked by agitation.—A. K. M.

Hops. L. Briant and C. S. Meacham. J. Fed. Inst. of Brewing, 1896, 2, 408–440.

THE authors show that the resins in hops, after being stored in cylinders for three years, remain practically unchanged in spite of the objectionable odour which the hops develop, and that a low temperature preserves hops quite as effectually as storage in an atmosphere of carbon dioxide. The peculiar odour in stored hops is due to the alteration of the oils, which takes place either in the presence or absence of air, although the minimum effect was observed at low temperatures. In order to study the effect of such low temperatures upon the preservation of hops, portions of the same sample were introduced into stoppered bottles, and, judging from the results of the estimation of the resins, the

authors consider a temperature of 38°—40° F. to be the most favourable. Experiments are described showing that the preservative value of hops is due to the percentage of resins which they contain. Brewings were carried out with disoiled and ordinary hops, and the results obtained demonstrate that in disoiling hops the soft are partially converted into hard resins, that these undergo a further rapid deteriorative change, and that oil of hops does not possess preservative power.

The influence upon the value of hops, of climate, ripeness, soil, drying, and general manipulation are also dealt with.

—J. L. B.

Malt and Wort, Acidity of. H. Johnson. Bull. Assoc. Belge des Chimistes, 10, [4], 162—172.

THE author's experiments confirm Fernbach's observations (this Journal, 1896, 621), to the effect that organic acids may combine with neutral phosphates to form acid salts.

Referring to the acidity produced at certain temperatures in the brewing process, he finds that the percentage of acid in the wort increases with the temperature of the mash between 40° and 60° C., but is lessened if a higher temperature (70° C.) be maintained, the production of acidity in the wort ceasing at 65° C. The influence of added acid (acid wort or sour milk) and the effect of temperature on its action was also studied, with the result that at 40° C. the lactic ferments were found to exert an appreciable influence on the degree of acidity, but at 50° and 60° C. this action was no longer apparent.

In a final series of experiments the effects of alcohol and chloroform in retarding acidity formed the subject of investigation. From the results obtained it appears that only in the case of acidity due to added acid ferments can these two substances be said to exert such influence to any appreciable extent. From this circumstance it is considered that the acidity cannot be due to lactic acid, an opinion strengthened by the fact that 50° C. is the most favourable temperature for the development of the acidity observed, this temperature being an impossible one for the production of lactic acid. On account of the limits of temperature referred to it is evident that the action is not purely one of extraction, but rather chemical, and restricted to temperatures below 65° C. The conditions point to diastatic action, and, since starch products are out of the question, indicate acid bodies formed by the action of peptase on nitrogenous substances, *i.e.*, bodies similar in their characteristics to asparagin and aspartic acid. It is also considered probable that the increase in the acidity of the contents of the grain of barley during germination, may be due to the same action.

—C. S.

Wines, Preparation and Treatment of Fruit Wines.

J. Nessler. Zeits. für Spiritusind. 1896, 19, [37], 297.

IN fruit-musts the proportion of acid to sugar is generally excessive and the resulting wine will consequently be poor in alcohol, rich in acid, and therefore of inferior taste and stability. These defects may be overcome by the addition of sugar to the must, the amount required depending upon the acidity of the must and the character of the wine it is intended to produce. There may also be a deficiency of yeast food, resulting in a slow fermentation and difficult clarification, and these defects may be obviated by the addition of ammonium chloride to the must (20 grms. to the hectolitre). The fermentation should be carried out quickly and the yeast separated as soon as possible. Sometimes the number of yeast cells present on the fruit is very small, and in such cases it is advisable to add some pressed yeast. The temperature during fermentation is also of importance, and should be about 15°—19°. Acetic fermentation has, of course, to be very carefully guarded against. In order to ascertain if a wine will readily clarify, a portion is shaken to remove carbon dioxide, and allowed to stand in a bottle in which the rate of clarification can be observed. If it remain cloudy, clarification may be effected by means of fresh wine yeast or kaolin. Red wines require very careful treatment on account of the readiness with which the colouring matter becomes removed or destroyed. In the transport of wines, the temperature should not be allowed to fall below 4°, or the wine is apt to become cloudy,

and in the case of red wines the colour becomes paler or sometimes even brown. If wine becomes discoloured through contact with iron, clarification with wine yeast or with milk (one teaspoonfull to the bottle) is recommended.—A. K. M.

Wine, A Green-coloured Secondary ("Nachwein").

A. Borntraeger. Chem. Zeit. 1896, 20, 686—687.

THE green colour of a sample of wine submitted to the author is attributed to the action of ferric iron on anotannin (wine-tannin). The colour may be removed by the addition of gelatin, which throws down a dirty-green precipitate, the filtrate from which is faintly yellow in colour and contains about half as much iron as was originally present.

—A. K. M.

Alcohol, Denaturing. [French Legislation.] Rev. Chim. Ind. 1896, 7, 277—279.

JACQUEMIN has proposed to denature alcohol to be used for lighting purposes by the addition of "trihydrated ethyl hydrosulphide," obtained by distilling a mixture of solution of barium ethyl sulphate and barium sulphide; 5 grms. (costing 15 centimes) per hectolitre of alcohol of 90° is sufficient, the amount of sulphur thus introduced being negligible. Leroy has calculated that alcohol could not replace petroleum for heating purposes unless its price fell to 22 fr. 50, that of petroleum being 50 fr.

The following decisions in respect of denaturing alcohol have been made by a French committee. (1.) *Varnishes and colours for varnishes.*—Mix 15 litres of methylene with 100 litres (at 15°) of alcohol of 90° and upwards. (2.) *Lighting and manufacture of varnishes.*—Mix 15 per cent. of methylene and 4 per cent. at least of resin with alcohol of 90° or upwards. (3.) *Hat-making.*—Mix 15 per cent. of regulation wood spirit with the alcohol. (4.) *Insecticides.*—Mix 15 per cent. of methylene with the alcohol. (5.) *Ethers, simple or compound.*—The alcohol is mixed with 10 per cent. of its volume of the residue of ether already defined by the committee; the mixture must have the evil odour of the added matter, and must become opalescent when diluted with water; 10 or 20 per cent. of sulphuric acid, according to the application of the alcohol, is then added, following the prescription previously laid down.

The alcohol used for making ethyl bromide, iodide and chloride, alcoholic soda, aldehyde, chloral and collodion is to be mixed, under due supervision, with the reagents by which it is treated in the course of conversion into the product of the works.

(6.) *Dyes.*—Mix the alcohol with 14 per cent. of its volume of methylene. (7.) *Tannin and alkaloids.*—Add 15 per cent. by volume of methylene. (8.) *Mercuric fulminate.*—Mix the alcohol with 15 per cent. of its volume of regulation wood spirit, or add to the alcohol the residues of the previous batch of fulminate. (9.) *Lighting and heating.*—To 100 litres of alcohol (90°) add (a) 15 litres of methylene, (b) 0.5 litre of heavy benzine (b.p. 150°—200°), and (c) 1 gm. of malachite green. (10.) *Transparent soap.*—Add to the alcohol 15 per cent. of regulation wood spirit. (11.) *Chloroform.*—Dealt with in previous reports. (12.) *Pressure liquid.*—The alcohol is sufficiently denatured by the salt water with which it is diluted provided the alcoholic strength of the mixture does not exceed 10°. In the absence of these conditions 15 per cent. of methylene must be added.

In nearly all cases where denaturing with wood spirit or methylene is allowed it is provided that the mixture shall be made at the works and not removed outside.—A. G. B.

Fermenting Vats or Vessels [Beer], An Improved Apparatus for Discharging Liquids from. X. Reischböck, Cüstrin, Germany. Eng. Pat. 20,933, Nov. 5, 1895.

THE apparatus consists of three parts:—A cylindrical tube which is inserted vertically in the bottom of the vessel; a cylindrical plug which fits into this tube and having the lower portion perforated, the perforations communicating with the interior of the plug, which is open below and closed above, and is capable of sliding in the casing tube; the third portion is a tap which screws on the lower end of the fixed tube and in doing so slides up inside this tube and presses the plug up so as to bring the perforations into communication with the contents of the vessel. Thus, when the tap is opened, the contents may be run off and are at the same time filtered by the perforated plug.

Beer and other Liquids containing Carbonic Acid, New or Improved Process and Apparatus for Increasing the Stability of. [Pasteurising.] H. Gronwald, Berlin, Germany. Eng. Pat. 9923, May 9, 1896.

THE apparatus consists of a boiler provided with a steam jacket, a filter, and receivers for the treated beer.

The apparatus is prepared for use by sterilising with steam, and then filling with sterile carbonic acid gas. The beer is then run into the boiler and heated to the required temperature, the gases which are given off being collected; the beer on being cooled re-absorbs these gases, is filtered, and collected in the receiving vessels.—A. L. S.

Filtration of Liquids, Impts. in. W. J. and C. J. Lomax, Bolton, Lancaster. Eng. Pat. 16,693, Sept. 6, 1895.

THE inventors describe an apparatus they call a "breathing" filter, in which the liquid during its passage is made to force air backwards and forwards through the filtering material. The filter bed is composed of layers of any suitable material, such as sand and polarite, and is preferably circular in form. The water or sewage to be filtered is admitted to a central tank, from which it is periodically flushed over the surface of the filter bed and percolates into a closed tank or chamber beneath. The displaced air from this tank is driven upwards through the filter bed, and when the tank is full enough it suddenly empties itself by siphon action, and in so doing aspirates fresh air through the filter bed in a reverse direction.—L. A.

Plates, Bricks, and Pipes for Filtering and like Purposes; Impts. in the Manufacture of Porous, Hard, and Acid-Resisting. W. Schuker, Isny, Württemberg, Germany. Eng. Pat. 18,573, Oct. 4, 1895.

Purification of Drinking Water [Liming, Subsequently Neutralising], Impts. in or relating to Processes and Apparatus for. H. J. N. Berge, Brussels. Eng. Pat. 19,360, Oct. 15, 1895.

IMPROVEMENTS in the method of purifying water by treatment with lime, followed by neutralisation of the excess of lime, are described. The water and the milk of lime are caused to flow in proportioned streams through a cone, whereby an intimate and very thorough mixture is claimed. If carbon dioxide be used for neutralisation, it is drawn into the water by causing the latter to flow through a kind of water-jet aspirator connected with the carbon dioxide producer. Instead of carbon dioxide, a solution of iron may be used for neutralisation.—L. A.

Purifying Water [Scrap Iron and Aëration], Impts. in Apparatus for. W. G. Waterman, London. From L. Alers-Hankey, New York, U.S.A. Eng. Pat. 15,611, July 14, 1896.

APPARATUS for purifying water by means of scrap iron is claimed; it has for its object efficient and economic means for aerating the water, for securing better contact of the iron with the water, and general simplification of such systems. The iron, in the form of borings or turnings, is contained in a series of boxes fixed round the periphery of a wheel or drum which slowly revolves in the water. Each box is perforated on one side only, and is fixed in such a position that the perforated side first meets the water when the wheel is rotating. The air imprisoned in the box is thus carried down to the bottom of the tank during the first half-revolution of the drum, but during the second half the perforated side of the box is turned up, causing the air to escape in bubbles and become replaced by water, which is emptied out again as the box passes over the top of the wheel. The friction, caused by the continual shifting of the iron in the boxes, keeps the metallic surfaces clean and thus in an active condition.—L. A.

Treatment of Sewage and other Liquids, Impts. in Apparatus for. E. W. Ives, Derby. Eng. Pat. 16,034, July 20, 1896.

IMPROVEMENTS are referred to in apparatus described in Eng. Pats. 13,411 of 1893 (this Journal, 1894, 832), 16,724 of 1894, 20,744 of 1894 (this Journal, 1895, 178), and 22,545 of 1895.

THE sewage flows first into a combined chemical chamber, detritus snuff, and storm overflow; thence into a circular screening chamber, where the suspended solids are broken up, and finally into the precipitation tank, constructed as described in the previous patents. If the effluent from this tank be not clear enough, the outlet valve is closed, causing the water to rise through a filter bed in the upper part of the tank. This filter bed is arranged round a

central short vertical cylinder, open top and bottom, and projecting above and below the filter bed. When the rising water reaches the lower edge of the cylinder, the air in the annular space between cylinder and tank walls, is trapped and forced upwards through the filter; and when the water-level is lowered again by opening the tank outlet valve, fresh air is admitted below the filter through the open cylinder.—L. A.

(C).—DISINFECTANTS.

Corrosive Sublimate Dust [Germicide]. Efficiency of.
P. Chavigny. Ann. Inst. Pasteur, 10, 351—357.

THE author made experiments to ascertain how the disinfecting power of the finely-powdered mercuric chloride compared with that of sublimate dissolved in common salt solution and in hydrochloric acid. The experiments showed that sprinkling with sublimate was not sufficient to destroy germs of micro-organisms, but only weakened their virulence. The protection which the sprinkling afforded against bacteria, was a limited one, and was done away with if the protecting antiseptic layer were removed and communication between the protoplasm and the surrounding medium restored.—A. S.

"Formalin" (Formaldehyde), Disinfecting Power of.
H. Strehl. Centr. Bl. f. Bakter. u. Parasitenk. 19, [1], 785—787.

THE author experimented with formalin vapour. He used, in one case, a trunk of $\frac{1}{2}$ cb. m. capacity, with a wooden grating placed 15—30 cm. above the bottom, on which grating were spread out layers of cloth. As objects of experiment, the spores of cattle distemper (anthrax) and staphylococci dried on silken threads were used; they were partly hung free in the chest in finely-netted, small wire baskets and partly wrapped in sterilised paper and put in the pockets of the dress-pieces used in the experiment. The formalin was sprayed into the trunk by means of a suitable apparatus; or filter paper saturated with formalin was placed under and between the layers of cloth; or the cloth impregnated with infected threads was wrapped up with cloth sprinkled with formalin. The cloth remained from 24 hours to 3 days in the trunk. It was found that 50 c.c. of pure formalin was not sufficient to destroy the bacteria in the closed trunk—a statement not in accord with the experiments of Lehmann, Stahl, Oelmichen, &c.

Experiments were also made on the sterilisation of smooth, rough, and velvet carpets, by means of formalin. Virulent broth cultures of staphylococci and anthrax bacillus were well rubbed into the sterilised pieces, and, after drying, they were hung free and sprayed with formalin solutions of different strengths until they were equally damp all over. After using a 5 per cent. formalin solution, the cultures of staphylococci still exhibited growth, a 10 per cent. solution sufficing to destroy all bacteria.

It appears therefore that formalin vapour is only in a small degree, capable of destroying bacterial life in dried

material; on the other hand, a direct contact of the formalin solution with the bacteria appears to be necessary, in order to cause satisfactory disinfectant effect.—A. S.

Formaldehyde as a Disinfectant. E. Schepilewsky. Centr. Bl. für Bakter. und Parasitenk. 19, [1], 794—796.

THE author experimented with a view of establishing (1) the influence of formaldehyde in solution and in the form of vapour on different kinds of vegetative bacteria (baceilli of cholera, typhus, staphylococci, pyog. aureus) and on the spores of cattle distemper (inflammation of the spleen), and the saprophytic bacteria occurring in sheep skins, which are capable of great resistance; (2) its influence in the form of vapour on the bacteria occurring in their natural conditions; (3) its influence on fabrics, furs, metals, and dyed stuffs; (4) the most advantageous method of using formaldehyde for disinfecting in the form of vapour.

The experiments were partly carried out in large glass bell-shaped vessels, and partly in a chamber of 1 cb. m. capacity. The action of the commercial formalin solution on the vegetative kinds of bacteria was scarcely stronger than that of carbolic acid in the same condition; the action was the same whether the bacteria were free or contained in albumin. On spores of cattle distemper, formalin acted more powerfully than carbolic acid, but the action of sublimate was 14 times stronger. On the other hand, the vapour of formaldehyde showed a greater disinfecting power than its solution, and the moist object was found to be made sterile more easily than the previously dried one. The spores of bacteria taken from a thick sheep skin, such as is met with in practice (covered with dirt and grease), were destroyed in the course of 4 hours by the formaldehyde vapour from 1 c.c. of formalin per litre.

The experiments in the chamber showed that the vegetative forms of bacteria, notwithstanding the closest wrapping up, were destroyed in 6—10 hours on evaporation of 0.5 c.c. of formalin per litre of chamber space. Cholera baceilli were thus destroyed in 6 hours, the spores of cattle distemper and the bacteria from sheep skin, those found between the lining and folds of a dress, were destroyed after 16 hours, when, for every litre, 1 c.c. of formalin was evaporated. The vapour of formalin did not at all damage leather, furs, and fabrics, did not attack metals, and did not alter the colour of dyed stuffs.

The author found that disinfecting at a higher temperature reduced the period of action and the quantity of disinfectant necessary. He doubts, however, whether the effective disinfection of a whole living room can be brought about by means of formaldehyde vapour.—A. S.

XIX.—PAPER, PASTEBOARD, Etc.

Paper, Testing of. W. Herzberg. Mitt. aus der Königl. tech. Versuchsanst. zu Berlin, 14, 1896, [2], 119—122.

THE testing of four samples of tissue copying paper gave the following results:—

Sample.	Mean Breaking Length.		Mean Stretching Power.	Composition of Fibre.	Mean Absorbing Power (Height).
No.					Mm.
1	Dry, 5,050 m.	Wet, 165 m.	Dry, 2.2 per cent.	Linen and cotton	12.5
2	Dry, 4,200 m.	Wet, 277 m.	Dry, 1.8 per cent.	Linen, cotton, wood and straw cellulose	12.5
3	Not tested	Not tested	Not tested	" " " "	9.5
4	"	"	"	" " " " " "	16.5

Of two other samples, one (No. 5) gave a good clean copy, while in the other (No. 6) the ink spread and the letters were with difficulty deciphered. In quality and quantity of the fibrous and mineral constituents, these two samples were practically the same. The absorbing capacity differed in the two samples, No. 5 having a mean absorbing height of 14 cm., and No. 6, 19.5 cm., but whether this accounted for the difference in the papers could not be ascertained.

Strength of Paper.—The strength of paper is generally greater lengthwise than crosswise, the proportion being from 60:100 to 75:100; the extensibility being the reverse, *viz.*, greater crosswise than lengthwise, the proportion varying considerably, sometimes from 100:100 to 297:100. With copying paper, the author found the extension is greater lengthwise than across, as shown by the following table of results:—

Sample.	Direction of Machine.		Crosswise to Machine.	
	Breaking Weight.	Extension.	Breaking Weight.	Extension.
No.	Kilos.	Per Cent.	Kilos.	Per Cent.
1	1.60	2.4	0.73	2.0
2	1.68	2.6	0.80	2.0
3	1.56	2.6	0.78	1.9
4	1.46	2.3	0.77	2.0
5	1.54	2.0	0.84	2.0
Average.....	1.58	2.4	0.78	2.0
Breaking length.....	6,750 m.		3,350 m.	

In a second series of tests the same observations were made, but in a less distinct manner. A normal water-marked writing paper (3 b) gave the following results:—

Sample.	Lengthwise.		Crosswise.	
	Breaking Weight.	Extension.	Breaking Weight.	Extension.
No.	Kilos.	Per Cent.	Kilos.	Per Cent.
1	6.67 kilos, and 1.6 per cent.		4.65 kilos, and 1.7 per cent.	
2	6.69 " 1.8 "		4.64 " 1.8 "	
3	6.74 " 1.7 "		4.62 " 1.4 "	
4	6.83 " 1.8 "		4.83 " 1.8 "	
5	7.22 " 1.8 "		4.19 " 1.6 "	
Average	6.82 kilos, and 1.7 per cent.		4.59 kilos, and 1.6 per cent.	
Breaking length.....	4,850 m.		3,300 m.	

—S. P. E.

Waste Sulphite Liquor. C. D. Ekman. Papier Zeit, 69, 1896, 2218—2219.

THE experiments of Ahrens as to the precipitation of the organic matter contained in the sulphite liquor, are valuable in showing that there are no prospects of success in this direction, and these experiments are fully in accord with those of the author.

One of the earliest to direct attention to the utilisation of waste sulphite liquor was Mitscherlich, who tried to use the liquor for the purpose of tanning hides, though without success—no doubt due to the absence of any tanning material in the liquor.

In Carl Hoffman's "Handbuch der Papier Fabrikation," there are mentioned certain patents obtained by Mitscherlich for using sulphite liquor for the preparation of paper size, but no practical results followed the use of this process.

A very interesting patent was taken out by Cross and Bevan in 1883, in which they proposed to manufacture both a sizing material and mordant, by adding glue or gelatin to sulphite liquor, and to dissolve the precipitate in sulphites or alkalis, by which means a sizing material, soluble in hot water, is obtained, which is precipitated by alum, sulphate of alumina, or an acid. It was called Gela-lignosine, and is identical with what Mitscherlich many years later called "*Gerb-leim*" (this Journal, 1883, 541). This Gela-lignosine has been now so far perfected in England that it may be used for the best class of white papers without affecting the colour more than the usual animal size does. Very satisfactory results have been obtained by its use, samples sized with it in the beaters showing an increase in strength in the weakest direction, of 50 per cent. over the same paper sized with rosin. It also gives the paper an excellent "surface," and writing may be erased and rewritten without the ink spreading. The only drawback to the manufacture of it on a large scale is the high cost. A recent process is the manufacture of "dextrine," which is a kind of dextrin, from the sulphite liquor, which process has been patented by the author. By this process the liquor is first evaporated to a very thick liquid, and then, by adding a suitable salt, the "dextrine" floats on the top as a paste. This "dextrine" is then dried, powdered, and packed in the usual manner. The "dextrine" is used in the textile manufacture, and it is said that cloth treated with it will not suffer from damp or mildew, as it does when the usual dextrin is used.

To get rid of the sulphite liquor some mills have tried to drain it into the earth, either by using wells or spreading it over a large area, but the results have been most unsatisfactory. After a time the decomposed or partly oxidised sulphite liquor, in the form of a dark, ill-smelling liquor, finds its way into the watercourses and wells in the neighbourhood, rendering the water unfit for use.

The quicker the sulphite liquor is got rid of the better, and it should be diluted as much as possible before being run into any river. In large rivers, where the percentage of sulphite liquor to water is very small, an oxidation is probably effected and ill-effects avoided.

The best means yet known, where a large river or the sea is not close at hand, is to evaporate the liquor, and condense the steam, so as to prevent pollution of the air.

—S. P. E.

Sulphur, Separation of, during the Boiling of Wood with Bisulphite Liquor. A. Haupf. Wochenblatt. für Papierfabr. 1896, 1761—1763, and 1911—1916.

THE Papier Zeit, No. 16, 1896, contains an article signed H. D., and Dr. A. Frank (Papier Zeit, 1896, [19]) contributes some notes, upon the Salomon-Bruggler wood-pulp digester. The former writer says: "The finish of the boiling was ascertained by the smell and colour of the liquor." The liquors, containing only a small quantity of free acid, he also observed, were turbid, and after carefully bottling samples and allowing them to stand, a distinct deposit was formed. This sediment was washed and filtered, and upon examination was found to be free sulphur. The lower the percentage of SO₂ present, the greater was the amount of sulphur precipitated. "This separation of sulphur, it is stated, was only found in liquors from the Salomon-Bruggler digesters, and not in the cylindrical digesters of the Ritter-Kellner and other systems." The incrustation deposited in these digesters, according to H. D., contained CaOSO₃, CaSO₃, a trace of iron, organic matter, CaS, and free sulphur. In No. 19 of the Papier Zeit., Dr. Frank points out that the statements of H. D. are of value, both as regards the theory as well as the practice of boiling wood. It is evident that the separation of sulphur from sulphite liquors was a fact hitherto unknown to H. D. and Dr. Frank. The following analysis of the deposited crust from sulphite digesters is also given by Dr. Frank:—

	Per Cent.
Calcium sulphite	62.23
Calcium sulphate	26.77
Water and organic matter	9.93

The presence of CaS in the incrustation may be explained as follows:—The first deposit upon the metal shell of the boiler and steam pipes will be calcium monosulphite, upon which new layers of the same salt will be deposited at each boiling. The first layer, being protected from the liquor by the subsequent layers, is liable to be overheated, which would cause it to be decomposed thus:—

The temperature was 153° C. (5 atmospheres pressure).

The presence of free sulphur is probably due to the decomposition of the CaS by SO₂ with the liberation of SH₂, thus:—

This SH₂ meeting nascent SO₂ is decomposed, liberating sulphur, thus:—

Another reaction may also take place when SH₂ and SO₂ are brought in contact with each other, with the formation of pentathionic acid and free sulphur, thus:—

When pentathionic acid is heated, it also decomposes and forms free sulphur.

With reference to the presence of precipitated sulphur in liquors from over-boiled wood, the remarks of H. D. simply confirm numerous previous tests. In speaking of a boiling, the author (Papier Zeit, 1891, [18]) then said: "The liquor was dark brown, turbid, and without any smell of SO₂, but of a disagreeable sweetish odour. Ammonia gave no

precipitate, and it was easily seen that the wood was over-boiled." A reliable test of the amount of SO_2 in the liquor could not be made with iodine, as organic matter was present, although 0.0316 per cent. of SO_2 was found. The presence of organic matter ought to have been taken into consideration in the tests made by H. D., who only observed the separation of sulphur in cases where the SO_2 present was less than 0.12 per cent.

It is further stated in the article in *Papier Zeit.* of 1891: "After standing for a few hours, a whitish deposit is formed, which was at first thought to be calcium monosulphite or the sulphate. No sulphurous or sulphuric acid or lime could be detected, but it was found to be pure sulphur." (See Nos. 38 and 39, *Papier Zeit.* 1892.) In *Papier Zeit.* No. 92, the author (Harpf) divided the boilings into regular or perfect cookings, and irregular or imperfect cookings. The liquors from regular cookings are never cloudy, but perfectly clear and brown, and do not give a deposit of sulphur. This deposit, however, can be obtained by treating the liquor with hydrochloric acid and allowing it to stand for some time. A flask filled with ordinary liquor was acidified with hydrochloric acid and allowed to stand on the steam boiler, and after a few days a distinct deposit of sulphur was found.

The sulphur is found in one or more of the following conditions:—

(1.) A small portion as SO_2 in the calcium sulphate, in the liquor of good cookings.

(2.) A further portion as SO_2 , partly free and partly combined, but in a form that may be titrated with iodine solution.

(3.) Another part is contained as SO_2 in the liquor, but in a combined form, which can only be freed by treating with strong acid.

(4.) The last portion of the sulphur exists combined with foreign organic matter, and can only be liberated by heating with hydrochloric acid.

The simplest way of obtaining this precipitate is to add water, acidify with HCl , and heat for a considerable time at a moderate temperature. At first the liquor will turn dark, and then clear, and then, after some time, sulphur is deposited. The above refers to Mitscherlich liquor, which is more concentrated than the liquor of most other processes.

With irregular or over-cooked boilings the liquor changes its odour, which becomes sweetish and disagreeable, the solution passing from a clear yellow to a dark brown, with a precipitate of sulphur. By over-boiling, the organic lime salts decompose, liberating free sulphur, which finally settles.

The author has seen a liquor that deposited sulphur taken from a South Austrian mill worked by Kellner's system.

Some years ago he heated some wood under pressure in glass tubes with bisulphite of lime, and distinctly recollects that the wood was over-boiled through the temperature being too high, and the liquor deposited lime and became dark brown and cloudy. The change in the smell of the liquor and the deposition of sulphur are two signs of over-cooking, and if the boiling be continued the liquor becomes darker and darker, with a deposit of calcium monosulphite. This is easily noticeable in the Mitscherlich boiling, whereas with direct steam boiling it is not so easy to detect the deposition of calcium monosulphite.

At a Mitscherlich sulphite mill where an imperfect boiling had been produced, the author saw amongst the pulp large quantities of monosulphite of lime mixed with free sulphur, which is a certain proof that the process of boiling does not involve the oxidation of sulphurous acid, but is, as pointed out in 1891 by him, substantially a reduction process.—S. P. E.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

Active Principles, Localisation of. Pharm. J. 1896, [1866], 177—178.

M. SACVAN gives the result of his observations on the distribution of a number of alkaloids and glucosides in the living plant.

Strychnine.—In *Strychnos nux vomica* and other species of the genus, strychnine occurs in the cortical parenchyma and liber of the root and stem, both in old and young plants; in the parenchyma of the leaves and liber of the veins; and in all the cells, both of the embryo and of the endosperm, in the ripe seed, always in their interior.

Brucine accompanies strychnine in all the organs where it occurs in the various species of *Strychnos*; it is also present in smaller quantities in the epiderm of the leaf and of the young stem.

Curarine is found in various species of *Strychnos*, in the interior of the cortical parenchymatous cells and in those of the liber, in the root and stem; also in the epiderm of the young stem and the cells of the parenchyma and liber of the root, stem, leaf-stalk, and leaf, and even in the pith of the stem.

Berberine occurs in *Berberis vulgaris*, in the interior of the cells of the cortical parenchyma, liber, cambium, and medullary rays, and in the interior and walls of the xylem vessels in the root, in the interior of the cells of the cortical parenchyma, liber, and cambium of the stem, and in all the cells of the embryo and endosperm.

Tarine of the yew is found in the parenchymatous and pericyclic cells of the root, but not in the sieve tubes; in the same elements and also in the pith of the stem; in the epiderm and the pericyclic and liber cells of the leaf; and in all the cells of the embryo and endosperm of the seed.

Helleborine and **helleboreine** occur in the same organs, though not usually in the same cells of various species of *Helleborus*. *H. viridis* is the richest in helleborine; *H. niger* in helleboreine.

Daphnine occurs in special abundance in the fruit of *Daphne alpina* and *D. genkium*.—A. S.

Benzoylquinine. A. Wuosch. Nordisk. pharm. Tidsskrift, 1896, 3, 213.

BENZOYLQUININE rotates a beam of polarised light to the right to the same extent as quinine itself does to the left, but addition of hydrochloric acid decreases its optical activity. All its salts are acid, and in dilute aqueous solution they are fluorescent. Benzoylquinine forms normal salts with 2 mols. of a monovalent acid, and also basic compounds with half that amount. The latter are stable, crystalline, and not readily soluble in water; the normal salts are more difficult to prepare and more easily decomposed, even by water. The author has prepared the following compounds. Basic hydrochloride—

basic hydrobromide, basic salicylate, basic tartrate, containing 9 mols. of water, &c. The normal hydrochloride, $\text{C}_{20}\text{H}_{23}(\text{C}_6\text{H}_5\text{CO})\text{N}_2\text{O}_2 \cdot 2\text{HCl} + \text{C}_2\text{H}_5\text{OH}$, is obtained as a white powder by the action of hydrochloric acid gas on a solution of benzoylquinine in absolute ether. The base combines readily with alcoholic iodides—compounds with 1 and 2 mols. of methyl iodide having been produced, the former as white or yellow needles, and the latter as a red crystalline mass.—F. H. L.

Aconitum Septentrionale (Koele). *Pharmacological Researches on.* H. V. Rosendahl. J. Pharm. Chim. 1896, 4, 262.

The three following alkaloids have been obtained from the above species of *aconitum*:—

Lupaconitine, $\text{C}_{34}\text{H}_{48}\text{N}_2\text{O}_8$, well-formed voluminous hexagonal crystals, melting at 205°, with a bitter taste. The alkaloid and its salts are dextro-rotatory. It dissolves in 126 parts of alcohol, 330 of ether, 1,472 of water, and the solutions have a violet-red fluorescence. With sulphovanadic acid it gives at first a yellowish-red coloration, and with bromine, tribromolupaconitine. When heated with alkalis, two other alkaloids, of melting points 98° and 106° C., and an acid not containing nitrogen, are produced.

Septentrionaline, $\text{C}_{31}\text{H}_{48}\text{N}_2\text{O}_8$, is a white or yellowish powder with a bitter taste, melting at 128.9° C., and, together with its salts, is dextro-rotatory. It dissolves in 1.7 parts of alcohol, 2.1 of ether, and 58 of water; the solutions do not fluoresce. The solution of the alkaloid in freshly prepared furfural sulphuric acid, is cherry-red in

colour. This alkaloid also forms a tribromo derivative, and warmed with caustic soda gives alkaloids, melting at 88° and 105° C., and an acid identical with that obtained from lapaconitine.

Cynoctonine, $C_{36}H_{55}N_3O_{13}$, is an amorphous unstable greyish powder with a bitter taste, easily soluble in alcohol, dissolving in 1,373 parts of ether and 23 of water. These solutions do not fluoresce. It is dextro-rotatory, and melts at 137° C. Concentrated sulphuric acid colours it a deep brown; evaporated to dryness with fuming nitric acid, it leaves a residue which, with alcoholic potash, gives a blood-red coloration, changing at once to brownish-red. With bromine, tribromoecynoctonine is produced.—A. C. W.

Alkaloid from Kopsia Flavida. Separation and examination of the. W. P. H. v. d. Driessen. *Marceuw. Nederl. Tijdschr. Pharm.* 8, 199—204.

An alkaloid was first isolated from the *Kopsia Flavida*, belonging to the family of the *Apocynaceæ*, by Greshoff (Ber. d. botan. Gartens zu Buitenzorg, 1890, 60). The author obtained it from the bark of the plant by extracting with alcohol, taking up the residue of the alcoholic solution with dilute hydrochloric acid, and shaking the liquid, supersaturated with ammonia, with chloroform. To purify the crude product, he dissolved it in dilute hydrochloric acid, treated again with ammonia, shook up with chloroform, then in like manner with ether and with petroleum spirit. The alcoholic solution of the white residue, on spontaneous evaporation, left the alkaloid in the form of small prisms. The chloride, sulphate, and acetate also crystallise. With the alkaloid group reagent, a precipitate was formed. With Mayer's reagent, iodine dissolved in potassium iodide solution, the double iodide of potassium and bismuth, and with phosphomolybdic acid, about 1 part in 20,000 may be detected. Strong sulphuric acid is coloured yellow by it, with warming, violet; concentrated hydrochloric acid and potassium bichromate, after 5 minutes, purple-violet; cerium oxide and sulphuric acid, violet. Red fuming nitric acid evaporated to dryness on the water-bath with a trace of the alkaloid gives a green colour, changing to brownish-red with caustic soda; nitro-sulphuric acid produces a reddish-violet colour. With bromine water is formed in a weak acid solution, an addition product. The physiological action of the alkaloid is weak.—A. S.

Bebirine (or Bebeerine). M. Scholtz. Ber. 1896, 29, 2054.

This alkaloid, investigated by MacLagan in 1843, was obtained by him in an impure form from the bark of *Nectandra Rodiei*, a tree indigenous in British Guiana. The pure alkaloid may be obtained in the form of small colourless crystals by dissolving the amorphous variety in methyl alcohol. The crystals melt at 214° , dissolve with difficulty in methyl and ethyl alcohols, from which solvents the crystalline form again separates; they are readily soluble in acetone and chloroform, the amorphous form separating from these solutions. The crystalline hydrochloride melts at $259-260^{\circ}$, and is formed on evaporation of the hydrochloric acid solution of crystalline bebirine. Bebirine, $C_{18}H_{21}NO_3$, is optically active; $\alpha_{D}^{20} = -298$. On oxidation with potassium ferrieyanide, it yields the base $C_{15}H_{19}NO_4$.—A. C. W.

Scopolamine. E. Schmidt. Ber. 1896, 29, 2009.

O. Hesse has stated that commercial scopolamine hydrobromide is a mixture of the hydrobromide of hyoscyne, $C_{17}H_{23}NO_3$, and an isomeric base, atropine. This the author denies, the samples with low optical rotation are mixtures of scopolamine hydrobromide $C_{17}H_{21}NO_4 \cdot HBr + 3H_2O$ with a hydrobromide of inactive scopolamine—

The inactive alkaloid is obtained from the active by the action of alkalis, and the samples of normal rotation $\alpha_{D}^{20} = -25^{\circ} 43'$, are obtained by making the extract alkaline with sodium bicarbonate or ammonia, those of weak rotation $\alpha_{D}^{20} = -6^{\circ} 62'$, by the use of strong potash or soda. The salts of the active and inactive bases are identical in crystalline form and in their therapeutic effect.—A. C. W.

β -Asparagine, Formation of. A. Piutti. Ber. 1896, 29, 2069.

By the action of concentrated alcoholic ammonia on maleic anhydride at 105° — 110° there is produced a mixture of the two asparagines, identical with the natural product.

—A. C. W.

Stachydrine, Occurrence of, in the Leaves of Citrus Vulgaris. E. Jahns. Ber. 1896, 29, 2065.

By extracting the orange leaves with boiling water, precipitating with lead acetate, adding sulphuric acid, and throwing down the bases with potassium bismuth iodide, and treatment of the precipitate with silver or barium carbonate, a solution of a base was obtained which, after recrystallisation, possessed the formula $C_{12}H_{15}NO_2 + H_2O$, and was identical with stachydrine. This is a monobasic acid, and on evaporation with strong potash and heating until the potash melts, the mass evolves dimethylamine. Thus the formula $C_{11}H_{14} \cdot N(CH_3)_2(CO_2H)$ is indicated.—A. C. W.

Digitoxin. Kiliani. Archiv. der Pharmacie, 234, 181.

The author obtained, on a former occasion, by treating the alcoholic extract of digitalis leaves with ether, a crystalline glucoside, which presented the same characteristics as the digitoxin described by Schmiedeberg, and he provisionally called it β -digitoxin (Pharm. J. 55, 120). Further examination of digitoxin, prepared according to Schmiedeberg's method, has shown that it is a glucoside, and really the same substance as the author obtained in his experiments. By treating digitoxin with an alcoholic solution of hydrochloric acid, without heating above 25° C., it dissolves after four or six hours, and on adding some water, crystals of digitoxigenin are deposited. After leaving the mixture for several hours, and filtering, the filtrate is shaken with chloroform, which is separated and distilled, and the syrupy residue washed into a basin with proof spirit, and warmed to drive off chloroform, when more digitoxigenin will be deposited. The aqueous liquid separated from the chloroform is shaken with sufficient silver oxide to remove hydrochloric acid, filtered, and evaporated in a vacuum to syrupy consistence. After some time, crystalline crusts are formed, which are dried upon clay slabs, and when dissolved in the least possible quantity of methyl alcohol, form, on addition of ether, fine prismatic crystals of digitoxose, melting at 101° C. Taking the composition of digitoxose to be $C_{20}H_{32}O_{10}$, and that of digitoxigenin to be $C_{20}H_{30}O_8$, that of digitoxin would be $C_{20}H_{30}O_{10}$, which agrees with the analytical data obtained. The author considers that the substance described by Arnaud (this Journal, 1890, 323 and 324) as "digitaline crystallise," melting at 213° — 245° C., was probably digitoxin. It was found that the seeds of digitalis contained a comparatively large amount of digitogenin, but no digitoxin.—A. S.

New Toxic Glucoside. Plugge. Arch. de Pharmacodyn, 2, 537.

The bark of *Lumnisa amara*, a tree also known as *Rabulaisia philippinensis*, and growing in the island of Luzon, is used there by the *Negritos* as an arrow poison. Plugge finds that this bark contains a very toxic glucoside, acting on the heart like digitalin, 0.01 grm. of it killing a frog. The glucoside is soluble in water and alcohol, less in chloroform, and is difficult to extract by the latter solvent. The chloroformic solution can, however, be obtained colourless, and on evaporation in a desiccator, gives crystals which are deliquescent in the air.—A. S.

Coronilla and Coronillin. F. Schlagdenhauffen and E. Reeb. Zents. Oesterr. Apoth.—V. 34, 487—490.

The authors have examined the constituents of the coronillas, viz., the seeds of the *Coronilla scorpioides*. From the pulverised seeds, by means of petroleum ether, an orange-yellow fatty oil was obtained (4.3 per cent.), sp. gr. 0.912, which turns brown with sulphuric acid and violet on addition of ferric chloride. It contained cholesterin, some lecithin, and yielded, by saponification, arachidic, stearic, and palmitic acids.

Coronillin.—1 kilo. of the oil from the pulverised seeds was digested for six hours at 100° C., with six times its own volume of water, and the mass, after cooling, was mixed with its own volume of 95 per cent. alcohol. After standing for three days, the mixture was filtered and evaporated to one-sixth of its weight. After 24 hours, crystals having the formula $C_{17}H_{15}O_5$ separated out, which, on account of a cumarin-like odour which was apparent when they were heated, were called *pseudo cumarin*. The liquor filtered from the crystals was evaporated to a thick extract, which was dissolved in 95 per cent. alcohol (3 litres of alcohol to 50 grms. of extract), the solution filtered, the alcohol distilled off, and the residue dissolved in water and shaken up with ether. The ether extract was decomposed on the water-bath with sodium and magnesium sulphates, whereby a thick mass separated out, which was dissolved in alcohol. The filtered alcoholic solution was then decomposed with lead acetate, the filtrate freed from lead by H_2S , filtered, evaporated to dryness, dissolved again in water, filtered through unglazed porcelain, and again evaporated to dryness. The residue, washed with chloroform and ether and dissolved in very little alcohol, was finally mixed with ether, and the filtered yellowish solution evaporated. Coronillin was thus obtained as an amber-yellow powder. Formula $C_{17}H_{15}O_5$, soluble in water, alcohol, and acetone, with difficulty soluble in ether and chloroform. It is a glucoside, and splits up on dilution thus:—

Coronillin gives, with H_2SO_4 , $H_2SO_4 + Br$, $FeCl_3$ and KI , almost the same reactions as specimens of the commercial digitalin (yet not the blue reaction with Lafont's reagent) and is distinguished by a characteristic cherry-red to reddish-brown colour, which is formed on the addition of nitric acid and a trace of chlorine. In its physiological action, coronillin closely resembles digitalin (glucoside).—A. S.

Malarin [Acetophenone-phenetidine Citrate]. Pharm. Zeit. 41, 598.

This is the citrate of a condensation product of acetophenone *p*-phenetidine, is insoluble in cold water and has a slightly acid taste. The condensation product (acetophenone-phenetidine) is prepared by heating equivalent proportions of acetophenone and *p*-phenetidine, either alone or with addition of dehydrating agents. It crystallises in yellow needles, melting at 88° C., and is readily soluble in hot alcohol, ether, or glacial acetic acid.—A. S.

Amyloform. Claassen. Pharm. Zeit. 41, 615.

The author has obtained by the action of formic aldehyde upon starch, an inodorous white powder, insoluble in any menstruum, and having a very marked antiseptic character. Under the microscope it does not show any structure of starch. When applied to surgical dressings, they can be sterilised without fear of alteration, as amyloform when heated to 110° C. loses 2.87 per cent. of water without being decomposed. It is stated to be preferable to iodoform as a dressing for wounds.—A. S.

Essential Oils and Essences from Government Flower Farm, Dunolly, Victoria: Report on Preliminary Examination of. J. C. Muncey. Imp. Instit. Jour., Scient. and Tech. Research Dept., Aug. 1896, 302.

Oil of Anise.—This oil has a density of 0.914 at 15°, an optical rotation of + 16 in a 109-mm. tube, and does not solidify at 1° C., it is thus very different from the slightly levo-rotatory oils of anise fruit and star anise, which have a density of 0.980–0.990 and solidify at 14° C. The odour is more suggestive of fennel than anise, and so are the physical constants. It did not appear from a comparison with the liquid portion of anise oil that the difference was due to the solid parts being separated by the use of ice water in the condenser. No commercial value can be placed on the oil in the form in which it was examined.

Oil of Absinthe.—The sp. gr., 0.939, lies between that of the English and American oils; the optical rotation could not be discovered owing to the dark green colour of the oil,

but on fractionation it gave the following result as compared with a pure American oil:—

	Below 200° C.	200° —205° C.	205° —210° C.	Above 210° C.
	Per Cent.	Per Cent.	Per Cent.	Per Cent.
Dunolly	4	20	28	48
American	15	12	14	59

Oil of Boronia Polygalifolia.—This oil might be largely employed in perfumery. It is new to commerce, has a sweet smell resembling tarragon, with a slight after-smell of rue. A complete chemical examination is desirable. The specific gravity is 0.839 and the optical rotation + 10. On fractionation the following results were obtained:—

	Per Cent.
150°—170° C.	31
170°—180° C.	38
180°—190° C.	15
Above 190° C.	16

The ketone, boiling at 225°, characteristic of rue oil, does not therefore exist in any quantity in this oil; the highest fraction gave no crystalline compound with sodium bisulphite.

Oil of Eucalyptus citriodora has a powerful citronella odour, a specific gravity of 0.8809 and an optical rotation of -1. On fractionation it gave—

	Per Cent.
190°—200° C.	76
210°—219° C.	12
Residue	12

The aldehyde citronellon was present to the extent of 90 per cent., no eucalyptol was found by the phosphoric acid test. The oil has no medicinal value, and probably could not be produced to compete with citronella oil for perfumery purposes, the odour of the latter oil, however, is modified by the presence of a considerable percentage of geraniol.

Essences of Jonquille, Milkflowers, and Tuberoze.—These samples were useless for perfumery purposes, owing to insufficient concentration and the use of non-odorless spirit. No fat could be separated by freezing, hence they had probably not been prepared by the "enfleurage" process. Probably the essences would be valuable if carefully prepared by this process.

The aroma of the jonquille is good, and of the tuberoze fair; that of the milkflowers is spoiled by the presence of sage or absinthe.

Oil of Rose Geranium and African Geranium.—From the following figures it will be seen that these oils show no great deviation from the French and African geranium oils:

	Specific Gravity.	Optical Rotation.	Total Geraniol.
Dunolly rose geranium	0.906	- 11.25	51.8
" African geranium	0.902	- 7.5	62.4
French rose geranium	0.894	- 10.75	57.1
African geranium	0.898	- 7.5	69.6

Oil of Lavender.—The specific gravity was 0.916, the optical rotation + 11; these figures point to the possibility of the oil having been distilled from a mixture of *lavandula vera* with *lavandula spica* or other lavenders. The proportion of esters was 5.25 per cent.; most English samples show 7–10 per cent. The alcohol $C_{10}H_{18}O$ was present to the extent of 29.75 per cent.; the oil of *lavandula vera* usually contains about 45 per cent.

Oil of Lemon Thyme.—After removal of added alcohol (20 per cent.), the specific gravity was 0.898, and the rotation - 3. A fractionation gave this result—

	Per Cent.
210°—220° C.	28
220°—230° C.	54
Above 230° C.	18

The first fraction consisted almost entirely of citral; the second showed a large proportion of phenols, chiefly, if not entirely thymol.

Oil of Myrtle.—The specific gravity was 0.926, the optical rotation -4 ; after removal of 28 per cent. of a non-volatile residue, a mixture of a caoutchouc-like substance, with a wax of melting-point 45°C ., the purified oil gave the following results, which are compared with two French samples:—

Sample.	Specific Gravity.	Rotation.	Fractionation			
			Below 170°	170° — 185°	185° — 200°	Above 200°
			Per Cent.	Per Cent.	Per Cent.	Per Cent.
Dunolly.....	0.916	-5	18	9	20	43
France I.	0.885	$+25$	78	16	1	2
France II.	0.893	$+24$	56	24	6	14

Oil of Rose.—The sample was free from alcohol, had a specific gravity of 0.8886, and only became slightly opaque at 5°C .; whilst Turkish otto of rose solidifies at 17° — 20° , and has a specific gravity of 0.865—0.870. Probably the stearoptene had been partially removed in the condensation of the oil. In odour the sample compared favourably with Turkish otto.

Oil of Peppermint.—The specimen was of a pale greenish-yellow colour; the numbers in the following table, obtained after removal of added alcohol, show that it compares fairly well with other samples:—

Sample.	Specific Gravity.	Rotation.	Menthyl as Esters.	Free Menthol.	Total Menthol.
			Per Cent.	Per Cent.	Per Cent.
English (black)	0.9072	-18.5	5.6	57.5	63.1
" (white)	0.9058	-33.0	13.6	51.9	65.5
Dunolly	0.912	-27.0	8.3	45.6	53.9
American	0.9215	-29.0	8.4	38.0	46.4
Saxon.....	0.9057	-26.25	6.1	55.3	61.4

Oil of Pennyroyal had a marked peppermint odour in addition to that of pennyroyal, the further examination showed the sample to be a mixture of the two oils. Its specific gravity was 0.918, and rotation $+7$; the English and American pennyroyal oils have a specific gravity of not below 0.930, and the rotation is between $+18$ and $+20$. The specific gravities of most peppermint oils do not exceed 0.915, and their rotation is -20 to -30 . The following are results of comparative fractionations:—

Sample.	Below 210°	210° — 220°	220° — 223°	Above 223°
	Per Cent.	Per Cent.	Per Cent.	Per Cent.
Dunolly	43	34	13	10
American	4	79	12	5
English (old) ...	15	37	7	41

The percentage of alcohol (probably menthol) was, as ester 8.7, as free alcohol 27.5, calculated as menthol and menthylacetate. This is 10—15 per cent. more than is given by English and American oils.

Oil of Rosemary.—This oil is of exceptionally high borneol value, and compares with the finest English oil, as the following table shows:—

	Specific Gravity.	Rotation.	Fractionation.			
			Below 176°	176° — 200°	Above 200°	Borneol.
			Per Cent.	Per Cent.	Per Cent.	Per Cent.
Dunolly	0.906	$+0.25$	13	64	23	15.1
England (Lines)	0.9097	$+7.5$	14	73	13	13.26
France (Grasse)	0.9079	$+3.5$	22	59	19	11.07

Oil of Sage.—The oil so described had a strong thyme odour, quite different from the usual oil of sage from *salvia officinalis*; it contained 17 per cent. of phenols, with a boiling point of 232° — 233° (carvacrol), but was practically free from alcohols, whilst true oil of sage has 22—23 per cent. of alcohols, and only 2—3 per cent. of phenols. The sample has thus probably been distilled from *Satureja hortensis* (summer savory).

Oil of Tansy.—The specific gravity, 0.922, and rotation, $+37$, and the results of a fractionation (200° — 210°C ., 26 per cent.) show its identity with the American oil.

Oil of Thyme of the Alps.—The following comparison with samples of red and white oils shows the value of this oil and its freedom from oils of wild thyme and spike (*Larandula spica*):—

Distilled in	Specific Gravity.	Rotation.	Percentage of Phenols.	Remarks.
Dunolly	0.922	37	23	Pure.
France	0.901	15	11	Mixed with oil of Lavandula spica.
France	0.926	44	49.4	Pure.
Germany, white ..	0.925	38	34	Pure.

Oil of Vervain.—The sample had the characteristic odour of the verbenia or lemon-grass oil, though much more agreeable, it was probably, however, distilled from common vervain.

Lippia Citrodora.—The specific gravity was 0.891, the rotation -16 , fractionation under atmospheric pressure was unsatisfactory, because of considerable decomposition. The aldehydes (citral) amounted to 74 per cent. This oil would be of considerable value for soap and perfumery compounding, if it could compete in price with Ceylon lemon-grass oil.

The specific gravities mentioned in this paper were taken at 15°C ., and the optical rotations in a 100 mm. tube.

—A. C. W.

Bergamot Oil, Proof of the Purity of. A. Borntraeger. Zeits. anal. Chem. 1896, 35, 523.

In a former paper (this Journal, 1896, 223) the author adopted 38 per cent. of linallyacetate as the standard of purity of bergamot oil, whilst Schimmel and Co. had stated that the percentage varies between 34 and 43. In their April report, this firm states that of the last crop the oil of unripe and half ripe fruits contains 43—34 per cent., and of ripe fruits about 37 per cent. Only in the case of a few Parthian oils at the close of the season does the content rise to 40—44 per cent. Thus the saponification process must always be supplemented by determinations of density and optical rotation to detect a simultaneous adulteration with oil of turpentine and fats.—A. C. W.

Essential Oils. Dayk. J. Pharm. Chim. 1896, 4, 38 and 206.

Cinnamon Oils.—In Belgium the official oil is obtained from the bark of the Ceylon cinnamon; in other countries the oil of *cinnamomum cassia* is made use of. The principal constituent of both oils is cinnamic aldehyde. Ceylon cinnamon oil is a yellowish liquid of density 1.024, without action on polarised light (according to Umney it is slightly dextro-rotatory), and should not contain less than 60 per cent. of the aldehyde. A solution of a few drops in 10 c.c. of alcohol should give a pale green coloration with ferric chloride; deep blue or green indicates the presence of essential oils of the leaves or roots, which both contain a large percentage of eugenol; a brown coloration is produced by oil of cassia. The Ceylon oil contains 6—8 per cent. of eugenol, a terpene (probably phellandrene), small quantities of safrol, a stearoptene, &c. The oil of cinnamon leaves is characterised by the presence of much eugenol and little cinnamic aldehyde; the oil of the roots also contains much eugenol and a camphor, but only traces of aldehyde. Chinese cinnamon oil or oil of cassia contains

70--80 per cent. of aldehyde, also cinnamyl-acetate, eugenol, a terpene, and a camphor, which last is an aldehyde and is transformed by oxidising agents into β -methylcoumaric ether. It is a deep yellow liquid of density 1.055—1.065; the alcoholic solution gives a brown coloration with ferric chloride. Oil of cassia should give no precipitate on shaking with water, filtering and adding basic lead acetate. On distillation the residue should be syrupy, and not amount to more than from 8—10 per cent., and on adding to a solution of 1 c.c. of the oil in 3 c.c. of 70 per cent. alcohol a mixture of 2 c.c. of saturated lead acetate solution and 4 c.c. of 70 per cent. alcohol, no precipitate should be obtained. The best test of the purity of a cinnamon oil is an estimation of its aldehyde content. Schimmel's process for this is as follows:—10 c.c. of the oil are placed in a 100-c.c. flask with a long neck graduated in $\frac{1}{10}$ c.c.; the flask is then three-quarters filled with a 30 per cent. sodium bisulphite solution. After shaking and warming, more bisulphite solution is added, so that the bisulphite compound having dissolved, the oily layer enters the neck of the flask and its volume is then read off. Subtracting this from the 10 c.c. of oil used, the volume of aldehyde is obtained, and hence the percentage, the aldehyde and mixture of other constituents having approximately the same density. An oil containing less than 70 per cent. of aldehyde should be regarded with suspicion; oil marked Cheong-Loong and Yang-Loong have given the highest values.

Caraway Oil.—A good sample should have a density of at least 0.910 at 15° C., not more than 15 per cent. should distil over below 185°, and 55 per cent. should come over above 200° C. The rotatory power varies from 79° to 80°. On keeping, a phenol is formed; to this is due the blue coloration given by ferric chloride.

Anise Oil.—The density is between 0.980 and 0.990 at 15°, and the rotation is about + 4.5° in a 200 mm. tube. At 9° it almost entirely solidifies to a crystalline mass of anethol. The proportion of this constituent is determined by strongly cooling and pressing the crystalline mass between absorbent paper: a good sample should not contain less than 85 per cent. of anethol. On keeping it becomes acid through oxidation. The properties of this oil are very similar to those of star-anise, from which it is distinguished by giving an intense blue coloration on addition of a solution of hydrochloric acid gas in absolute alcohol, oil of star-anise producing a brownish colour.

Fennel Oil solidifies at 5°—10° C., its density should not be less than 0.950. Adulteration with turpentine may be detected by examination of the lowest boiling fraction and by determination of the optical rotation; this is + 6.75 for the pure oil, the adulterated product being levo-rotatory. To estimate the substances for which this oil is valuable, the liquid estragol must be converted into the isomeric anethol by boiling with alcoholic potash, after which the anethol may be determined as above.—A. PATENTS.

Alimentary or Pharmaceutical Liquids or other Substances, and in Apparatus therefor; Impts. in Concentrating. S. D. Rowland, London. Eng. Pat. 17,061, Sept. 12, 1895.

See under XVIII. A., page 733.

Pharmaceutical Substances, The Manufacture of. [Active Substance of Thyroid Glands.] Farbenfabriken vormals F. Bayer and Co., Elberfeld, Germany. Eng. Pat. 20,827, Nov. 4, 1895.

Processes are claimed for isolating and preparing the active principle of thyroid glands. The thyroid glands of sheep (or other animal) are heated, either with (a) 3 per cent. sodium hydrate solution, or (b) With water only, under pressure at 180° C. The solution after filtration (a) is acidified, when the thyroidea is precipitated; (b) Deposits the active constituent in flocks on cooling. In either case traces of thyroidea still remaining in solution may be separated by addition of salt. The impure product is dissolved in hot alcohol, the solution filtered and allowed to cool, when fatty acids, if present, will crystallise out, and may be filtered off. Finally, the solution is evaporated to dryness in order to obtain the thyroidea, or, if a very pure product be required, precipitation with ether may be resorted to.—H. T. P.

Vanillin, Impts. in the Manufacture or Preparation of. C. F. Boehringer and Soehne, Waldhof, Germany. Eng. Pat. 22,351, Nov. 22, 1895.

The production of vanillin from its ethers (benzyl-vanillin, &c.), by hydrolysis of the latter with halogen acids, as claimed in Eng. Pat. 361, 1892 (this Journal, 1893, 61), is improved upon by effecting the operation in presence of an alcohol. By this means the proportion of acid required for hydrolysis may be much reduced, on account of the fact that the halogen alkyl ordinarily formed in the course of the reaction is at once decomposed by the added alcohol, free acid being regenerated. For example, starting with benzyl-vanillin, ethyl alcohol (and HCl), the end-products are vanillio, benzyl-ethyl ether (and HCl). In practice the proportion of acid may be reduced to one-fifth of that demanded by theory (alcohol being absent).—H. T. P.

Sugar, Ferric Oxide, and Chloride of Sodium [Medicinal Preparation]; Impts. in or relating to the Manufacture of a New Product from. C. Stahlschmidt, Bartscheid, Germany. Eng. Pat. 7793, April 13, 1896.

A MEDICINAL preparation. 600 grms. of sugar are dissolved in 1 litre of ferric chloride solution (sp. gr. 1.049), and diluted with 0.5 litre of water. The solution is then heated to from 80°—100° C., and 640 c.c. of caustic soda solution (sp. gr. 1.0985) added, and the whole evaporated to dryness on a water-bath. A black, shining, amorphous mass is thus obtained. The preparation is soluble in three times its weight of water. The solution is not precipitated either by the common mineral and organic acids, or by salts (alum, sodium sulphate).—H. T. P.

Ozone, Impts. in Apparatus for the Production of. [Hollow Electrodes.] E. Andreoli, London. Eng. Pat. 10,372, May 14, 1896.

See under XI. A., page 726.

Ortho-Sulphamine Benzoic Acid ["Saccharine"], Preparation of. G. Cerekel, Paris, France. Eng. Pat. 15,493, July 13, 1896.

AN intimate mixture of ortho-cresol and ammonium bisulphite in equivalent proportions is heated for about 12 hours, preferably in a closed vessel, to a temperature not exceeding 150° C. The mass is then dissolved in hot water, and the unaltered cresol removed by steam distillation. The toluene sulphamine remaining in the solution is purified by crystallisation from water, and finally oxidised by potassium permanganate in the usual way.—H. T. P.

Albumin-Tannin Compound [Astringent], *Impts. in the Manufacture or Production of an.* W. L. Wise, London. From Knoll and Co., Ludwigshafen, Germany. Eng. Pat. 13,281, June 16, 1896.

THIS improvement on the patentee's previous specification (this Journal, 1896, 470) consists in substituting for the heating of the washed precipitate, the treatment of it with alcohol, or an acid, or formic aldehyde, any one of which will render the albumin-tannin compound with difficulty digestible in the gastric juices of the stomach.—A. G. B.

Pyrocatechin, Impts. in Mono-Alkyl Ethers of, and in the Production of such Ethers [Antiseptic and Odorant]. Chemische Fabrik von Heyden, Radebeul, Germany. Eng. Pat. 16,047, July 20, 1896.

THIS invention has reference to pyrocatechol-ethyl ether, which is described as a hitherto unknown substance. It is prepared by heating under pressure a solution containing pyrocatechol, sodium hydrate, and sodium ethyl sulphate (or ethyl chloride, &c.) in equivalent proportions. The pyrocatechol mono- and diethyl ethers thus formed are removed by steam distillation, and finally separated by treatment with caustic soda solution, in which only the monoethyl ether is soluble. Pyrocatechol-ethyl ether ($C_6H_4 \cdot OC_2H_5(OH)$) crystallises in large, well-developed, clear, colourless prisms. It fuses readily, and solidifies at 26° – 27° C. It boils at 215° C., and is soluble in alcohol and ether, with difficulty soluble in water. Its odour resembles that of thymol. Heinisch (Monatshefte für Chem. 15, 152) has described a substance which he supposed to be pyrocatechol monoethyl ether. This supposition is stated to be erroneous.—H. T. P.

New Perfume [Ethyl Homovanillin], and *Process for the Manufacture of the same.* Chemische Fabrik von Heyden, Radebeul, Germany. Eng. Pat. 16,162, July 21, 1896.

THE new perfume—ethylhomovanillin—is obtained by the action of chloroform on an alkaline solution of homopyrocatechol-ethyl ether. It crystallises from alcohol in colourless needles, melting at 91° C., and possesses an extremely persistent odour, resembling, but distinguishable from, that of vanillin. Ethylhomovanillin probably has the following constitution—

(see this Journal, 1896, 614).—H. T. P.

XXI.—PHOTOGRAPHY.

PATENT.

Photographs in Relief in Gold, Silver, and other Materials; Improved Means of Obtaining. A. Hill and A. A. Barratt, Surrey. Eng. Pat. 15,935, Aug. 24, 1895.

THIS is a process for making use of the relief existing on a bichromated gelatin film for the production of a plaster matrix, whence a metallic cast may be obtained by electrolysis or otherwise. The special aim of the present specification is to increase the ordinary low relief of the gelatin print; this being effected by cementing the exposed film to a plate of glass by means of isinglass dissolved in weak acetic acid containing also a little celluloid in amyl acetate, and developing first with water, and afterwards with 1 part of citric acid in 6 of water.

In the case of portraits with a light background, &c., false modelling is likely to occur, as the original negative indicates differences of colour as well as of form. To obviate this, either a silver print is prepared, the necessary corrections made with the brush, and a fresh negative taken from it; or the first negative may be kept very thin, intensified with uranium, and "reduced" where necessary with strong ammonia.—F. H. L.

XXII.—EXPLOSIVES, MATCHES, Etc.

PATENT.

Lucifer Matches [Coating with Inflammable Waterproof Mixture], *Impts. in.* P. Fowler and A. W. F. Bower, London. Eng. Pat. 15,574, Aug. 19, 1895.

THE heads and part of the stems of matches prepared in the usual manner, are soaked in a waterproofing mixture such as beeswax and rosin, or paraffin-wax, or a solution of india-rubber, gutta-percha, or shellac, "which, whilst absolutely preventing them from being injuriously affected by wet or damp, does not interfere with their ready and effective ignition when required." In some cases the waterproofing material may be incorporated with the composition of which the heads are made; and it is also suggested that the tips should be dipped in a "liquid or solid lubricant, such as oil or grease," to reduce the liability of adhesion or abrasion.—F. H. L.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS, ETC.

Pyrometers and their Errors. Wiborgh. Oesterr. Zeits. Berg-u. Hüttenw. 44, 1895, 495.

PYROMETERS depending upon the unequal expansion of two metals (e.g., spirals of silver and platinum) can only be used up to 300° – 400° C., on account of changes in the texture of the metals. Mercury thermometers containing nitrogen can only be used up to 450° – 500° . Air thermometers can be used up to $1,300^\circ$ – $1,400^\circ$, but are more adapted for laboratory than for workshop use. Calorimetric methods, in which a body of known mass and specific heat is allowed to drop into water, are liable to errors. Substances which melt at known temperatures can be used for pyrometric determinations; for high temperatures, only silver, gold, and platinum should be employed, as the other metals (and alloys still more) do not fuse at constant temperatures. A mixture can be made of quartz, felspar, kaolin, and marble in definite proportions, having melting points between $1,000^\circ$ and $1,800^\circ$; this can only be used for furnaces which are slowly heated up to a definite temperature. The author does not consider that the pyrometers of Siemens (depending on the change of resistance of a platinum wire) and Le Chatelier (consisting of a thermo-couple of platinum and platinum-rhodium) have proved satisfactory as practical instruments. Optical pyrometers, which measure the intensity of the light emitted by the glowing body, can be used for the highest temperatures. The best pyrometer is that of Mesuré-Nonel, which contains two Nicol prisms and a quartz plate. The composition of the light given out by a glowing body varies with the temperature; and for a given temperature the analyser must be rotated through a given angle to obtain the same transition tint. Finally, the author suggests the use of an apparatus which he calls a "thermophone." This contains an explosive mixture in a fire-resisting case; the time which elapses before the explosion occurs is used as a measure of the temperature.—D. E. J.

Thermophone, The: A New Pyrometer. Wiborgh. Berg-u. Hüttenw. Zeit. 55, 257–259.

THE apparatus consists of a fire-resisting cylinder (clay, graphite, &c.) in which is placed a closed metal capsule containing a small quantity of an explosive, which detonates at a constant temperature. This is placed in the space, the temperature of which is to be determined, and the temperature calculated (by reference to empirical formulæ or previously drawn curves) from the time which elapses before explosion takes place. Temperatures between 300° and $2,000^\circ$ can be estimated to within $\pm 20^\circ$.—J. T. D.

Auto-Pneumatic Stirrer. H. Brearley. Chem. News, 1896, 74, 63.

IN the estimation of the total carbon in iron, the metal is decomposed by copper ammonium chloride solution, and the deposited copper dissolved in the excess of the solution.

Hitherto, either a glass rod or a mechanical stirrer has been used for bringing fresh portions of the solution into contact with the metal, but both of these are open to objection. The author recommends agitation by a current of air, washed with lead acetate solution to free it from sulphuretted hydrogen and particles of dust, &c. The air is drawn through the system of bottles or flasks by means of a Bunsen water filter-pump. The iron borings and acidified copper solution (Langley, Chem. News, 69, 4) are placed in the flasks. When the pump is started, there is a continual passage of air through the series, which keeps the solution in constant motion. With this apparatus, there is no grinding of the carbonaceous residue, which largely retains the shape of the borings, and thus can be easily washed from the flask, and has no tendency to run through the filter, as would be the case with mechanical stirring with hard substances.—A. S.

INORGANIC CHEMISTRY.—QUALITATIVE.

Iodine, Detection of Traces of, in Presence of Bromine and Chlorine, by means of Ozonised Aldehydes. E. Ludwig. Ber. 1896, 29, 1451—1456.

The author finds that all the known aldehydes possess (like turpentine, for example) the power of absorbing and retaining oxygen in an active or ozonised condition, in which state they are able to liberate iodine, even from very dilute solutions of potassium iodide (1:600,000), and constitute a delicate test for that halogen. The solution (aqueous) to be examined, should be neutral, free from reducing bodies and salts of mercury, and should not be too highly charged with salts of the heavy metals; and only 2—5 drops of aldehyde should be added in order to avoid reabsorption of the liberated iodine. The latter may be rendered visible by addition of starch-paste, or preferably by extraction with carbon bisulphide. The presence of 1/50,000th of potassium iodide in a saturated solution of potassium bromide, is clearly indicated by the above means, although its presence is not revealed by the usual nitrous acid test. The preparation of ozonised aldehydes is a simple matter. In the case of acetaldehyde, a few cubic centimetres may be exposed to the air in a large flask for an hour. Paraldehyde, propionic aldehyde, methyl-propionic aldehyde, and phenyl-formaldehyde should be distilled (in small quantities) in a current of air; or, with the two last named, it suffices to boil a small quantity in a test-tube. Ozonised aldehydes retain their activity for a considerable time (except methyl-propionic aldehyde), but gradually become inert in presence of water. For quantitative purposes, paraldehyde would appear to be useful. A solution of potassium iodide (2 grms.) in water (100 c.c.), when distilled with paraldehyde (6 grms.), a current of air being drawn through the apparatus towards the end, was found to be quite free from iodine. The residue in the retort consisted of potassium acetate.—H. T. P.

INORGANIC CHEMISTRY.— QUANTITATIVE.

Carbonic Oxide in the Air, The Detection and Estimation of. F. Clowes. British Assoc., Chem. Sect., 1896.

CARBONIC oxide gas, when mingled with air in suitable proportion and fired, produces explosion. But a far greater danger arises from its poisonous nature when breathed. As small a proportion as 0.2 per cent. in air produces poisonous symptoms in man. This gas is introduced into the air by leakage of unburnt water-gas and other gaseous fuels, amongst which ordinary coal-gas must be included. It is produced in the coal-mine by the firing of certain explosives, such as blasting powder and the nitro-cottons; also during an explosion of fire-damp, and by burning of coal or gob-fire. Hence carbonic oxide may be frequently encountered in air, and since it cannot be smelt or detected by any ordinary tests, it is important to make known recently devised methods for detecting and estimating the gas.

Dr. Haldane has brought forward a method which depends upon the change in colour produced in diluted blood when it is shaken up with the gas. This is probably

the most delicate and accurate method known. But it requires some time for its performance, and good daylight is an absolute necessity.

Other methods are well known to the chemist which are not sufficiently delicate, and require to be carried out in a chemical laboratory.

The author recommends the flame-cap test as being at once quick of execution, sufficiently delicate, and also wide in its range of indications. The standard hydrogen flame, 0.4 in. in height, gives a cap 0.5 in. in height in air containing 0.25 per cent. of carbonic oxide, and the height of the cap increases as the percentage of carbonic oxide in the air becomes larger. The only drawback of the method consists in the fact that all combustible gases give flame-caps, and these are indistinguishable from that furnished by carbonic oxide. Hence the flame-cap test is only suitable when other combustible gases are known to be absent.

The test may be made by introducing into the air to be examined a hydrogen safety-lamp, such as has been now adopted in delicate tests for fire-damp and coal-gas. Since, however, there might be serious risk involved in entering and breathing the atmosphere, it is preferable to collect a sample of the air and pass it over the flame, as is done by Mr. Redwood in testing for petroleum vapour. A still more simple plan will often consist in pumping the air to be tested over the standard hydrogen flame in a suitable apparatus, such as was exhibited by the writer. It consists of a small metal cylinder with glass front, within which the hydrogen flame burns, being fed from a pocket cylinder of the compressed gas. The cylinder containing the flame is mounted on a folding portable camera tripod. The air to be tested is drawn through a long rubber tube, by working a valved rubber ball by the hand, and is made to pass over the hydrogen flame. A black cloth is thrown over the observer's head and the flame-cylinder, so as to enable the flame-cap to be accurately observed in darkness, and the height of the cap is registered by shifting a bent wire, moving stiffly in a stuffing box, until it just touches the tip of the cap. On removing the black cloth, the percentage of carbonic oxide is then at once read off upon a scale on the cylinder, the number standing opposite to the top of the movable wire.

The flame-cap test applied in this way presents the advantage of being rapid and delicate, and may be applied without any risk to the operator.

Oxygen by Absorption, The Accurate Determination of, with Alkaline Pyrogallol Solution. F. Clowes. Brit. Assoc., Chem. Sect., 1896.

It was found repeatedly in the author's laboratory that during the absorption of oxygen from the Brin gas, a considerable volume of carbon monoxide was evolved, although this did not occur in absorbing oxygen from the air. If the evolution of the gas was known to take place, and the carbon monoxide was subsequently absorbed by cuprous chloride solution before reading off the residual nitrogen, the estimation of the volume of oxygen was correct; if this precaution was not taken, the estimation was open to serious error. Repeated trials with varying proportions of pyrogallol and potassium hydrate showed that the evolution of carbon monoxide might be entirely prevented by using a sufficiently large excess of potassium hydrate. With the following proportions no fear of this source of error need be felt, even when pure oxygen is being absorbed:—160 grms. of potassium hydrate and 10 grms. of pyrogallol in 200 c.c. of solution. This solution is prepared by dissolving 160 grms. of potassium hydrate in 130 c.c. of water and then dissolving the 10 grms. of pyrogallol in the alkaline solution.

Boric Acid, Volumetric Determination of. M. Honig and G. Spitz. Zeits. für ang. Chem. 1896, 549—552.

Two methods are described:—

1. (a.) *Boric Acid (and Total Alkali) in Alkaline Borates.*—About 30 grms. of the sample are dissolved in water up to 1,000 c.c., and 50 c.c. of the solution exactly neutralised with $\frac{1}{2}$ N HCl, and methyl orange as indicator. The total alkali is thus found. To the solution, which now contains the boric acid in the free state, a few drops of phenolphthalein and 50 c.c. of glycerin are added, and

titration continued with $\frac{1}{2}N$ NaHO (perfectly free from CO_2) until the colour changes. If now a further quantity of glycerin be added, the solution will, as a rule, again become colourless; and it is necessary to continue adding alkali and glycerin (10 c.c. at a time) alternately until the red tint is no longer discharged. Under these conditions, the end-reaction is quite sharp, and the volume of alkali consumed, accords with the equation $B_2O_3 = 2NaHO$, i.e., 1 c.c. of $\frac{1}{2}N$ alkali = 0.0175 grm. B_2O_3 .

If the sample contain carbonates, the solution, after neutralisation with HCl, and prior to titration of the B_2O_3 , must be boiled under an inverted condenser to expel CO_2 . The latter, if desired, may be collected and determined by any suitable method.

(b.) *Boric Acid in Borates insoluble in Water (Boracite, &c.).*—2 grms. of the sample are boiled with a measured excess of $\frac{1}{2}N$ HCl (50 c.c.) under an inverted condenser until solution is effected and CO_2 expelled. The solution is allowed to cool, neutralised with $\frac{1}{2}N$ NaHO and methyl orange, and the boric acid finally titrated as under I. (a).

(c.) *Boric Acid in Mineral Silicates, Glass, &c.*—The finely-powdered substance is fused with sodium and potassium carbonates, the mass dissolved in water, boiled with a slight excess of ammonium chloride, and finally treated with ammoniacal zinc hydrate solution to get rid of the remaining traces of silica. The filtrate from the latter is concentrated to a small bulk, boiled with a slight excess of HCl to eliminate CO_2 , finally exactly neutralised (methyl orange), and treated as described under I. (a).

II. This method depends on the fact that the borax present in a solution may be measured by the quantity of ammonia evolved on distillation with ammonium chloride ($Na_2B_4O_7 = 2H_2O_3 = 2NH_3$). Alkaline carbonates, if present, must be destroyed, which may be effected by precipitation with silver nitrate in presence of ammonium nitrate. In the case of insoluble borates the finely-powdered substance (15 grms.), is boiled for 1 hour with a solution of sodium bicarbonate (10 grms.), a stream of CO_2 being passed through the liquid during the operation. By this means the boric acid is extracted, and passes into solution as borax. The liquid is then diluted to 500 c.c. and filtered. To 100 c.c. of the filtrate are added 4–5 grms. of ammonium nitrate, and then 10 per cent. solution of silver nitrate so long as a precipitate forms (about 60 c.c.). The whole is then diluted to 300 c.c., mixed, immediately filtered, and 200 c.c. of the filtrate distilled with about 2 grms. of ammonium chloride, the ammonia set free being received in standard acid in the usual way. 1 c.c. of N acid = 0.070 grm. B_2O_3 . Test analyses, by both methods, yielded highly satisfactory results.—H. T. P.

Alkali and Vitriol Works, Analytical Methods for. P. Dobriner and W. Schranz. Zeits. f. ang. Chem. 1896, 453–456.

I. *Estimation of Free Sulphuric Anhydride in Fuming Vitriol.*—The authors propose a modification of the existing process with a view to eliminate the ordinary sources of error due to the use of too little substance, errors in reading the burette, and alterations in the standard solutions due to changes in temperature.

The open end of a test tube is drawn out to a fine point and the tube is then weighed. From 6 to 8 grms. of the vitriol are filled into this by placing its pointed end in the acid and warming the wider portion, and, after sealing off the tip and drying the outside, the tube is again weighed. It is broken in 150 c.c. of water contained in a strong stoppered bottle and so much pure sodium carbonate added that after boiling to remove the carbonic acid, from 3 to 4 c.c. of normal acid are required to render the solution neutral. The indicator used is phenolphthalein. If A per cent. represents the total acidity, calculated as SO_3 , the percentage of free anhydride, in the absence of sulphurous acid, is obtained by using the formula—

$$\frac{49}{9} A - 444.44.$$

II. *Estimation of Caustic Soda.*—The two methods in use (a) Determination of alkalinity before and after precipitation of the carbonic acid by barium chloride, and (b)

Estimation of the alkalinity and carbonic acid as such, are found to give identical results if a quantitative filter paper be used to filter off the barium carbonate. If hardened plaited filters are used, the results may come out 1 to 2 per cent. too low by method (a), owing to the absorption of alkali by the paper.

Sufficiently accurate results are obtained by using phenolphthalein as indicator and titrating with normal acid until the colour vanishes, then adding a slight excess of acid and, after boiling, titrating back with normal alkali.

III.—*Estimation of Sodium Sulphide and Sodium Sulphydrate.*—Sodium sulphydrate is obtained by the action of sulphuretted hydrogen on sodium sulphide.

and, on the other hand, sodium sulphydrate is reconverted into sodium sulphide under the influence of caustic soda.

For this reason sodium sulphide, sulphydrate, and caustic soda cannot exist in the same solution, and the analysis resolves itself into (a) the estimation of sodium sulphide in presence of sulphydrate, or (b) the estimation of sodium sulphide in presence of caustic soda.

(a.) 12 grms. of the substance are dissolved and made up to 1 litre with water. 25 c.c. of this solution are run from a burette into about 15 c.c. (or less if the yellow colour does not vanish), $\frac{1}{20}$ normal iodine solution, rendered acid with 10 c.c. of normal sulphuric acid and diluted to about 150 c.c. with water, and, after addition of starch solution, the excess of free hydrogen sulphide is titrated back with iodine. The c.c. of iodine used $\times 2$ give the percentage of $Na_2S + 9H_2O = A$ per cent.; this is equivalent to $\frac{34}{210} A$ per cent. of total SH_2 in the substance.

The alkali is obtained by dissolving 6 grms. of the product in water, boiling with excess of normal sulphuric acid, and titrating back this excess with normal alkali. The sodium sulphide (= B per cent.) is got by multiplying the acid actually used by 2; the sulphuretted hydrogen bound to sodium is therefore $\frac{34}{210} B$.

From these values we obtain in the substance B per cent. sodium sulphide and $\frac{34}{210} (A - B)$ per cent. free hydrogen sulphide. This mixture, according to equation (1), corresponds to $(2B - A)$ per cent. of $Na_2S.9H_2O$ and $\frac{7}{15} (A - B)$ per cent. of NaSH.

(b.) The titrations for sulphuretted hydrogen and caustic soda are made as above, giving respectively, when calculated to sodium sulphide, U per cent. $Na_2S.9H_2O$, and V per cent. $Na_2S.9H_2O$. From equation (2) it is seen that the mixture consists of U per cent. $Na_2S.9H_2O$, and $\frac{1}{2} (V - U)$ per cent. of NaOH.

In this process the presence of polysulphides and sulphites is not taken into account.—J. T. C.

Nitrites, A New Reagent for the Detection and Estimation of. M. C. Schuyten. Chem. Zeit. 1896, 20, [75], 722–723.

One part of antipyrine is dissolved in 10 parts of 10 per cent. acetic acid, and 5 c.c. of the solution mixed with an equal volume of the liquid to be tested. If nitrites are present, a permanent green colour appears within a minute and is distinctly perceptible for 1 part of nitrite in 20,000 of water. Alkalis, chlorides, organic bodies such as sugar, alcohol, and phenol, are, if not too concentrated, without appreciable influence. Oxidising substances destroy the colour, hydrochloric and sulphuric acids change it into a yellow. For quantitative purposes colorimetric standard solutions are prepared, in which the amount of nitrite varies from 1 part in 1,000–20,000 parts of water respectively.—J. L. B.

Insoluble Phosphorus in Iron Ores. C. T. Mixer. Eng. and Mining J., July 4, 1896.

The present method of estimating the insoluble phosphorus in iron ores is very objectionable owing to the time and patience required in the fusion of the siliceous residue with

carbonate of soda. The author discovered by experiment, that the phosphorus is rendered soluble by simply calcining the siliceous residue. The following method is given:—The ore is dissolved in the usual manner in hydrochloric acid, filtered into the precipitation flasks, and the paper and residue put into a platinum crucible for ignition. When the paper is burned off, the residue is broken up with a platinum rod is calcined at a red heat a couple of minutes longer, when it is removed and placed in a beaker. A little water is added and 5 or 6 drops of hydrochloric or nitric acid and the solution is gently boiled for 3–5 minutes, after which it is filtered and is then ready for precipitation with ammonium molybdate. The method is said to give practically the same results as the one now in use.—A. S.

Thomas Slag, Citrate Solubility of. H. Dabbers. *Zeits. f. aug. Chem.* 1896, 468–473.

From his investigations the author comes to the conclusion that concordant results can only be obtained by long continued shaking of the sample with an excess of acid ammonium citrate solution. This treatment is especially necessary with strongly basic slags, if the analytical differences are not to exceed the limit of 0.75 per cent. of P_2O_5 .—J. T. C.

Palladium: Its Separation from Platinum. Cohn and Fleissner. *Monatsh. f. Chem.* 17, 361–364.

THE determination of palladium by precipitation with mercuric cyanide cannot be carried out in presence of copper, whilst its determination (and in small quantities even its detection) as iodide is vitiated by the solubility of the iodide in excess of potassium iodide solution.

The method proposed depends on the different solubilities of ammonium platinchloride, palladiochloride, and palladiochloride, and is carried out as follows: The aqua regia solution of the two metals is freed from nitric acid by repeated evaporation, 10 cc. of a 10 per cent. solution of ammonium chloride added, and the whole taken nearly to dryness on the water-bath. To the residue a few drops of water are added and then excess of 30 per cent. ammonium chloride solution. After standing awhile, the precipitate of $(NH_4)_2PtCl_6$ is filtered off, washed first with ammonium chloride solution, and afterwards with alcohol (the first washings being added to the filtrate), placed with the filter, while still damp, in a porcelain crucible, and incinerated. The filtrate, containing the palladium as $(NH_4)_2PtCl_6$, is slowly evaporated down with sufficient nitric acid; after some time, the bright red crystalline precipitate of $(NH_4)_2PtCl_6$ is filtered off, washed with strong ammonium chloride containing a little nitric acid, and incinerated like the platinum salt. If the resulting palladium is bluish through imperfect reduction, a few moments' heating while coal-gas is directed into the crucible, will complete the reduction.

A series of experiments with known mixtures of the two metals showed the method to be accurate, whatever the relative proportions of the two. The method, too, is clearly unaffected by the presence of other metals, such as iron or copper.—J. T. D.

Quantitative Analysis by Electrolysis. M. Heidenreich. *Ber.* 1896, 29, 1585–1590.

THE author investigates, as to their trustworthiness, some of the published methods for the electrolytic determination of metals (see also this Journal, 1896, 378). In his experiments, roughened (sand-blasted) platinum capsules, and circular, flat anodes—as recommended by Classen—were used. In all cases the volume of the electrolyte was 120 c.c. The currents are expressed in amperes per 100 sq. cm. (ND_{100}).

Iron (*Zeits. Analyt. Chem.* 28, 342).—From a solution containing sodium citrate and free citric acid, iron is deposited, partly metallic, partly dull in appearance, and contains occluded carbon. The results obtained are, on this account, somewhat high. The same difficulty occurs when ferric oxalate is electrolysed.

Copper (*Amer. Chem. J.* 12, 213).—A spongy deposit, unfit for weighing, is obtained from a solution containing sodium phosphate and phosphoric acid.

Cadmium (*Ber.* 11, 2048).—Unsatisfactory results were obtained from solutions containing—(1.) Normal acetate; (2.) The same plus acetic acid; (3.) Sodium phosphate and phosphoric acid.

Silver (*Amer. Chem. J.* 12, Smith).—The deposit is spongy from an ammoniacal sodium phosphate solution.

Molybdenum (*Ber.* 11, 2048).—From a solution of ammonium molybdate, the separation of molybdenum (as sesquihydrate) is not complete, even after 2–4 days; moreover, during ignition of the sesquihydrate—prior to weighing—a little is apt to volatilise.

Uranium (*Amer. Chem. J.* 1, 329).—Electrolysis of the acetate yielded unsatisfactory results.

Separations.—Lead from Mercury (*Zeits. anorg. Chem.* 4, 267).—Fair results are obtained if the solution contain free nitric acid, 20–30 c.c. of HNO_3 (sp. gr. 1.3–1.4); current strength, $ND_{100} = 0.2–0.5$ ampere.

Silver from Lead (*ibid.*, 268).—In presence of free nitric acid, a spongy deposit of silver is obtained.

Copper from Zinc (*ibid.*, 269).—In an acid solution (1 c.c. of HNO_3 , sp. gr. 1.4) very good results are obtained, providing the E.M.F. be not allowed to exceed 1.4 volts. The bulk of the copper is rapidly deposited (current = 0.2 ampere); but the separation requires for its completion 18–20 hours.

Copper from Cadmium (*ibid.*, 268).—A nitric acid solution proved unsatisfactory. Better results were obtained in presence of free sulphuric acid (15 c.c. of H_2SO_4 , sp. gr. 1.09). The E.M.F. must not exceed 1.85 volts. Time required, 24 hours; current, 0.03–0.07 ampere.

Silver from Copper (*Zeits. f. Elektrochem.* 2, 312).—The solution employed contained KCN, 2 grms.; $AgNO_3$, 0.25 grm.; $CuSO_4 \cdot 5H_2O$, 0.75 grm.; current strength, 0.03–0.10 ampere; E.M.F., 1–1.4 volts; time required, 6–8 hours. The results are very good. By warming the solution to 65–70° C. during electrolysis, the time of deposition may be, however, materially shortened.

Silver from Zinc.—A double cyanide solution (KCN, 2.5 grms.; $AgNO_3$, 0.3–0.4 grm.; $ZnSO_4 \cdot 7H_2O$, 1.0 grm.) yielded good results. E.M.F., 2 volts; current, 0.05 ampere; time required, 15–22 hours, or 6 hours when working at 60°–70° C.

Mercury from Zinc.—Good results are obtained from a cyanide bath (KCN, 2–3 grms.; $HgCl_2$, 0.25 grm.; $ZnSO_4 \cdot 7H_2O$, 1 grm.), but the platinum vessels are strongly attacked. E.M.F., 1.6–1.7 volts; current, 0.03–0.08 ampere; time, 14 hours.

Mercury from Nickel.—The solution as in previous separation, but containing nickel ammonium sulphate instead of zinc sulphate. E.M.F., 1.2–1.6 volts; current, 0.05–0.09 ampere; time, 5–12 hours; results, good.

—H. T. P.

ORGANIC CHEMISTRY.—QUALITATIVE.

Pentoses, Detection of, Improved Method of Applying the Phloroglucinol Test. B. Tollens. *Ber.* 1896, 29, 1202–1209.

AS is well-known, solutions of pentoses, when heated with hydrochloric acid and phloroglucinol, develop a cherry-red coloration and exhibit a characteristic absorption spectrum. In presence of impurities (sugars, &c.), however, also yielding coloured decomposition products, the pentose reaction may be partially or completely obscured. In such cases the author finds it practicable to purify the red colouring matter (which separates out on cooling) by washing, and subsequently to examine its alcoholic solution, when, in presence of pentoses, the characteristic absorption spectrum becomes clearly visible. (A dark band extending from D to E, and a fainter band in the violet, the intermediate blue-green region being comparatively bright.) The details are as follows:—5 c.c. of the liquid under examination, contained in a test-tube, are treated with 5 c.c. of HCl (sp. gr. 1.19) and 20–30 mgrms. of phloroglucinol. The mixture is gently heated, and immediately viewed by the spectroscope. If no indication be obtained, the solution is heated nearly to boiling, and after 2–3 minutes, cooled, filtered through a wet paper, and the precipitate washed 2–3 times with water. The residue (violet-coloured in

presence of pentose, galactose, &c.) is then dissolved in 93 per cent. alcohol, and the solution examined. The principal sugars yield, with phloroglucinol, brownish or yellowish solutions, and, in some cases, a violet precipitate; but in no case does the alcoholic solution exhibit any trace of absorption bands. Solutions of xylose or arabinose (1:500) in urine, which gave no direct indications, still afforded a distinct absorption spectrum when examined as above, the limit of sensitiveness being attained at a dilution of 1:1000 to 2000. In presence of dextrose, &c., however, the reaction is somewhat less delicate. The author shows that the common wines (clarks and Rhine wines) frequently contain pentoses, to the presence of which, rather than to traces of unfermented levulose, the "residual" reducing power of wine must, perhaps, be ascribed.—H. T. P.

Milk, Estimation of the Freezing Point of, as a Means of Detecting and Quantitatively Estimating Dilution with Water. H. J. Hamburger. *Nederl. Tijdschr. Pharm.* 8, 209—215.

The freezing point of pure cow's milk apparently fluctuates within very small limits, namely, according to the author's experience, between 0.556° and 0.575° below 0° C., the average being 0.561°.

By a determination of the freezing point, an addition of water may be detected and quantitatively estimated with great accuracy, as is shown by the following table:—

	Observed lowering of the Freezing Point.	Added Quantity of Water, calculated from the lowering of the Freezing Point in comparison with that of whole Milk.	Added Quantity of Water, calculated on the average lowering of the Freezing Point of whole Milk = - 0.561° C.	
				Per Cent.
Whole milk.....	-0.558			Per Cent.
" + 5% H ₂ O	-0.532	4.7	5.0	
" + 10 "	-0.506	10.5	10.9	
" + 15 "	-0.476	14.7	15.1	
" + 20 "	-0.445	20.5	20.7	
" + 25 "	-0.413	25.9	26.4	

—A. S.

Milk, Congealing Point of. Borda and Génin. *Comptes rend.* 1896, 123, 125—127.

The authors have determined the congealing point of 50 samples of cows' milk, and they find that the temperature is by no means constant, but varies between - 0.44° and - 0.56° with different samples. In the case of why the differences are greater still. These results lead to the conclusion that the determination of the congealing point does not constitute a satisfactory method for detecting the watering of milk. It gives, in their opinion, no more information than the density, whilst the latter is more readily determined.—A. K. M.

Aconitine, A Test for. *J. Pharm. Chim.* 1896, 4, 266.

On adding to a solution of aconitine a slight excess of potassium permanganate a violet, crystalline precipitate is produced. The presence of 0.000025 grm. may be detected by this reaction. Cocaine, hydrastinine, and papaverine also give precipitates with the same reagent, but they are distinguished by their colour from that produced by aconitine.—A. C. W.

Eucaine Hydrochloride, To distinguish; from Cocaine. *Bull. Gén. de Thérap. Sec. Pharm.* 1, 499.

35 c.c. of a solution of eucaine hydrochloride, gives, with three drops of 5 per cent. chromic acid solution, an immediate citron-yellow, distinctly crystalline precipitate. Hydrochloride of cocaine under similar conditions gives no precipitate. The addition of 3 c.c. of 10 per cent. potassium iodide solution to 5 c.c. of 1 per cent. solution of eucaine hydrochloride causes a milky appearance, and if left for a

time the whole solution becomes converted into a crystalline paste, due to the formation of colourless scales of eucaine hydriodide. Solutions of cocaine hydrochloride are not affected under the same conditions. The solubility of cocaine and eucaine hydrochlorides are widely different. Of the former, 1 part dissolves in 0.75 parts of water at 15° C., whilst 1 part of the latter requires about 10 parts of water. (See this Journal, 1896, 679.)—A. S.

Alloxantin from Convicin obtained from Broad Beans and Felches, reactions of. H. Ritthausen. *Ber.* 1896, 29, 2106.

FURTHER reactions proving the identity of alloxantin prepared from convicin and that obtained from uric acid (see this Journal, 1896, 169) are: (1.) The formation of murexide on evaporating its ammoniacal solution. (2.) The formation of uramil by boiling it with ammonium chloride. (3.) The formation of iso-uric acid by heating it with cyanamide. This is of some interest as proving the occurrence of derivatives of uric acid in the seeds of plants.

Bergamot Oil, Proof of the Purity of. A. Borntraeger. *Zeits. Anal. Chem.* 1896, 35, 523.

See under XX., page 739.

ORGANIC CHEMISTRY.—QUANTITATIVE.

Ethylene, Estimation of, in Gaseous Mixtures. P. Fritzsche. *Zeits. f. ang. Chem.* 1896, 456—459.

The earlier methods of estimating ethylene when admixed with other gases are neither simple nor satisfactory; a combustion requires too much time, whilst absorption with fuming sulphuric acid or bromine gives respectively the total heavy hydrocarbons or the unsaturated compounds which are present and not the ethylene alone.

The author bases his method upon the absorption of ethylene by means of sulphuric acid, and the subsequent splitting up of the ethylsulphuric acid thus formed into sulphuric acid and alcohol, the amount of which latter compound can be estimated.

The reaction is quantitative and for gases rich in ethylene no difficulties are to be feared. The following mode of procedure is recommended.

The gas, freed from tar, ammonia, and sulphuretted hydrogen, is made to fill a glass cylinder fitted at both ends with glass taps and of from 200—300 c.c. capacity. Sufficient concentrated sulphuric acid for easy agitation is now admitted into the tube and shaking continued until, on carefully opening one of the taps, no more air enters the apparatus. The acid is now drained out and the apparatus washed with a small quantity of water (not more than twice the weight of sulphuric acid used) and the acid and washings distilled. To this distillate a small quantity of soda is added and it is then re-distilled till two-thirds of its bulk have passed over. The absolute weight and specific gravity of this second distillate are determined and the quantity of alcohol calculated from Mendeleeff's figures. The best results are obtained when the alcoholic content lies between 1 and 2 per cent.

For coal-gas, &c. the method is not so simple owing to the small quantity of ethylene present. To avoid the necessity of using large volumes of sulphuric acid for absorption the author carries out the experiment at 100° C., at which temperature combination occurs more rapidly, and only employs sufficient acid to moisten the walls of the slowly rotating gas vessel. At 100° C. the time required for complete absorption is about four hours, whilst, working at ordinary temperature, the reaction is not finished after 20 hours. The ethyl sulphuric acid obtained, is diluted and distilled as before, and the successive distillates redistilled four or five times, until a final solution is obtained sufficiently rich in alcohol for a correct specific gravity determination. For coal-gas, the absorption vessel should be 500 mm. long and 110 to 120 mm. in diameter; the concentrated acid used should be about 20 c.c., and the wash-water about 40 c.c.

The butylene may be removed from the gas before filling the tube by passing the gas through a wash-bottle

moistened with 70 per cent. H_2SO_4 —any propylene present is estimated as ethylene.

Trials of a volumetric method dependent on the splitting up of barium ethyl sulphate in concentrated solution into alcohol, barium sulphate, and free sulphuric acid did not lead to satisfactory results. The reason of this, according to the author, is that the ethylene absorbed, exists partially as ethyl sulphuric acid, and also partially as alcohol, in the sulphuric acid solution.—J. T. C.

Thiophene in Benzol, Rapid Volumetric Estimation of.
G. Denigès, Bull. Soc. Chim. 15, 1896, 1064—1065.

This is a development of the method already given (Bull. Soc. Chim. 13, 1895, 537; this Journal, 1895, 893, and Bull. Soc. Chim. 15, 1896, 862) and is carried out as follows:—Mix in a 60–90-c.c. flask, 2 c.c. of the benzol under examination with 30 c.c. of acetone-free methyl alcohol, and add quickly 10 c.c. of a solution of mercuric sulphate prepared by dissolving 50 grms. of red oxide of mercury in 200 c.c. of pure sulphuric acid and 1 litre of distilled water. Close the flask, shake and allow to stand for 20 minutes, and filter from the compound—

Of the filtrate carefully preserved from evaporation, 21 c.c., corresponding to 1 c.c. of benzol, are put into a litre flask together with 350 c.c. of water, 15 c.c. of ammonia, 10 c.c. of potassium cyanide solution (equivalent to $\frac{1}{10}$ N silver nitrate), and 5 or 6 drops of a 20 per cent. potassium iodide solution. The turbidity due to the separation of the benzol disappears on shaking or on slightly warming the solution, and decinormal silver nitrate is added to the clear liquid until a permanent opalescence is produced. If n be the number of c.c. of silver nitrate required, then the amount of thiophene x contained in a litre of the given benzol is $x = 2.8 (n - 0.3)$. If the benzol contain more than 25 grms. of thiophene per litre, only 1 c.c. should be taken for the test.—T. A. L.

Sugar, Estimation of, in the Beetroot. H. Pellet.

Rev. de Chim. Indust. 1896, 7, 233—237.

THE aqueous method of extraction is only adapted for material resulting from conical rasps. The normal or double the normal weight of pulp is placed in a suitable extractor, provided with a tap, and hot or cold water allowed to percolate slowly through the mass. The extract is received in a 200-c.c. flask, a few c.c. of basic lead acetate are added, and the whole made up to volume at the ordinary temperature. It is generally advisable to extract a second time.

The method of hot aqueous digestion is suited for the examination of fresh diffusion cosettes and of finely divided beetroot pulp. The normal or double the normal weight of pulp is introduced into a 200-c.c. flask of particular shape. 5 to 15 c.c. of basic lead acetate, and 180–190 c.c. of water are added, and the contents of the flask heated in a water bath from 80°–85° C. for 1 to 1½ hours, according to the quantity of pulp. The mixture is then cooled, made up to 200 c.c., filtered, and polarised.

In the rapid cold aqueous extraction, the normal weight is placed with water in a 200-c.c. flask. 5 to 8 c.c. of basic lead acetate are added, the contents made up to volume, then filtered and polarised in a 400-mm. tube.

Wojcieki's process consists in weighing out 26.048 grms. of fine pulp, and placing this amount in an ungraduated vessel of 150 c.c. capacity, provided with a tightly-fitting cover. 77 c.c. of water containing from 5 to 7 c.c. of basic lead acetate are added, then shaken, filtered, and polarised, after addition of one or two drops of acetic acid. Ledoete has modified and accelerated this method by using metal capsules provided with covers, into which the pulp is directly weighed. 177 c.c. of water containing basic lead acetate are delivered from a pipette; the mixture is well shaken, filtered, and polarised. In adding 77 or 177 c.c. of water, allowance is made for the average quantity of juice contained in beetroot pulp, and the volume is thereby at once adjusted to 100 or 200 c.c.—J. L. B.

Phosphoric Acid, Estimation of, in Medicinal Wines.

F. Glaser and K. Mühle. Chem. Zeit. 1896, 20, 723.

100 c.c. of the wine are placed in a 250-c.c. flask, and evaporated over wire gauze to a syrupy consistency. It is allowed to cool, 25 c.c. of strong nitric acid added, and heated with a small flame until the reaction sets in, which then continues without further warming. When the evolution of gas has ceased, 75 c.c. of strong nitric acid are added, and the mixture is heated as before; the evaporation proceeds rapidly nearly to dryness without explosive violence or spitting. 10 c.c. of concentrated sulphuric acid and a small quantity of mercury are added to the cooled liquid in the flask; on warming, the clear liquid is darkened by the carbonisation of incompletely decomposed organic matter, and, if necessary, the oxidation may be hastened by heating with a fuller flame. After a few minutes, the decomposition of the organic matter is completed—a stage indicated by the clear colour of the liquid; it is cooled, the flask filled up to volume, filtered, and 100 c.c. of the filtrate (= 40 c.c. of wine) neutralised with ammonia before determining the phosphoric acid by the molybdenum or citrate method.

The decomposition can also be effected by concentrated sulphuric acid and mercury, or sulphate of copper; the method is, however, slower, as the sulphuric acid occasions a puffing-up of the charred sugar.—J. L. B.

Cheese, Chemical Investigation of, Composition of.

A. Stutzer. Zeits. anal. Chem. 1896, 35, 493.

1. *The Total Nitrogen* was determined by Kjeldahl's method in 10 grms. of a mixture of 100 grms. of cheese and 400 grms. of washed, ignited, and sieved sand.

2. *Nitrogen as Ammonium Salts* was determined by distilling a quantity of the sand mixture, containing 5 grms. of cheese, with 200 c.c. of water and barium carbonate. If magnesia or magnesium carbonate (which usually contains some oxide) be used in this process too high results are obtained, because of the partial decomposition of amides.

3. *The Nitrogen in the Form of Amides* is obtained by shaking the same amount of the sand mixture with 150 c.c. of water for 15 minutes, allowing to stand 15 hours, adding 100 c.c. dilute sulphuric acid, and then phosphotungstic acid so long as a precipitate appears. The precipitate is washed with dilute sulphuric acid until the filtrate amounts to 500 c.c., in 200 c.c. of which the nitrogen is determined, by subtracting from this the nitrogen found as ammonium salts, that present as amides is obtained. Copper hydroxide is not adapted to the separation of albumins when pancreaspeptone (the peptone of Kühn) is present, since this is only partially thrown down. Phosphotungstic acid serves to separate casein, albumin, albumoses, and pancreaspeptone from the worthless tyrosin, leucin, and other amides, and from the ammonium salts.

4. *Indigestible Nitrogenous Substances.*—The mucous membrane of several fresh pigs' stomachs was cut into small pieces, placed in a flask, and for every stomach 5 litres of water, 100 c.c. of a hydrochloric acid containing 10 grms. of acid, and 2.5 grms. of thymol dissolved in alcohol were added. After standing 24 hours, with occasional shaking, the mixture was filtered in turn through flannel, coarse, and fine filter paper. If necessary, after titration, so much hydrochloric acid was added that the liquid contained exactly 0.2 per cent. Gastric juice thus prepared keeps for months unaltered.

A quantity of the sand mixture containing 5 grms. of cheese was extracted with ether, then 500 c.c. of gastric juice added, and the mixture warmed 48 hours in a thermostat at 37°–40° C. At intervals of about 2 hours, 5 c.c. of a 10 per cent. hydrochloric acid solution were added until the acid amounted to 1 per cent. After filtering, the nitrogen was determined in the washed residue. According to Kühn, treatment with pancreatic extract can be avoided by digestion for at least 48 hours.

5. *Nitrogen as Albumoses and Peptones.*—The same amount of the sand mixture was heated to boiling with 100 c.c. of water, and the liquid poured off into a 500-c.c. flask. The extraction was repeated until the flask was nearly full, then, after cooling, making up to the mark and filtering, 200 c.c. of the filtrate were precipitated with

the solution, made neutral or feebly alkaline (under these conditions proteins remain in solution), is precipitated with an iodine solution saturated with potassium iodide, after standing, the liquid is filtered through an asbestos filter, the precipitate washed with cold water and dissolved in pure acetone. The dark brown solution is made alkaline, and then acid, and mixed with water; it then contains the alkaloid as acid salt. The acetone is driven off by a gentle heat on the water-bath, the liquid decolorised by a few drops of thiosulphate, and after addition of sodium carbonate in excess, the alkaloid is extracted by shaking with chloroform. In the case of morphine and narcotine the extraction is different (amyl alcohol or chloroform from an ammoniacal liquid or chloroform containing alcohol from a sodium carbonate solution). (Glicosides do not give a reaction with solution of iodine in potassium iodide. The method for obtaining alkaloids from plant extracts is quite similar, except that after acidifying the acetone solution of the periodide and adding water, it is immediately shaken with petroleum ether of boiling point 30° — 50° C.; this extracts most of the acetone and also impurities possibly present; this extraction is repeated, and the ether washed with a little acidified water. The alkaloid solution is then warmed on the water-bath, thiosulphate added, after cooling, and the extraction with chloroform takes place as before.

Generally, in heating to drive off the solvent before weighing, the alkaloid becomes brown; this is avoided in the presence of alkalis. The use of ammonia to precipitate the base is not advisable, for, though soluble in ether, it is volatile. The author adds ether which has been shaken with aqueous sodium carbonate (very slightly soluble in ether) to the solvent used; thus the browning is prevented, the error introduced is negligible in view of the varying amounts of water of crystallisation contained in the alkaloids.

The method of isolating pure alkaloids by addition of acid to their ethereal solutions is objectionable, generally because this will also precipitate salts of amide bases, and particularly objectionable when ammonia has been used to separate the free alkaloid.

A Morphine Reaction.—On addition of potassium iodide solution of iodine to an alkaline hydroxide morphine solution, there is obtained at first a yellow coloration, which, by a very gradual addition of iodine, turns to a grass green, the same coloration is given by bromine, but not chlorine. Apomorphine does not give this reaction, nor do codeine and other alkaloids; it is possibly due to an oxidising action of iodine.—A. C. W.

Theobromine, Determination of, in Cacao. Eminger.
Forschungsberichte, 1896, 275.

The author first extracts vegetable fat by digesting 10 grms. of the finely-powdered material with 150 parts of petroleum spirit; the residue is then dried, and a weighed portion boiled for about half an hour, or until the formation of cacao-red is completed, with 100 c.c. of dilute sulphuric acid (3—4 per cent.) in a flask fitted with a reflux condenser. The contents of the flask are then turned into a beaker, and, whilst hot, exactly neutralised with the calculated quantity of baryta; the whole is evaporated to dryness with some sand, and the residue extracted in a Soxhlet apparatus, with 150 parts of chloroform, for five hours; the chloroform is then distilled off, and the residue dried at 100° C. This residue is then washed with not more than 100 c.c. of carbon tetrachloride, which dissolves the fat and caffeine; the theobromine, being quite insoluble in carbon tetrachloride at 18° C., is collected on a filter, dissolved in boiling water, the solution filtered and evaporated, and the residue weighed. By this method the theobromine in different kinds of cacao was found to vary from 1.05 to 2.34 per cent., and the caffeine from 0.05 to 0.36 per cent. Theobromine is soluble in 736.5 parts of water at 18° C., in 135 parts at 100° C.; in 818 parts of boiling absolute alcohol; in 21,000 parts of ether at 17° C.; in 2,710 parts of boiling chloroform, and in 5,808 parts at 18° C. "Theobromine begins to sublime at 220° C. without melting, whilst caffeine sublimes at 180° C., and begins to melt at 220° C." Theobromine is more or less decomposed

if warmed for any length of time with alkalis, earthy oxides, or hydrated lead oxide.—A. S.

Chloroform, Analysis of. Gay. J. Pharm. Chim. 1896, 4, 259.

1. A piece of filter paper saturated with the chloroform should dry completely, and the odour remain pleasant to the end. The contrary indicates the presence of amyl alcohol.

2. Shake 6 c.c. with 3 c.c. of water and test with litmus paper; this should not be reddened.

3. Shake with an equal volume of 10 per cent. silver nitrate; a white precipitate on standing indicates the presence of hydrochloric acid, and a black precipitate on boiling, that of aldehyde or acetone.

4. To 5 c.c. add 2 c.c. of a solution of 1 part of potassium bichromate in 100 of parts strong sulphuric acid, and warm gently; if alcohol be present a green coloration appears. A quantitative test for alcohol is necessary, since 0.5 per cent. may be added to preserve the chloroform. To 5 c.c. add 1 c.c. of Mohr's solution (1 part of potassium permanganate and 10 parts of alcoholic potash dissolved in 25 parts of water) in such a manner that the liquids do not mix; then shake whilst slowly turning the tube, and observe the time between the mixture and appearance of a green colour.

Time: 5 minutes	Very pure chloroform.
" 2.5 "	0.01 per cent. alcohol.
" 35 seconds	0.1 " "
" 5 "	0.5 " "
" Less than 5 seconds ..	more than 0.5 " "
One agitation	1.0 " "

5. Shake violently 10 c.c. with an equal volume of strong sulphuric acid and let stand. The mixture remains colourless, even for an hour, if the product is pure, but if it becomes brown, the presence of chloro-derivatives of ethyl alcohol or of the higher homologues is indicated.—A. C. W.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Phenols which are Insoluble in Water, Action of the Oxidising Ferment of Mushrooms on. E. Bourquelot. Comptes rend. 1896, 123, 423—425.

SEE also this Journal, 1895, 683. In continuation of his experiments on the oxidising action of the ferment of mushrooms, the author now describes experiments with ortho-, meta-, and paraxylenol, with thymol, carvacrol, and α - and β -naphthol. He employs dilute alcohol as the solvent, and he shows that this substance neither interferes with the oxidising action of the ferment, nor becomes oxidised itself. In all cases the phenols underwent oxidation. In the case of α -naphthol, the solution became first violet, then blue, and finally deposited a dirty blue precipitate. The solution of β -naphthol, on the other hand, gave a white precipitate, which gradually became yellow; and this difference may be used to distinguish the two isomers.—A. K. M.

Acetylene: Is it an Electrolyte? G. Bredig and A. Usoff. Zeits. f. Elektrochemie, 1896, 3, 116—117.

H. C. Jones and C. R. Allen have published measurements of the molecular conductivity of aqueous solutions of acetylene, according to which its conductivity is about as great as that of an equivalent quantity of acetic acid. This

would indicate that in solution, acetylene suffers considerable electrolytic dissociation. As the acid character of acetylene rendered it likely that the carbon-anion C_2^- = (the existence of which has not yet been demonstrated) might make its appearance in fused or dissolved acetylene salts (carbides), the authors have studied the behaviour of acetylene and its salts (Ag_2C_2 , CuC_2 , &c.). They find that the determinations made by Jones and Allen are incorrect. The molecular conductivity of acetylene is exceedingly small; it is an exceptionally feeble electrolyte, and is therefore one of the weakest acids. Thus the salts of acetylene must be almost completely hydrolysed in aqueous solution, as, indeed, is shown by the action of water upon calcium carbide.

Ethylene oxide, like acetylene, occupies a position between electrolytes and non-electrolytes; its molecular conductivity is vanishingly small, and hence it must be regarded as a very weak base.—D. E. J.

Vicin, a Glucoside. H. Ritthausen. Ber. 1896, 29, 2108.

"VICIN," a substance prepared from broad beans and vetches by the author 20 years ago, was classified by Boilestein as an alkaloid. It appears, however, to be a glucoside, since by boiling it with dilute sulphuric acid a sugar is formed. After standing for several years, this crystallised, but could not be obtained sufficiently pure to be identified. Its reactions make it probable, however, that it is a mixture of glucose and galactose.—T. E.

New Books.

ROSCOE-SCHORLEMMER'S LEHRBUCH DER ANORGANISCHEN CHEMIE. VON SIR HENRY E. ROSCOE, LL.D., F.R.S., UND ALEXANDER CLASSEN, Ph.D. 2ter Band. 3te Gänzlich umgearbeitete und vermehrte Auflage. Erste Abtheilung. Friedr. Vieweg und Sohn, Braunschweig. 1896. Price 12s.

THIS is Part I. of the Second Volume of the third edition of the Roscoe-Schorlemmer Treatise on Inorganic Chemistry. This third edition is issued by Sir Henry Roscoe in conjunction with Professor A. Classen, of Aachen. It contains 432 pages of subject-matter, and, incomplete in itself, runs on to page 433, which will follow in the Second Part. The table of contents is given at the end of the uncompleted volume. The pages of Part I. are illustrated with 135 wood engravings, in most cases representing plant and apparatus employed in leading technical processes. The subjects treated of are chiefly the following:—Metals: Alkali Metals, Ammonium Compounds, Metals of the Alkaline Earths, and Magnesium. Metals of the Copper Group: Copper, Silver, Gold, and Aluminium. Alums: Phosphate and Silicate of Aluminium. Ultramarine, Glass, Porcelain, and Earthenware.

DETECTION AND ESTIMATION OF INFLAMMABLE GAS AND VAPOUR IN THE AIR. By FRANK CLOWES, D.Sc., and BOVERTON REDWOOD, F.R.S.E. Crosby, Lockwood, and Son, 7, Stationers' Hall Court, Ludgate Hill. 1896. Price 5s.

8vo volume, with frontispiece representing the "Methane and Petroleum Vapour Flame-Cups over the Standard Hydrogen Flame," adapted by permission from Redwood's work on Petroleum and its Products. The work begins with a preface by Professor Clowes, then follow 197 pages of subject-matter, illustrated with 48 wood engravings, a bibliographical list of works of reference, the subjects arranged alphabetically, and the alphabetical index. The subject-matter of the volume is arranged in eight chapters, with an appendix to each. These chapters treat of the following matters:—I. Conditions of Explosion of Inflammable Gases when they are mixed with Air. II. Historical Summary of Methods of Gas Testing used in the Coal Mine. III. Examination of the Accuracy and Delicacy of different Flame-Tests. IV. The Hydrogen Flame-Test for Gas. V. The Test-Chamber: A Simple Apparatus for producing and measuring Flame-Caps. VI. Detection and

Measurement of Carbonic Oxide in the Air. VII. Atmospheres which extinguish Flame and which are irrespirable. VIII. Detection and Measurement of Petroleum Vapour in the Air.

WOOL DYEING. By WALTER M. GARDNER, Head Master of the Chemistry and Dyeing Department of the Bradford Technical College. Part I. John Heywood, Deansgate and Ridgefield, Manchester; 29 and 30, Shoe Lane, London, E.C.; 22, Paradise Street, Liverpool; 33, Bridge Street, Bristol; and 15, Briggate, Leeds. 1896. Price 2s.

8vo volume, with preface, stating that the entire work will be issued in parts, of which the present forms Part I. It contains subject-matter filling 100 pages, and illustrated with 14 woodcuts. An alphabetical index concludes the work, which is subdivided into four parts or chapters, treating of the following subjects:—I. Wool Fibre. II. Wool Scouring. III. Wool Bleaching. IV. Water.

Trade Report.

TARIFF CHANGES AND CUSTOMS REGULATIONS.

(From the Board of Trade Journal.)

IMPORT DUTIES ON SOAP IN SOUTH AMERICAN COUNTRIES.

The following statement, showing the rates of import duty levied in South American countries upon soap, has been recently prepared by the Board of Trade:—

Countries.	Import Duties.
ARGENTINE REPUBLIC.	
Soap	Pays 25 per cent. <i>ad val.</i> under heading of "all goods not specially enumerated."
PARAGUAY.	
Soap	25 per cent. calculated on the value stipulated in the valuation tariff.
<i>Note.</i> —The following additional duties are leviable:—5 per cent. in gold, destined for the conversion of paper money; 4 per cent. in paper money, destined to the "Consejo S. de Educacion"; 3 per cent. in paper money, destined to the "Consejo Secundario y Superior."	
URUGUAY.	
Soap, common, of all kinds	Pesos, cts. Kilo. gross 0 68
<i>Note.</i> —Peso = 100 centesimos = 1s. (about); kilogramme = 2·2 lb.	

Countries.	Import Duties.		
	Duty.	<i>Ad Valorem</i> Rate on which Duty is based.	Tare Allowance.
BRAZIL.			
Soap, not perfumed:—	Reis.	Per Cent.	Cases, 8 per cent. Tin, gross.
Black or dark.....	Kilo. 200	48	
Yellow	" 400	48	
White	" 700	48	
" <i>Saponeas</i> ," " <i>sapolins</i> ," and similar articles.	" 1,200	48	
<i>Note.</i> —1,000 reis=1 milreis =2s. 3 <i>d.</i> (nominal value); kilogramme = 2·2 lb.			

IMPORT DUTIES ON SOAP IN SOUTH AMERICAN COUNTRIES—*cont.*

Countries.	Import Duties.
VENEZUELA.	
	Bolivars etc.
Soap, white, marbled, called Castille, Marseilles, &c.	Kilo. 1 25
Do., common	" 1 25
<i>Note.</i> —The bolivar = 9 <i>ds.</i> , and is divided into 100 centimes; kilogramme = 2·2 lb.	
COLOMBIA.	
	Pesos etc.
Common oil soap	Kilo. 0 20
Common resin and tallow soap	" 0 25
Surtax:—25 per cent.	
Reductions: 10 per cent. in the Custom-houses of Arica and Meta; 30 per cent. in the Custom-house of Tumaco; 20 per cent. in the Custom-house of Buenaventura.	
Soaps not specially mentioned	" 1 20*
<i>Note.</i> —Pesos = 100 centavos = 4s. (nominal value), actual value about 3s. 4d.; kilogramme = 2·2 lb.	
ECUADOR.	
	Sueros etc.
Soap, common	Kilo. 0 65†
<i>Note.</i> —The monetary unit employed in Ecuador is the <i>suero</i> = 100 centavos = (about) 1s.; kilogramme = 2·2 lb.	

Countries.	Value on which Duty is levied.	Rate of Import Duty.
BOLIVIA.		
	Bolivianos etc.	
Soap, common, washing, gross weight.	Kilo. 0 12	30% <i>ad val.</i>
Do., for cleaning articles of metal.	" 0 30	30% <i>ad val.</i>
Do., powdered, for washing.	" 0 35	30% <i>ad val.</i>
<i>Notes.</i> —In Bolivia the <i>ad valorem</i> duties are calculated on the official values stated above.		
The monetary unit of Bolivia is the Boliviano = 100 centavos = 4s. (nominal value), actual value 2s. 4d. (about); kilogramme = 2·2 lb.		
PERU.		
	Soles etc.	Soles etc.
Soap, common, of all kinds, and of whatever origin.	Kilo. 0 15	40% <i>ad val.</i>
Do., and soap in cakes, perfumed, common and disinfecting soaps, such as tar, carbolic, phenic, and pitch, gross weight.	" 0 40	40% <i>ad val.</i>
Do., fine (as perfumery), gross weight.	" 0 80	40% <i>ad val.</i>
<i>Notes.</i> —The <i>ad valorem</i> duties are calculated on the official values stated above.		
Sol = 101 centavos = 4s. (nominal value), real value about 2s.; kilogramme = 2·2 lb.		
CHILE.		
	Pesos, etc.	
Soap, common, for washing, Castille, Marseilles, and green soap.	Kilo, gross 0 15	25% <i>ad val.</i>
Do., for cleaning metal objects, including wrappings.	Kilo. 0 35	25% <i>ad val.</i>
Do., powdered, called "Ivory," or others similar, for washing, including wrappings.	" 0 40	25% <i>ad val.</i>
<i>Notes.</i> —The <i>ad valorem</i> duties are calculated on the official values stated above.		
Peso = 3s. 9d. (about); kilogramme = 2·2 lb.		

* According to Decree No. 453 of 1893, this duty is increased by 5 centavos, but the increased duty is not subject to the rebates in the Custom houses of Buenaventura and Tumaco, nor to the surtax of 25 per cent.

† With an addition of 30 per cent. of the duty as surtax.

‡ Including interior receptacles or packages.

RUSSIA.

Classification of Sheep-dipping Powder.

Pound = 36 lb. Avoirdupois. Gold Rouble = 3s. 2d.

Under an order of August 31, 1896, Sub. No. 17,805, Little's patent powder dip for the treatment of sheep, which consists of powdered sulphur with an admixture of arsenic, is to pay duty under point 2 of section 91 of the Customs tariff, duty 5 copecks, gold, per pound, and Little's non-poisonous fluid sheep dip under section 112, duty 1 rouble 50 copecks, gold, per pound, gross, but on condition that the delivery out of Customs-houses and the sale of the above preparations shall be effected on the general basis established for poisonous substances and against prescriptions signed by veterinary surgeons.

UNITED STATES.

Tariff Decisions.

So-called "dead," "tar," or "creosote" oil is dutiable at 25 per cent. *ad valorem* under the provision in paragraph 60, Act of August 28, 1894, for "distilled oil," and not as carbolic acid.

Quanthic ether, otherwise known as pelargonate of ethyl or pelargonic ether, is assessed for duty under paragraph 17, Act of August 28, 1894, as fruit ether, at 2 dols. per pound.

OFFICIAL REPORTS.

MINERAL STATISTICS OF THE UNITED KINGDOM FOR 1895.

Ironmonger, October 17th, 1902.

The following is the official general summary of the mineral produce of the United Kingdom and of the Isle of Man for 1895, as compared with 1894:—

Description of Mineral.	1894.		1895.	
	Quantity.	Value at the Mines and Quarries.	Quantity.	Value at the Mines and Quarries.
	Tons.	£	Tons.	£
Alum clay (Bauxite) .	7,900	5,618	10,408	2,506

WHITE LEAD TRADE AND THE MERCHANDISE MARKS ACT.

Board of Trade Journal, October 1896, 388.

The Board of Trade have received from the London Chamber of Commerce copies of circulars which have been addressed by the Chamber at the instance of the leading white lead corrodors of the United Kingdom to all the buyers and users of white lead in the country.

The circular, dated the 27th August last, states that the leading white lead corrodors have resolved to support the action taken by the Chamber in this matter as far as lies in their power, and to induce their friends to adapt the same course.

With this view, they have decided—

1. To discontinue the use of the term "best" as a trade description for admixtures of white lead, believing it to be a false and misleading description within the meaning of the Merchandise Marks Acts, 1887 and 1891;
2. To brand or stencil all packages, wooden or iron, containing white lead admixtures with the word "Reduced"; and
3. To invoice all white lead admixtures as "Reduced white lead."

The responsibility for the illegal and dishonest practice of selling reduced white lead as "Genuine" (which might be unjustly fastened upon the manufacturer in the event of his having supplied reduced white lead without brand or mark, and the packages being subsequently branded or marked by a second party "Genuine") will, it is hoped, by the means proposed be brought home to any who are guilty of the dishonest practice.

These regulations were to come into force on the 1st October last.

THE NEW RUBBER INDUSTRY IN LAGOS.

(From the "Kew Bulletin," No. 111.)

The rubber industry of Lagos (this Journal, 1896, 124) affords one of the most remarkable instances of the rapid development of an industry that has taken place in recent years in any British colony. It owes its existence to a wild plant which was only discovered in Lagos within the last two or three years. It was found to be new as a source of rubber, although there is now reason to believe it had yielded some of that formerly exported from the Gold Coast. At the present time *Kickia* rubber from Lagos has established itself as a commercial article in great demand. The exports in January 1895 were 21,131 lb., of the value of 1,214*l.* This was practically the beginning of the industry. In December 1895 the exports had increased to 948,000 lb., of the value of 51,488*l.* From a recent return communicated to Kew by the Government of Lagos, the total exports during the year 1895 amounted to 5,069,504 lb. (2,263 tons), of the value of 269,892*l.* This considerable industry has therefore been called into existence within 12 months. The rubber is

purely a forest product, and the collection and preparation of it have been effected by means of native labour. The success of the industry is another indication of the undeveloped resources of our West African colonies. It is only a few years ago that a somewhat similar, though more gradually developed, rubber industry was called into existence at the Gold Coast. The origin of this is given in the following extract from a Colonial Office Report on the Economic Agriculture of the Gold Coast in 1889:—"Although the youngest of our industries, the preparation of india-rubber is now only second in importance to that of palm oil. Attention was first drawn to this valuable product by Sir Alfred Moloney (now Governor of Lagos), when administering the Government of the Gold Coast Colony in 1882, by letters to the local press. The first practical experiments were made by Mr. F. C. Grant, of Cape Coast, whose example was quickly followed by others, and the undertaking proving remunerative, the collection of rubber began in every part of the colony. The quantity now produced annually ranges from 30,000*l.* to 40,000*l.* in value."

During the year 1893 the Gold Coast exported rubber to the extent of 3,395,990 lb., and of the value of 218,162*l.*

The following table shows the export of rubber from Lagos during 1895:—

Export of Rubber from the Colony of Lagos from 1st January to 31st December 1895.

Month.	Weight in Lb.	Value.

EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

THE ANGLO-SICILIAN SULPHUR TRUST.

U.S. Consular Reports, September 1896, 227.

The American Vice-Consul writes from Catania, August 1, 1896:—

The Anglo-Sicilian Sulphur Company, Limited, has been established in London. The capital of the company is 1,000,000*l.*, whereof 700,000*l.* are to be paid in at once. Having fulfilled all the requirements of Italian law, the company entered into operation to-day.

The completion of the trust was very uncertain until a few days ago, because the Italian Parliament refused to grant to the new company exemption from the heavy register and income taxes, which would have amounted to over 100,000*l.* Finally, however, an agreement was made by which the Anglo-Sicilian Company has to pay 1 lira per ton on all sulphur exported from Sicily.

The immediate consequence has been another sharp advance of prices—say 8 to 10 per cent.—during the last three days, and the tendency is for a further rise, especially for delivery after the 1st of October next, from which date the Italian export duty of 11 lire per ton of 1,000 kilos. has been abolished by a recent law.

The United States consume about one-third of the Sicilian production of sulphur, say 100,000 to 110,000 tons per year, and the higher prices for the crude brimstone will therefore cause great injury to the acid makers and the other manufacturers in the United States.

CHEMICAL MANURES IN BRAZIL.

Chamber of Commerce Journal, September 1896, 167.

The Belgian Consul at St. Paul reports that different manures imported from abroad have been now started with in the cultivation of coffee, and those who have used them have only had congratulations for themselves on their initiative. To come into general use their cost must be brought within the reach of the generality of planters, which has not thus far been the case. Brazilian taxes—indirect—have interfered, while most of the planters, knowing little of scientific agricultural matters, are completely ignorant of the nature and quantity of manure to use, as well as of the manner of utilising it and the period at which it is proper to spread it. This explains why they hesitate to avail themselves of it, whilst it is notorious that the soil of many plantations is already exhausted and requires artificial fertilisation. Phosphate of lime is the manure most used, and Lupton, rue S. Bento; Upton, rue Florencio de Abreu; Lion and Co.; and Camille Levy, are houses quoted by the Consul as engaged in the sale of phosphates. To manufacturers desirous of sending phosphates, the Consul thinks it useful to make the following recommendations:—(1.) State the price per 1,000 kilos., the phosphate being packed in full sacks weighing 100 kilos, each. (2.) Send with each consignment a rigorous qualitative and quantitative analysis of the substance. (3.) As far as possible give indications of the quantity it is necessary to apply to each coffee plant.

GENERAL TRADE NOTES.

THE PRODUCTION OF ALCOHOL IN ARGENTINA.

According to the Austrian *Handels Museum* for September 17, no industry has of late years made so great a progress in Argentina as that of the manufacture of alcohol. While in the year 1886 492,912 litres of alcohol were imported, the import of this article fell in 1887 to 140,135 litres, in the year 1888 to 21,038 litres, and in 1892 amounted only to 11 litres. During the last three years no alcohol whatever has been imported, as the native production is not merely sufficient for the local consumption, but supplies also more than is needed by means of the various manufacturing in which alcohol is produced, such as maize distilleries and cane-sugar factories. The existing maize distilleries are now in a position to put out about 40 million litres of alcohol, and the cane-sugar factories from 10 to 20 million litres.

It has been shown by a recent German consular report that this alcohol is employed in the manufacture of liqueurs, in the raising of the alcoholic strength of the natural wines of San Juan and Mendoza, which it had hitherto been impossible to lay down, and in the preparation of large quantities of expensive wine. In the year 1895 the consumption of wine in Argentina amounted to some 24 million litres, of which scarcely 6 millions remained in their natural condition.

In order to deal with the serious over-production and the consequent reduction in value of alcohol, the owners of almost all the maize distilleries formed a syndicate in the year 1894, and pledged themselves to limit the production of alcohol and to accommodate themselves to the condition of the market. But, in spite of this, during the second half of that year the prices of alcohol continued to go down, as the cane-sugar factories in Tucuman flooded the market with huge quantities of alcohol prepared from cane-sugar and from molasses to such an extent that when the article came on the market it often did not fetch the bare cost of original production. This over-stocking of the market with Tucuman alcohol takes place with regularity after the close of the sugar manufacturing in the months from July to January, as the working up of the waste molasses cannot be undertaken until the price of alcohol becomes higher, and the smallest sugar factories have enough capital in hand to lay in alcohol for a considerable time.

With regard to the fact that the sugar factories buy no raw material for the production of alcohol, but make it themselves out of the material they possess, the only possible chance of a diminution of the product of alcohol is a

lessening of the expense of extracting sugar. The syndicate mentioned above already in the year 1895 monopolised the entire alcohol business of the country by buying up the total amount of alcohol manufactured in the sugar factories at a relatively low price. By doing this, the syndicate prevented the tender during the months just mentioned from being excessive, and continued, by means of their own restricted production, to obtain fair prices.

PRODUCTION OF QUICKSILVER IN CALIFORNIA.

The *Engineering and Mining Journal* (New York) states that quicksilver production in California has shown this year a considerable increase, the total receipts at San Francisco for the six months ending with June having been 18,439 flasks, a gain of 4,743 flasks, or 34·6 per cent., over the first half of 1895, and of 6,033 flasks, or 18·7 per cent., over 1894. While these receipts gauge the rate of production very fairly, they do not give the whole amount, as the reports do not include the quicksilver sold directly from the mines, nor that shipped from them to the East by rail, which does not come to San Francisco at all.

The larger output seems to have been absorbed without difficulty. In addition to the greater demand from the California mines, there has been a growth in exports very nearly corresponding to that in the production. The trade with China, which had been suspended for several years, has been renewed, and has aided materially in disposing of the increased production.

TIN PLATES IN THE UNITED STATES.

Engineering and Mining Journal, Sept. 26th, 1896, 289.

The growth of the tin-plate industry in the United States is illustrated by the fact that the imports of tin from the Straits direct for the seven months ending with July this year reached a total of 9,048 long tons, or more than twice the quantity noted for the corresponding period last year. This year the United States took 29·7 per cent. of the total shipments from the Straits, against 15·1 per cent. last year. This statement includes only the direct shipments, and makes no mention of the metal which goes by way of England and Holland.

While the total tin imports into the United States for the earlier months of this year showed a gain, the business depression affected them later in the year, and the total for the seven months elapsed has been 10,586 long tons, against 14,416 tons last year. Nearly all this decrease was in the months of June and July. The imports of tin plates decreased from 294,848,812 lb. in the seven months of 1895, to 179,386,938 lb. this year, showing a decrease of 39·2 per cent.

QUARTZ SLATE.

Engineering and Mining Journal, Sept. 19th, 1896, 274.

Quartz slate, a highly refractory natural stone, is quarried at Crummendorf, near Strehlen, Silesia. It is, according to a recent German report, a cheap substitute for the best fire-brick. Quartz slate is a mineral of grayish-white colour, and is of rare occurrence, the Crummendorf quarry being the only one in Germany. Examined by means of a microscope, it shows a fine texture of sharp quartz molecules, which can only have by the pressure of an enormously high water column been brought into connection. The slate is found in layers from 2 in. to 10 in. in thickness. Its high contents of silica (91·4 per cent.) make it extraordinarily fireproof, and it can be worked easily on account of its softness. Quartz slate will, it is stated, last three times as long as the best fire-brick, even if subjected to the highest temperatures. Since 1854 it has been extensively used in Eastern Germany, especially in the manufacturing district of Upper Silesia, in Austria-Hungary, and in Russia, and has recently been used in the Rhine province and Westphalia for cupola, welding, and puddling furnaces, Bessemer converters, &c.

PETROLEUM IN CANADA.

Ironmonger, October 3rd, 1896, 3.

The United States predominate so greatly in the American production of petroleum that the Canadian output of that

oil is rather apt to be overlooked. Statistics show, however, that a very considerable quantity of petroleum is raised in British North America, chiefly in the province of Ontario, with the town of Petrolia as the centre of the oil-producing district. In the year 1886 the total quantity of petroleum raised in Canada was 486,441 barrels (of 35 Imperial galls. each, equal to the American barrel of 42 Winchester galls.), of which the value was 437,797 dols. In 1887 the production was 763,933 barrels, or nearly double the quantity of the previous year, but since then the output has not been greatly augmented, and has been fairly steady year by year. In 1895 it was 802,574 barrels (or about 27,000 barrels less than in 1894), the value being 1,201,186 dols., which was the highest total recorded for any one year in the history of the industry. The lowest average price was 78 cents in 1887, and the highest 1 dol. 49³ cents in 1895. The following table gives in comparative form and in detail the Canadian production in 1894 and 1895:—

Product.		1894.	
		Quantity.	Value.
			Dols.
Illuminating oils	Imp. Galls.	11,289,741	1,003,973
Benzine and naphtha	" "	645,031	51,515
Paraffin oils	" "	1,282,749	118,053
Gas and fuel oils	" "	7,323,374	197,193
Lubricating oils and tar	" "	1,801,174	74,309
Paraffin wax	Lb.	1,350,172	119,091
Total			1,567,134

Product.		1895.	
		Quantity.	Value.
			Dols.
Illuminating oils	Imp. Galls.	10,921,826	1,237,328
Benzine and naphtha	" "	7,081,717	285,308
Paraffin oils	" "	1,364,228	86,608
Gas and fuel oils	" "	2,213,639	79,589
Lubricating oils and tar	" "	2,400,404	205,591
Paraffin wax	Lb.	1,261,228	85,608
Total			1,981,632

There is an oil exchange at Petrolia, but its operations are decreasing yearly, owing to the oil being sold direct to the refiners by the producers.

ACETYLENE FOR LIGHTING.

Chemist and Druggist, October 17th, 1896, 580.

A committee, consisting of MM. Troost and Schutzenberger, of the Academy of Sciences, Professors Moissan and Riche, of the Paris School of Pharmacy, MM. Michel Lévy, Bunel, and Vieille, with seven assistant commissioners appointed by the Hygienic Council of the Seine Department to study the preparation of acetylene for lighting purposes, have lately published the report. It appears, with a postscript, in the form of a series of regulations issued by the Prefect of Police, to whom notice must be given by anyone desiring to employ the new gas on his premises. It must not be used in cellars or close courts, the apparatus must be in a light, airy place, and the reserve stock kept out of the sun. The liquids and refuse are to be diluted with water (1 to 10) before being emptied into drains. Receivers of less than 10 kilos. pressure to be tested by proprietor, and fitted with manometer; those with pressure above 15 kilos. to be tested by a Government engineer (School of Mines). Wrought-iron receivers to be used, and tested every three years by the above-named official, who will stamp them with certain details as a proof of examination.

PRODUCTION OF CHLORATE OF POTASH AT NIAGARA FALLS.

Mr. O. E. Dunlap describes, in a recent issue of the *Electrician*, the works of the Chemical Construction Company at Niagara Falls, which are now, he states, in operation.

The company have leased 8 acres of land, which includes permission to use 4,000 h.p. of electricity; but at present they have built but three workshops on a small portion of the land, and are using 500 h.p. They are making chlorates by the Blumberg process, and propose to make chloroform and iodoform later on.

In making chlorate of potash the process is started by dissolving the chloride in five tanks of 3,000 galls. capacity. From these tanks the solution is pumped by steam to the upper floor of the main building, where it passes through filters, and then into a storage tank of 4,000 galls. capacity. From this tank the solution is tapped off for use in the pot-room on the same floor. The main switchboard controlling the flow of the electric current is on the east side of the building and above the transformer room. In addition to this main switch, each pot has a switch by which it can be thrown in or out of circuit. There are 60 pots, 8 ft. long and 4 ft. or 5 ft. wide, made of iron and lined with porcelain. The pots are all insulated one from the other, and also from the floor. In these pots the chloride solution is decomposed, forming the chlorate, which is allowed to run down to the first floor into porcelain-lined crystallising tanks or pans, then into lead-lined pans, and finally into wooden pans, shown in the above illustration, after which it is shovelled up and thrown into a centrifugal dryer. It is next placed in the dry room, where the remaining moisture is removed, after which it goes into the packing room, where it is put up in 100-lb. kegs and sealed for shipment. From the time the chloride solution enters the pot-room to the time the chlorate is ready for shipment about 24 hours elapse. The present capacity of the plant is about 1 ton of chlorate of potash per day.

Mr. Dunlap describes the electrical equipment, and adds that chlorate of potash is now made by three electrical processes—namely, those employed by Gall and Monthauer, of France; by Franehot and Gibbs, of Buckingham (Canada); and Blumberg's process employed by the Chemical Construction Company.

CALIFORNIAN OLIVE OIL.

Chemist and Druggist, October 17th, 1896, 580.

Californian olives will bring the State 2,000,000 dols. this year, or eight times as much as last year's crops. Part of the olives only is used for making oil, and at present it is wholly consumed locally. The largest olive mill in the country is in Pomona, says Mr. E. J. Eastman in the *Pharmaceutical Era*. The power is a six horse-power engine. The grinders consist of two great rollers of 900 lb. each, revolving in a hollow pan-like iron receptacle 6 ft. in diameter and 1 ft. deep. The olives are run into this receptacle to the depth of several inches. The rollers are started, and the olives are ground into a pomace, like Hamburg steak. The pomace is then packed in "bruseoles," and placed in a 100-ton hydraulic press. The pressure, which must be gradual and slow, is put on, and then stopped till the oil has been allowed to drip out; then a little more pressure is used, and this is repeated until the oil has been pressed out. As it comes from the press it looks like black oil, or crude petroleum, but soon separates, with the oil on top. It is then put into large tanks, and allowed to stand for several weeks, to clarify. Then it is filtered through sand and charecoal, and lastly through white filter paper.

DENATURING OF ALCOHOL IN FRANCE IN 1885—1894.

Zeits. für Spiritusind. 1896, 19, 289.

The following figures represent the quantities of alcohol which were denatured in France in the years 1885 to 1894:—

	Hectol.		Hectol.
1885	49,285	1890	109,842
1886	59,196	1891	105,742
1887	85,400	1892	104,347
1888	107,063	1893	106,939
1889	108,210	1894	120,798

The quantities of denatured spirit used for various purposes during 1890—1894 are given as follows:—

	1890.	1891.	1892.	1893.	1894.
	Hl.	Hl.	Hl.	Hl.	Hl.
For heating purposes ..	37,316	45,705	52,500	53,702	65,826
For lighting purposes ..	4,111	6,068	1,513	4,990	1,398
For manufacture of varnish.	12,450	11,781	10,876	11,740	11,295
For manufacture of hats and in dyeing.	392	210	377	617	2,219
For manufacture of ether.	30,901	27,926	25,554	22,178	31,877
For manufacture of aldehyde.	3	9	18	45	..
For manufacture of fulminates, alkaloids, &c.	3,350	2,547	1,816	2,557	2,654
For destruction of insects.	9	2	8	5	18
For other purposes.....	15,187	11,534	9,296	11,105	2,601

—A. K. M.

MANUFACTURE OF STARCH AND STARCH PRODUCTS IN FRANCE.

D. Saure. Zeits. für Spiritusind. 1896, **19**, 295—296.

There are about 550—600 works in France in which starch and starch products are manufactured. Of these, 450—500 are potato-starch works, in the largest of which, in Châlons-sur-Saône, 200,000 kilos. of potatoes can be treated in a day. There are also about seven works in which maize starch and four or five in which wheat starch is manufactured. In addition to these there are 19 glucose, 20 caramel, and four dextrin works.

The amount of starch manufactured is difficult to estimate, but is probably about 1,500,000 to 2,000,000 cwt. The production and export of glucose, compared with that of Germany, is as follows:—

	Production in	
	France.	Germany.
	Cwt.	Cwt.
1893-94	332,000	380,000
1894-95	531,000	350,000

	Export from	
	France.	Germany.
	Cwt.	Cwt.
1893-94	12,000	57,700
1894-95	22,700	15,000

The import duty in France on 100 kilos. of the different products is as follows:—

	Francs.
Grain starch (amidon)	15
Potato starch (féoule)	12
Glucose	70
Maize	3

—A. K. M.

MINERAL OIL AND PARAFFIN INDUSTRIES.

Krey. Chem. Rev. Fett u. Harz Ind. **3**, 174, 186, 198.

In considering the possibility of a petroleum monopoly by the Russian and American producers, the author points out that the development of the Galician oil-fields and the low price of gas are factors militating against the success of such a scheme.

Turning to the proposed differential tariff on crude oil to favour the establishment of an oil-refining industry in Germany, he refers to the practice, latterly developed in Austria, of defrauding the revenue by declaring as crude oil refined oil mixed with 10 per cent. of heavy oil, whereby it acquires the appearance of the unrefined article; and expresses the opinion that whilst the proposed change

would benefit German industries but little, it would practically kill the brown coal-tar oil and paraffin industry in Saxony and Thuringia, since the centres of this industry are not favourably situated for the reception of imported oil, being remote from the great waterways; neither is the plant adapted for the refining of petroleum. These circumstances, coupled with the insecurity attaching to an industry wholly depending on foreign countries for its raw material, render the projected change undesirable from an economic point of view.—C. S.

THE RUSSIAN DRUG TRADE.

Chemist and Druggist, October 24th, 1909.

In view of the possible abolition of, or considerable reduction in, Customs duties on drugs and chemicals imported into Russia, the following table, taken from the official Russian Customs statistics, will be of interest as showing the imports of the principal drugs and chemicals into that country during 1894 and 1895:—

	Quantities in Thousands of Pounds.		Value in Thousands of Roubles.	
	Pound = 36 lb. Av.		Gold R. = 3s. 2d.	
	1894.	1895.	1894.	1895.
Benzoic acid and camphor.	44	38	422	308
Gums and gum-resins, unenumerated.	351	341	7,739	7,770
Chemicals and druggists' goods.	5,740.3	5,433.3	13,042	12,450
Including sulphur ..	1,313	1,192	960	582
" borax	54	66	70	47
" sal ammoniac and ammonia.	63	94	226	282
Chlorides of magnesium and sodium, and Epsom salts.	204	236	186	195
Bleaching powder	444	399	908	794
Caustic soda and potash	436	394	1,051	980
Bicarbonate of soda and potash.	81	80	230	227
Other salts of soda and potash.	305	333	457	512
Sulphuric acid	39	18	67	28
Nitric and hydrochloric acids.	197	83	459	354
Stassfurt salts	317	273	141	165
Nitrate of soda	860	752	894	624
Glauber salts	223	196	248	200
Fatty vegetable oils	751	722	5,773	5,648
Cocoa and palm oils	200	192	942	802
Essential oils	4.1	4.0	454	459
Cosmetics	11.3	13.2	792	831
Dyes and colours	4,087.8	3,907.1	14,788	16,133
Vegetable pigments	2,777	2,551	2,697	2,545
Colouring earths	349	374	534	537

OUTPUT OF CHEMICALS IN GERMANY.

Chemist and Druggist, October 24th, 1909.

According to official statistics, the following quantities of minerals and metals were produced in Germany last year:—Bismuth, 1,000 kilos., value 7,000 m.; cadmium, 7,047 kilos., value 39,238 m.; antimony, 924 tons, value 29,4612 m.; arsenic and arsenical compounds, 1,788 tons, value 393,451 m.; sulphur, 1,819 tons, value 136,340 m.; sulphuric acid, 416,239 tons, value 11,579,483 m.; hydrochloric acid, 8,627 tons, value 120,741 m.; nitric acid, 1,922 tons, value 555,619 m.; muriatic acid, 2,641 tons, value 157,062 m.; colouring earths, 2,059 tons, value 155,451 m.

IODINE MANUFACTURE IN JAPAN.

Chemist and Druggist, October 24th, 1909.

It is well known that enormous quantities of seaweed containing iodine are gathered along the coasts of Japan, and were it not for the fact that the manufacture of iodine from kelp is scarcely profitable in view of the competition of the Chilean product, Japan would no doubt be one of the principal iodine-producing countries. In fact, even under

the present circumstances, Japanese iodine and iodides find a market locally, and have even been seen in Europe in commercial quantities. A proposal has now been made to the Japanese Government by certain native chemists that the Customs duty on iodine and iodides in Japan should be increased to such an extent as to enable the Japanese industry to be self-supporting.

A FATAL ACETYLENE EXPLOSION.

Chemical Trade Journal, October 24th, 1896, 256.

A terrible explosion occurred on October 17th, at the works of M. Raoul Pietet, 136, Rue Championnet, Montmartre, Paris, through the explosion of a vessel containing acetylene gas. The accident took place in the gasometer room, which is a special building over 30 feet high, situated at the back of the main portion of the factory, and separated from it by a small courtyard. Only two men were in the room at the time, and they were both killed on the spot. They were engaged in checking a number of recently returned cylinders of liquefied acetylene gas. It is uncertain how the explosion occurred, but at present it is attributed to a leakage igniting at the open flame of a lamp. The walls of the building were blown down, and the neighbouring buildings were damaged. Near the gasometer room there is a small boiler-house, and the stoker engaged there was slightly wounded by splinters of glass. In all the other buildings of the factory, the engine-house, and the storehouses not a pane of glass was left unbroken. The courtyards of the adjoining premises are also all strewn with broken glass and with pieces of masonry belonging to the wrecked gasometer-house. It is astonishing that the gasometer itself, which is quite close, did not also blow up. Had it done so the explosion would have devastated the whole quarter.

DOMESTIC GAS FROM BY-PRODUCT OVENS.

Engineering and Mining Journal, October 17th, 361.

The first of the series of by-product coke-oven plants which it is proposed to build on the seaboard will shortly be in operation at Halifax, Nova Scotia. The ovens are of the Otto-Hoffmann type, and the company has arranged to furnish both fuel and illuminating gas to the city of Halifax, in addition to manufacturing coke and saving the ammonia sulphate and other by-products. At this plant of course, Cape Breton coal will be used. It is announced also that plans are being prepared for the larger plant which the same parties, under the organisation of the Massachusetts Pipe Line Company, purpose building near Boston; but work will not be begun until some experience is had at Halifax. At Boston it is the intention to use also Cape Breton coal, from the Dominion Coal Company's mines.

The people who are managing this enterprise are also interested in the United Coke and Gas Company, which is building a large plant of Otto-Hoffmann coke ovens near Pittsburg. The projectors are confident that they will be able, in the Eastern plants, to find a good market for their coke, and to reduce largely the cost of supplying gas; especially fuel gas, which they expect to furnish on a large scale to the cities.

BY-PRODUCTS IN COKE MANUFACTURE.

Engineering and Mining Journal, October 17th, 1896, 369.

A calculation was recently made by Herr E. Hagenstock, of Dahlhausen, which should be of interest to coke-makers. He told the members of a German technical society that in the Rhenish-Westphalian district alone about 6,000,000 tons of coke are now produced and consumed, for which 8,000,000 tons of coking-coal are required. If only 1 per cent. of ammonia sulphate be regarded as recoverable on an average, it will be seen that a quantity of 80,000 tons of this substance can thus be recovered yearly; and, at the low price of 1 mark per kilo. of nitrogen, amounting, with a 20 per cent. nitrogen content in the ammonia sulphate, to 200 marks per ton of this salt, the total saving would be 16,000,000 marks.

SAUERBECK'S TABLES.

Textile Recorder, October 15th, 1896.

(See this Journal, 1894, to face 762; 1895, 609.)

Mr. Sauerbeck's index numbers for August and September show a considerable rise in the prices of commodities since the end of July, when the lowest level ever recorded was reached. The recovery during the two months was from 59.2 to 61.3, the rise being 2.1, or at the rate of 3.54 per cent. The index number still stands, however, below that of the whole of 1895, which was itself under the figure for any previous year. In the following table the average numbers for each twelvemonth since 1890, as well as the course of the decline this year to July and the subsequent upward movement, are indicated:—

Index Numbers of Commodities.

Year 1891	72	December, 1895	61.2
Year 1892	68	March, 1896	60.7
Year 1893	68	April, 1896	60.3
Year 1894	63	May, 1896	60.1
Year 1895	62	June, 1896	59.3
		July, 1896	59.2
		August, 1896	59.7
		September, 1896	61.3

BOARD OF TRADE RETURNS.

SUMMARY OF IMPORTS.

Articles.	Month ending 30th September.	
	1895.	1896.
	£	£
Metals	1,444,864	1,614,578
Chemicals and dyestuffs	119,963	450,451
Oils	596,581	676,216
Raw materials for non-textile industries	1,319,668	4,541,461
Total value of all imports	30,618,554	33,111,156

SUMMARY OF EXPORTS.

Articles.	Month ending 30th September.	
	1895.	1896.
	£	£
Metals (other than machinery)	2,480,097	2,780,378
Chemicals and medicines	649,704	639,278
Miscellaneous articles	2,696,148	2,679,516
Total value of all exports	19,461,940	19,797,980

IMPORTS OF METALS FOR MONTH ENDING 30TH SEPTEMBER.

Articles.	Quantities.		Values.	
	1895.	1896.	1895.	1896.
Copper:—			£	£
Ore	8,958	10,704	57,099	44,422
Regulus	6,192	5,685	120,508	154,242
Unwrought	2,806	5,246	126,869	255,684
Iron:—				
Ore	441,292	419,855	288,836	296,206
Bolt, bar, &c.	7,105	7,307	58,545	59,582
Steel, unwrought ..	707	1,446	5,882	17,731
Lead, pig and sheet ..	8,792	12,073	92,720	136,090
Pyrites	34,694	56,504	63,866	103,453
Quicksilver	71,640	64,200	6,920	5,680
Silver ore	Value £	..	119,980	97,162
Tin	73,495	67,317	237,903	202,932
Zinc	5,383	5,227	85,078	87,830
Other articles	Value £	..	173,718	152,964
Total value of metals	1,444,864	1,614,578

IMPORTS OF CHEMICALS AND DYE-STUFFS FOR MONTH
ENDING 30TH SEPTEMBER.

Articles.	Quantities.		Values.	
	1895.	1896.	1895.	1896.
Alkali..... Cwt.	11,616	10,238	£ 8,664	£ 7,949
Bark (tanners', &c.) ..	37,216	25,572	12,759	8,149
Brimstone.....	21,761	42,804	5,693	11,068
Chemicals..... Value £	101,588	127,162
Cochineal..... Cwt.	306	686	1,967	4,641
Cutch and gambier Tons	1,732	1,894	38,828	32,960
Dyes:—				
Alizarin..... Value £	20,081	19,393
Anilin and other	27,604	40,046
Indigo..... Cwt.	1,451	830	15,611	11,049
Nitrate of potash ..	17,136	24,671	15,790	20,047
Valonia..... Tons	1,780	2,805	20,918	33,013
Other articles... Value £	150,550	135,013
Total value of chemicals	£19,963	450,451

IMPORTS OF OILS FOR MONTH ENDING 30TH SEPTEMBER.

Articles.	Quantities.		Values.	
	1895.	1896.	1895.	1896.
Cocoa-nut..... Cwt.	25,056	14,398	£ 27,671	£ 15,694
Olive..... Tuns	733	961	27,497	31,190
Palm..... Cwt.	90,495	89,644	95,023	91,814
Petroleum..... Gall.	14,664,690	15,393,970	273,821	276,296
Seed..... Tons	1,919	2,655	38,396	55,433
Train, &c..... Tuns	2,268	2,370	35,739	38,431
Turpentine..... Cwt.	27,894	72,187	28,284	68,269
Other articles... Value £	70,240	99,080
Total value of oils...	506,581	676,216

IMPORTS OF RAW MATERIALS FOR NON-TEXTILE
INDUSTRIES FOR MONTH ENDING 30TH SEPTEMBER.

Articles.	Quantities.		Values.	
	1895.	1896.	1895.	1896.
Bark, Peruvian .. Cwt.	1,263	2,724	£ 2,128	£ 3,800
Bristles..... Lb.	462,595	437,628	60,190	62,097
Caoutchouc..... Cwt.	24,757	32,559	219,201	403,169
Gum:—				
Arabic.....	4,060	2,379	9,581	4,574
Lac, &c.....	4,425	3,176	24,896	15,531
Gutta-percha.....	3,999	3,204	26,930	32,030
Hides, raw:—				
Dry.....	20,152	23,006	70,212	38,539
Wet.....	51,611	53,046	125,043	119,775
Ivory.....	619	1,039	27,156	42,071
Manure:—				
Guano..... Tons	7,160	4,393	53,484	12,450
Bones.....	4,289	2,331	18,131	6,068
Nitrate of soda....	6,357	1,093	51,305	8,475
Phosphate of lime ..	17,854	25,081	28,680	36,030
Paraffin..... Cwt.	54,181	78,400	58,395	73,401
Linen rags..... Tons	2,129	1,092	17,206	12,352
Esparto.....	22,742	12,120	59,883	50,239
Pulp of wood.....	29,000	28,912	159,102	145,296
Rosin..... Cwt.	106,763	108,512	27,996	27,046
Tallow and stearin ..	104,560	97,281	123,670	94,790
Tar..... Barrels	36,159	29,548	29,074	17,428
Wood:—				
Hewn..... Loads	275,862	258,891	535,984	518,117
Sawn.....	743,567	822,220	1,539,537	1,896,946
Staves.....	21,503	14,050	67,274	56,005
Mahogany..... Tons	3,054	7,324	23,353	62,982
Other articles..... Value £	931,302	830,379
Total value	4,319,968	4,541,461

Besides the above, drugs to the value of 79,413*l.* were imported, as against 192,719*l.* in September 1895.

EXPORTS OF METALS (OTHER THAN MACHINERY) FOR
MONTH ENDING 30TH SEPTEMBER.

Articles.	Quantities.		Values.	
	1895.	1896.	1895.	1896.
Brass..... Cwt.	8,548	3,280	£ 34,402	£ 40,992
Copper:—				
Unwrought....	60,106	33,619	144,761	81,919
Wrought.....	25,196	18,978	70,103	58,612
Mixed metal....	24,371	16,209	52,325	39,780
Hardware..... Value £	164,690	175,771
Implement.....	101,462	118,192
Iron and steel... Tons	269,346	314,736	1,709,377	1,978,784
Lead.....	2,739	3,730	33,152	45,851
Plated wares... Value £	32,420	39,055
Telegraph wires	45,268	76,273
Tin..... Cwt.	7,833	12,048	26,799	38,296
Zinc.....	12,204	15,574	8,450	11,925
Other articles... Value £	53,918	74,921
Total value	2,480,097	2,780,378

EXPORTS OF DRUGS AND CHEMICALS FOR MONTH
ENDING 30TH SEPTEMBER.

Articles.	Quantities.		Values.	
	1895.	1896.	1895.	1896.
Alkali..... Cwt.	519,068	381,326	£ 126,360	£ 100,554
Bleaching materials ..	104,723	90,042	39,161	29,992
Chemical manures.....	30,694	39,556	156,125	159,804
Medicines..... Value £	88,827	95,338
Other articles.....	238,693	253,590
Total value	649,706	639,278

EXPORTS OF MISCELLANEOUS ARTICLES FOR MONTH
ENDING 30TH SEPTEMBER.

Articles.	Quantities.		Values.	
	1895.	1896.	1895.	1896.
Gimpowder..... Lb.	662,700	551,800	£ 13,704	£ 9,823
Military stores... Value £	190,106	71,240
Candles..... Lb.	1,657,200	1,746,000	27,756	26,067
Caoutchouc..... Value £	97,519	99,569
Cement..... Tons	37,027	34,898	61,060	55,376
Products of coal Value £	104,126	118,971
Earthenware	146,901	137,646
Stoneware.....	13,076	17,238
Glass:—				
Plate..... Sq. Ft.	129,273	109,823	7,986	7,148
Flint..... Cwt.	7,832	9,421	17,945	19,400
Bottles.....	63,381	69,246	30,656	33,971
Other kinds....	19,372	20,351	13,977	15,515
Leather:—				
Unwrought	13,213	12,304	127,155	109,709
Wrought..... Value £	38,131	44,751
Seed oil..... Tons	3,267	5,186	67,813	93,399
Floorecloth..... Sq. Yds.	1,645,500	1,745,700	6,673	74,508
Painters' materials Val. £	123,066	130,924
Paper..... Cwt.	73,771	87,779	119,728	137,227
Rags..... Tons	3,871	4,683	21,729	27,063
Soap..... Cwt.	60,160	46,976	62,667	52,362
Total value	2,696,148	2,670,516

Monthly Patent List.

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

- 20,431. L. F. Haubtman. Improvements in apparatus for clarifying saccharine solutions. Sept. 15.
 20,716. A. Müller, jun. An improved drying kiln with sinking shelves. Complete Specification. Sept. 18.
 20,982. J. Van Ruymbeke and W. F. Jobbins. Improvements in distilling apparatus. Complete Specification. Sept. 22.
 21,203. J. H. W. Ortmann and C. W. C. Herbst. New or improved apparatus for pasteurising liquids. Complete Specification. Sept. 24.
 21,579. G. A. Oncken. Improvements in injectors suitable for use with liquid fuel. Sept. 29.
 21,597. J. H. R. Dinsmore. Improvements in and connected with thermometers. Sept. 30.
 21,696. J. H. Dunn and J. A. S. Colquhoun. Improved means for drying or superheating steam. Sept. 30.
 22,060. W. F. E. Casse. Improvements in apparatus for heating, pasteurising, and cooling liquids. Complete Specification. Oct. 5.
 22,109. W. B. Strype and J. A. Mason. Improvements in metal hampers or baskets for earboys. Oct. 6.
 22,385. F. A. Roche. An improvement in the construction of filter presses. Oct. 9.
 22,675. J. B. Fenby. Improvements in manufacturing porous carbon blocks for use in filters. Oct. 13.
 22,777. T. Levoz. Improvements in converters. Oct. 14.
 22,811. F. N. Cookson and J. Stewart. Improved means for providing for the collection and removal of saline and other deposits from steam boilers, evaporators, and the like. Oct. 14.

COMPLETE SPECIFICATIONS ACCEPTED.*

1895.

- 19,356. E. Thomas. Continuous kilns.
 19,623. A. Thomson. Apparatus for evaporating and condensing. Sept. 30.
 19,754. H. W. Godfrey. Masticators or mixers suitable for the preparation of linoleum and other plastic materials. Oct. 21.
 20,998. W. H. Stead. Apparatus for forming into cakes pulverulent, granular, or pasty coherent material, such, for instance, as oil-seed meal. Oct. 7.
 21,468. W. Calver. Apparatus for the manufacture of gases. Oct. 7.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

- 20,258. O. Hehner and R. M. Prideaux. Improvements in incandescent mantles. Sept. 14.
 20,294. E. Le Riche. Improvements in incandescent gas lamps or burners, and in the mode of constructing the same. Sept. 14.
 20,406. R. Trost. Improvements in acetylene gas lamps. Sept. 15.
 20,490. A. Barham. An improvement or improvements in or connected with candles. Sept. 16.
 20,501. H. Hill. Improvements in the manufacture of thread foundations or caps for incandescent mantles. Sept. 16.

20,529. G. S. T. Gastine. Improvements in and in apparatus for the production of acetylene. Complete Specification. Sept. 16.

20,599. J. A. Denthier. Improvements in and relating to method of and apparatus for producing acetylene gas. Complete Specification. Sept. 17.

20,602. W. B. Rickman.—From J. Pintsh. Apparatus for the production of acetylene gas. Complete Specification. Sept. 17.

20,608. R. Türr. Improvements in lamps for generating and burning acetylene gas. Sept. 17.

20,694. W. P. Thompson.—From V. I. Comucci. Improvements in apparatus for generating and storing acetylene gas. Sept. 18.

20,713. J. L. Waldapfel. Improvements in or relating to burning liquid hydrocarbons in conjunction with an incandescent hood or mantle to produce an incandescent oil burner. Complete Specification. Sept. 18.

20,895. D. D. Esson. An improved combustible compound or fuel. Sept. 21.

20,903. V. Sardi. Improvements in apparatus for the manufacture of acetylene gas. Complete Specification. Sept. 21.

21,098. S. Katz. Improvements in the manufacture of charcoal fuel blocks. Complete Specification. Sept. 23.

21,267. G. Löwenberg. Composition to be used in the manufacture of glow bodies for incandescent lamps. Complete Specification. Sept. 25.

21,351. A. Kay. Improvements in and relating to apparatus for the generation and storage of acetylene gas. Sept. 26.

21,374. J. D. Palmer, H. Palmer, and H. E. Trestrail. Improvements in night lights. Sept. 26.

21,468. S. Kon. Improvements in generators for acetylene gas. Complete Specification. Sept. 28.

21,667. A. Köhler. Improvements in apparatus and materials for carburetting air. Complete Specification. Sept. 30.

21,682. H. Palmer. Improvements in the treatment of paraffin scale or paraffin. Sept. 30.

21,695. J. B. Fournier. Improvements in apparatus for containing and supplying liquefied gas for lighting and other purposes. Sept. 30.

21,698. A. H. Barker. Improvements in and relating to generators for acetylene gas. Sept. 30.

21,758. E. C. L. Pillion and C. Bertolus. Improvements in apparatus for generating and storing acetylene gas. Oct. 1. Date applied for April 1, 1896, being date of application in France.

21,769. H. Maximi. Improvements in and relating to the manufacture of incandescence bodies for illuminating purposes. Oct. 1.

21,947. H. L. A. Luchaire. Improvements in apparatus for the manufacture of acetylene gas. Filed Oct. 3. Date applied for March 3, 1896, being date of application in France.

22,068. H. L. A. Luchaire. Improvements in apparatus for the manufacture of acetylene gas. Filed Oct. 5. Date applied for April 30, 1896, being date of application in France.

22,185. C. Morris. Improvements in or connected with burners for incandescent gas lighting. Oct. 6.

22,194. P. Jebsen. A process for carbonisation of peat by electric heating. Complete Specification. Filed Oct. 6. Date applied for March 13, 1896, being date of application in Norway.

22,347. H. Winkler. Improvements in incandescent gas light are lamps. Oct. 8.

22,359. E. H. Maddock and W. Jones. Improvements in acetylene gas generators and gasometers. Oct. 8.

22,457. H. D. Fitzpatrick.—From The Actien Gesellschaft für Fabrikation von Broncewaaren und Zinkguss vormals J. C. Spinn und Sohn. Improvements in the burners of incandescent gas lights. Oct. 10.

22,480. R. J. Uppihart and G. Kros. Improvements in and connected with the production of illuminating and heating gas. Oct. 10.

22,526. L. T. FitzGibbon. Improvements in and connected with the production of acetylene gas. Oct. 10.

22,549. J. H. Darby. Improvements in the manufacture of gas with recovery of by-products. Oct. 10.

22,570. H. Akeroyd. A new and improved mantle or veil for incandescent gas lights. Oct. 12.

22,628. E. A. Morton-Brown and F. Maundrell. Improved apparatus for the production and storage of acetylene gas. Oct. 12.

22,646. A. G. Smith. Improved acetylene gas generator, purifier, and holder. Oct. 13.

22,647. A. J. Smith and A. G. Smith. A method of adapting acetylene gas for use on cycles, carriages, or other vehicles. Oct. 13.

22,741. A. J. Boulton.—From G. Zambaldi. Improvements in or relating to the production and treatment of acetylene gas, and in apparatus connected therewith. Oct. 13.

22,782. P. Sylva. An apparatus for producing acetylene. Oct. 14.

22,787. A. Schemidt and O. Kaufman. Improvements in the production of acetylene gas and in apparatus therefor. Oct. 14.

22,812. E. Martin and A. Tournier. An improved burner for incandescent gas light. Oct. 14.

22,828. C. W. S. Crawley, A. Soames, and C. V. Drysdale. A method of obtaining a continuous supply of gas or vapour under pressure. Oct. 14.

22,887. G. E. Stevenson. Certain improvements in the construction of gas-retort settings and regenerator furnaces for the same. Oct. 15.

22,956. J. B. Heal and S. H. Heal. Improvements in system connected with the installation of acetylene gas and fittings. Oct. 16.

23,006. A. Quentin. Improvements in and relating to incandescent bodies for heating purposes. Oct. 16.

23,080. B. H. Thwaite. Improved methods of utilising fuel for evaporating brine, aqueous and other solutions. Oct. 17.

23,079. O. Streiber and F. Kiefer. Improvements in factory fuel. Complete Specification. Oct. 17.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

13,510. J. Green. An improved method or process for use in obtaining hydrogen gas from water, and means for obtaining, by the aid of such method or process, carburetted hydrogen and other combinations of hydrogen, and apparatus for use in such method or process. Sept. 23.

16,431. J. Chagot. Apparatus for compressing coal-dust and the like mixture into fuel cakes. Oct. 14.

18,156. G. Haycraft. Manufacture of fuel. Sept. 30.

18,263. W. H. Wheatley.—From C. Schmid. Manufacture of incandescence bodies for illuminating purposes. Sept. 30.

18,395. J. T. Thomas and A. V. Hunt. Manufacture of coal-gas. Sept. 30.

19,243. C. Weygang. Manufacture of artificial fuel. Oct. 14.

19,830. A. Davis. Apparatus for the production or generation of gas for artificial lighting and motive-power purposes. Oct. 21.

21,545. G. C. Fowler and M. B. Fowler. Improvements in night lights, and in cases and holders for the same, and an apparatus employed in the manufacture of the said night lights. Oct. 7.

23,521. G. Trouvé. Apparatus for producing, storing, and utilising acetylene gas. Oct. 14.

1896.

1129. F. Knoefl. Method of producing light. Oct. 21.

5905. G. Webb and J. W. Kelly. Automatic gas generator. Sept. 23.

6919. J. E. Dowson. Apparatus for making combustible gas. Oct. 21.

8161. W. Tyree. Combustion of fuel. Sept. 23.

13,618. J. Musso. Portable and hygienic incandescent lighting wherein the evaporation of hydrocarbons is produced under pressure. Oct. 14.

14,278. F. P. J. Ackemaon. Apparatus for producing acetylene gas. Sept. 23.

15,500. R. J. Eiffe.—From F. Meyer and Co. Preparation of incandescence bodies. Sept. 30.

16,345. R. Haddad.—From A. Boter. Apparatus for production of acetylene gas. Sept. 23.

16,728. A. J. Boulton.—From F. Alexandre. Production of acetylene gas, and means or apparatus employed therein. Sept. 23.

17,450. W. C. Clarke. Apparatus for generating acetylene gas. Sept. 23.

17,729. I. N. Knapp. Treatment of illuminating gas. Oct. 7.

18,924. A. Spranger. Production or manufacture of ozone solutions. Oct. 7.

19,288. A. J. Boulton.—From H. E. Fuller. Construction of apparatus for generating gas by the chemical action of a liquid upon a solid material. Oct. 14.

20,599. J. A. Deuther. Improvements in and relating to method of and apparatus for producing acetylene gas. Oct. 21.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

20,676. O. N. Witt. Manufacture of derivatives of para-amido-alpha-naphthol and of colouring matters therefrom. Sept. 18.

21,196. G. B. Ellis.—From La Société Chimique des Usines du Rhone anciennement G. P. Monnet et Cartier. Improvements in and relating to the production of colouring matters. Sept. 24.

21,197. G. B. Ellis.—From La Société Chimique des Usines du Rhone anciennement G. P. Monnet et Cartier. Improvements in and relating to the production of colouring matters. Sept. 24.

21,198. G. B. Ellis.—From La Société Chimique des Usines du Rhone anciennement G. P. Monnet et Cartier. Improvements in and relating to the manufacture of colouring matters. Sept. 24.

21,211. W. Clark.—From C. H. Boehringer and Sohn. Process of preparing solutions of artificial and natural colouring matters for dyeing and printing purposes. Sept. 24.

21,431. R. Wilkinson and F. Wilkinson. A new or improved dye. Sept. 28.

21,437. C. D. Abel.—From The Actien Gesellschaft für Anilin Fabrikation. Manufacture of a new black mordant-dyeing colouring matter. Sept. 28.

21,493. I. Levinstein and Levinstein, Lim. Production of new direct colouring matters. Sept. 29.

21,498. L. P. Marchlewski, E. S. Wilson, and E. Stewart. Improvements in the production of dyes. Sept. 29.

22,041. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Manufacture of ortho- and para-nitrobenzyl-aniline and its homologues. Oct. 5.

22,420. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. The manufacture of chemical compounds and of dyestuffs derived therefrom. Oct. 9.

22,943. H. H. Lake.—From Farbwerk Muhlheim. Improvements in the manufacture of azo colouring matters. Oct. 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

22,481. O. Imray. — From The Farbwerke vormals Meister, Lucius, and Brüning. Manufacture of a compound of salicylic acid and hexamethylenetetramine. Oct. 7.

23,054. C. D. Abel. — From The Actien Gesellschaft für Anilin Fabrikation. Manufacture of derivatives of the triphenylmethane series. Oct. 7.

23,312. J. Imray. — From La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis. Manufacture of sulphuretted colouring matters dyeing non-mordanted fibres. Oct. 7.

23,853. O. Imray. — From The Farbwerke vormals Meister, Lucius, and Brüning. Manufacture of basic blue dyestuffs. Oct. 21.

1896.

1331. H. H. Lake. — From K. Ochler. Manufacture of colouring matters. Oct. 21.

V.—TEXTILES, COTTON, WOOL, SILK, ETC.

APPLICATIONS.

20,714. R. Thomas and E. Prevost. Improvements in or relating to mercerising vegetable fibrous substances. Complete Specification. Sept. 18.

20,736. C. O'Brien and J. Shearer. Method for improving the colour of raw jute fibre. Sept. 19.

20,737. C. O'Brien and J. Shearer. Method for improving the colour of raw jute fibre. Sept. 19.

20,360. C. Junge. — From S. B. Allison. Improvements in machines for separating and cleaning the fibres of plants of every description. Sept. 22.

21,370. A. Wyser. An improved process and apparatus for treating cotton yarns for the purpose of obtaining a glossy appearance of the yarn. Sept. 26.

21,557. R. B. Hardman. Improvements in apparatus for clearing fibres from grease and impurities. Sept. 29.

22,197. W. C. Kipling. Improvements in and relating to waterproofing silk, wool, or other fabrics. Oct. 6.

22,605. S. Whittaker. Improvements in or connected with machinery for preparing or spinning cotton or other fibrous materials. Oct. 12.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

20,846. B. Lec. Improvements in and connected with vessels for dyeing purposes. Sept. 21.

21,244. F. V. Williams. An improved process for the fixation of soluble colouring matters or mordants or pigments or powders upon woven fabrics. Sept. 25.

21,245. J. Arrowsmith and G. A. Kennedy. — From W. Coventry. Improvements in or applicable to apparatus for dyeing or bleaching yarn in cop or other compact form. Sept. 25.

21,286. J. O. O'Brien. — From G. Schneider. Improvements in or connected with the scouring or dyeing of wool and other fibres and textile fabrics. Sept. 25.

21,492. F. Davies and A. Liebmann. A new or improved machine for dyeing, finishing, sizing, washing, or similarly treating yarn. Sept. 29.

22,218. T. Ingham. Improved apparatus for dyeing mixed fabrics. Oct. 7.

22,522. A. M. Clark. — From C. H. Boehringer and Sohn. An improved mordanting agent and process for vegetable fibres. Oct. 10.

22,823. J. Kent. An improved method or process of bleaching cotton and other vegetable textile materials. Oct. 14.

22,931. W. Shedlock. Improvements relating to the bleaching, dyeing, and washing of textile materials and to apparatus therefor. Oct. 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

18,040. R. Thomas and E. Prevost. Improvements in or relating to Mercer's system of treating vegetable fibres or fabrics for dyeing purposes. Sept. 30.

21,355. L. C. G. Sharp. Production of coloured border effects on fast black dyed grounds upon ordinary grey cotton cloths, especially suitable for umbrella cloths, selvedges, and the like. Oct. 14.

21,393. M. Walton. Bleaching kiers. Sept. 23.

1896.

372. A. M. Clark. — From C. H. Boehringer. Process of mordanting vegetable textile materials for dyeing. Sept. 23.

4890. A. Ashworth. Fixing metallic mordants on fibres and fabrics. Oct. 14.

14,252. A. Eudler. Process for bleaching cotton and cotton goods. Oct. 14.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

20,290. J. Walter and C. Lehmann. Nitric acid regenerator. Complete Specification. Sept. 14.

20,423. P. Jensen. — From H. Cappelen and D. Cappelen. Improvements in pumping apparatus for chlorine gas and the like. Complete Specification. Sept. 15.

20,598. J. A. Deuther. Improvements in and relating to calcium carbide and the treatment of the same to form a uniform composition. Complete Specification. Sept. 17.

20,794. B. Kosmann. Method of manufacturing thorium hydrate. Sept. 19.

20,818. M. N. d'Andria. Improvements in and connected with the manufacture of magnesia and of calcium carbonate. Sept. 21.

20,822. M. N. d'Andria. Improvements in and connected with the utilisation of calcium chloride solutions, the recovery of hydrochloric acid, and the manufacture of magnesium sulphate or magnesia and chlorine. Sept. 21.

20,883. G. P. Lewis and R. A. Cripps. Improved means for manufacturing and recovering cyanides, and apparatus therefor. Sept. 21.

21,178. A. Schmitz and E. C. W. Toenges. Process for obtaining tartaric acid and tartrates. Sept. 24.

21,205. Brante, Etienne, and Co. Improved apparatus for the manufacture of sulphuric acid. Sept. 24.

21,443. G. Webb, jun., and J. W. Kelly. Improved apparatus for the production of carbide of calcium. Sept. 28.

21,572. M. P. E. Letang. An improved process for the treatment of carbide of calcium. Complete Specification. Sept. 29.

21,764. C. C. Moore. Improvements in the treatment of crude borates and in obtaining boric acid. Oct. 1.

21,892. J. J. Holleyhead. Improved apparatus for the manufacture of salt. Oct. 2.

21,953. T. Savage. Improvements in the production of or copper sulphate. Oct. 3.

22,512. M. Schwab. Improved method of and apparatus for concentrating sulphuric acid. Oct. 10.

22,717. G. Kynoch and Co., Lim., and A. T. Cocking. An improved method and apparatus for mixing and conveying acids for use in nitro-glycerine and other manufactures. Oct. 13.

22,718. G. Kynoch and Co., Lim., and A. T. Cocking. An improved process for denitrating acid which has been used in the nitro-glycerine manufacture. Oct. 13.

22,792. J. W. Chenhall. Improvements in the manufacture of bleaching compounds. Oct. 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

18,785. H. Hibbert and A. Frank. Production of phosphors, its acids and salts, from mineral phosphates, bones, and other materials containing phosphoric acid. Oct. 14.

19,201. G. C. Downing.—From J. R. Moise. Manufacture of alkaline cyanides, ferrocyanides, and their derivatives, and apparatus therefor. Oct. 14.

20,377. W. Mills. Manufacturing metallic fluorides. Sept. 9.

21,380. C. F. Claus. Roasting sulphide ores. Sept. 23.

21,678. J. Raschen and J. Brock. Manufacture of cyanides and ferrocyanides from sulphocyanides and the recovery of by-products. Sept. 23.

21,997. T. L. Willson. Production of metallic cyanides and other nitrogen compounds. Oct. 7.

22,037. D. A. Peniakoff. Manufacture or production of alkaline silicates or silicates of the alkaline earths, and of chlorine or hydrochloric acid. Oct. 23.

22,038. D. A. Peniakoff. Manufacture or production of alkaline aluminates of the alkaline earths, and of sulphurous acid. Sept. 23.

22,039. D. A. Peniakoff. Manufacture or production of aluminates and of sulphurous acid, and of chlorine or hydrochloric acid as by-products. Sept. 23.

23,572. W. P. Thompson.—From The Chemische-Werke vormals H. and E. Albert. Manufacture of alkaline phosphates and caustic alkali. Oct. 21.

1896.

720. B. Willecox.—From The Chemische Fabrik Griesheim. A process for obtaining hydrosulphide of sodium or sulphate of sodium and sulphuretted hydrogen and sulphate of calcium from sulphide of calcium or soda residues and mono- or bi-sodium sulphate. Oct. 14.

VIII.—GLASS, POTTERY, AND ENAMELS.

APPLICATIONS.

20,439. J. T. Newell. Improved method of preparing granulated glass for tiles, facing bricks, walls, panels, and the like. Sept. 15.

20,975. C. Mountford. Improvements in the decoration of pottery, porcelain, earthenware, glass, and the like. Sept. 22.

21,194. A. Simmons and G. M. Fricake. Improvements in ornamenting or decorating glass, earthenware, metal, and other plates and sheets, and other surfaces. Sept. 24.

21,762. D. Laffan, G. Moore, and T. J. Glynn. Improvements in or relating to apparatus for blowing or forming bottles and other glassware. Complete Specification. Oct. 1.

22,486. W. F. Mason. Improvements in kilns for bricks, pottery, and the like. Oct. 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

24,858. J. Maddock. A kiln hood for placing pottery-ware during fire. Sept. 30.

1896.

17,390. P. T. Sievert. Process and apparatus for the manufacture of glass sheets, glass tubes, and cylinders for the production of glass sheets and other articles. Sept. 30.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

20,432. J. Grunhut. Improvements in the manufacture of artificial stone. Complete Specification. Sept. 15.

20,603. G. G. M. Hardingham.—From F. D. Cumber. Improved means applicable for use in drying cement, slurry, liquid clay, and other substances in like condition. Sept. 17.

20,612. P. Kleber. A new or improved manufacture of artificial stone. Complete Specification. Sept. 17.

20,693. C. O. Trechmann. Improvements in the manufacture of cements, whitening, and the like, and in apparatus adapted for use in connection therewith. Sept. 18.

21,313. G. C. Levey and C. L. O'Brien. Improvements in the manufacture of artificial stone. Sept. 25.

21,781. A. C. Ponton. Improvements in the manufacture of fire-bricks and fireproof mortar. Oct. 2.

23,105. J. A. Just. Improvements in the manufacture of compositions for paving and like purposes. Complete Specification. Oct. 17.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

18,331. E. Robbins. An improved cement and means and method for producing the same, and architectural and other works thereof. Oct. 7.

18,410. H. Hellewell. Preparation or manufacture of asphalt or cement for laying pavements, floors, or the like. Sept. 30.

19,101. A. Gosling. Artificial stone. Oct. 7.

21,735. A. B. Grieg. Construction of paving blocks for roads, footpaths, and other ways. Oct. 21.

21,870. F. Hinton and J. Day. Fireproof floors. Oct. 21.

1896.

8311. L. Preussner. Production of artificial stone. Oct. 21.

11,738. H. H. Lake.—From M. Friedheim. Plastic substances for building and decorative purposes. Oct. 21.

15,520. K. Hergenbalm. Process for the preparation of masonry (in marble, granite, syenite, sandstone, and the like) for pillars, pedestals, door and window cases, monuments, and the like, or other objects. Oct. 14.

16,258. A. Gibbs and Eastwood and Co. Burning bricks and other material, and apparatus therefor. Oct. 7.

17,799. E. T. Dumble. See Class XIII.

X.—METALLURGY, MINING, ETC.

APPLICATIONS.

14,330A. A. G. Brown. Improvements in the manufacture of rods and tubes mainly from aluminium and aluminium alloys. Complete Specification. Filed Oct. 17, date claimed June 29, 1896.

20,504. A. J. Boulton.—From H. L. Salman. Improvements in or relating to the recovery of precious metals from their solutions. Sept. 16.

20,510. J. Kidd. Improvements in connection with blast furnaces and the like. Sept. 16.

20,615. A. J. Boulton.—From Kochler and Co. Improvements in or relating to the obtainment of metals or metallic compounds from ore residues or other bodies containing them. Sept. 17.

20,679. H. Facer. Improvements in soldering aluminium. Sept. 18.

20,838. W. Noad and R. J. Lightfoot. Improved method for the extraction of and recovery of metallic copper. Sept. 21.

20,866. B. K. Jamison. Improvements in the treatment of crude or low-grade steel. Sept. 21.

21,012. A. J. C. Nettel. A new or improved process for the extraction of silver from refractory sulphide ores and apparatus connected therewith. Sept. 22.

21,038. W. Douglas. Improvements in the recovery of gold and silver and other metals from cyanide solution. Sept. 23.

21,394. J. W. Chenhall. Improvements in the treatment of arsenical and iron sulphide ores containing gold. Sept. 28.

21,428. J. Pullman. Improvements in the treatment of sulphide ores. Sept. 28.

21,827. S. Curteis. Improvements in the extraction of gold from ores or other substances containing same. Oct. 2.

21,976. A. L. Le Redotte. Improvements in processes for the manufacture of certain metals and alloys, especially for the manufacture of magnesium and its alloys. Oct. 3.

22,355. W. P. Thompson.—From A. Sinding-Larsen. Improved process for extracting metals. Complete Specification. Oct. 8.

22,361. J. Armstrong. Improvements in the extraction of lead, zinc, gold, silver, and other metals from sulphides, refractory or other ores or mattes. Oct. 9.

22,715. J. W. Clarke. Improvements in and connected with amalgamating apparatus for extracting gold and silver from their ores. Complete Specification. Oct. 13.

22,721. T. Storer. Improvements in the treatment of nickel ores for extraction of the nickel and the production of iron oxide pigment. Oct. 13.

22,791. T. Teague. Bar tin or metal casting machine. Oct. 14.

22,923. W. Beardmore and H. V. Holden. Improvements in casting armour plates, and moulds therefor. Oct. 15.

22,976. D. C. Dalzell and A. Fairley. Improvements relating to the annealing of steel or iron. Oct. 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

15,356. J. W. Butler. Apparatus for extracting gold by means of mercury. Sept. 23.

16,303. J. Cobeldiek. Treatment of slimes or tailings for the extraction of gold or silver therefrom by means of solvents, and apparatus therefor. Oct. 7.

17,250. R. I. Roman. Aluminium compounds, and means for producing same. Sept. 23.

18,116. F. C. May. Process for the extraction of gold and silver from their ores. Sept. 30.

22,041. F. A. Ellis. Soldering or brazing metals, particularly applicable to aluminium alloys. Sept. 23.

22,732. C. A. Burghardt and G. Rigg. Process and apparatus for the electrolytic production of metallic zinc from ores of zinc, and metallic zinc and metallic copper from zinc ores containing copper, and the production of oxygen gas in the cases specified. Oct. 14.

22,812. H. S. Maxim. Extracting gold from refractory auriferous ores. Oct. 21.

1896.

9388. C. A. Burghardt and G. Rigg. Obtaining copper from copper ores. Oct. 21.

13,163. C. C. Schirm and A. Silbermann. Producing an even silver ground for underlying enamel. Sept. 30.

17,076. L. Albrecht. Tin-plate furnaces. Sept. 23.

18,081. C. P. Sherk, J. L. Rutter, and S. Weiss. Process and means for converting pig iron into malleable iron or steel. Sept. 23.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

20,505. H. Imray.—From R. J. W. Grindle. An improvement in electrodes for secondary voltaic batteries. Complete Specification. Sept. 16.

20,600. J. A. Deuther. Improvements in and relating to electrodes. Complete Specification. Sept. 17.

20,601. J. A. Deuther. Improvements in and relating to electric furnaces. Complete Specification. Sept. 17.

20,707. J. Greenwood. Improvements in coating tubes by electro-deposition. Sept. 18.

21,027. W. L. Wise.—From The Aluminium Industrie Aktien Gesellschaft. Improvements in electrolytic apparatus. Sept. 22.

21,273. J. E. Liardet. Improvements in or relating to electric storage batteries. Sept. 25.

21,509. J. G. A. Rhodin. An improved electrolyser or electrolytic apparatus. Sept. 29.

21,749. The Sussmann Electric Miners' Lamp Co., Ltd., and S. A. Rosenthal. Improvements in active material for secondary battery plates. Oct. 1.

21,826. T. Froggatt. Improved grids for plates in secondary electrical batteries. Oct. 2.

22,069. D. Young.—From La Société Anonyme "Accumulateur Éclair." Improvements in electric accumulators or storage batteries. Oct. 5.

22,129. H. Maxim. Improvements in methods or processes for electro-thermally treating materials for the manufacture of calcium carbide and the reduction of metals from their oxides or other compounds. Oct. 6.

22,423. L. Epstein. An improved manufacture of electrodes for secondary voltaic batteries. Oct. 9.

22,595. A. G. New. Improvements in electric accumulators. Oct. 12.

23,040. A. G. Adamson. Improvements in the construction of electrical accumulators and primary cells. Oct. 17.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

17,745. H. H. Lake.—From C. Hoepfner. Electrolytic cells. Sept. 30.

19,669. A. Schanschick. Secondary battery plates. Sept. 23.

19,934. C. A. Burghardt and G. Rigg. Process and apparatus for the electrolytic production of metallic zinc and metallic copper from zinc ore containing copper, and oxygen gas as a by-product. Sept. 30.

20,828. W. Rowbotham. Primary electric batteries. Sept. 23.

20,843. C. P. Shrewsbury, F. L. Marshall, and J. L. Dobell. Electric batteries. Sept. 30.

22,207. C. Kellner. Electrodes suitable for electrolytic apparatus. Sept. 30.

1896.

17,549. J. B. Whittemore. Electrical primary battery. Oct. 21.

18,628. J. F. Baehmann, A. Vogt, C. C. Weiner, J. Kirchner, and A. König. Incandescence body for electric glow-lamps, and process of manufacture of the said body. Oct. 7.

XII.—FATS, OILS, AND SOAP.

APPLICATIONS.

20,438. T. Coad. Improved means and apparatus for treating fat. Sept. 15.

20,755. C. Bilton. Improved lubricating composition for machinery bearings and the like. Sept. 19.

21,048. E. S. Wilson and E. Stewart. Improvements in the manufacture of soap. Sept. 23.

21,604. J. W. Hope. Improvements in or connected with the treatment of the residue or by-products resulting from the purification of cotton-seed and other vegetable or analogous animal oils, and the manufacture or recovery therefrom of certain valuable products or substances. Sept. 30.

21,999. J. W. Hope. Improvements in or connected with the refining of cotton and other seed or vegetable oils. Oct. 5.

22,390. J. Symons. An improved soap. Oct. 9.

22,424. A. G. Petty. Apparatus for purifying oils and fats. Oct. 9.

22,873. J. G. Hargrave and A. Hargrave. Improvements in processes for purifying and deodorising butter and other solid fats and oils. Complete Specification. Oct. 15.

22,981. T. H. Lawson and A. J. Lawson. Improvements in machinery or apparatus for cutting blocks of soap into slabs and bars. Oct. 16.

22,982. T. H. Lawson and A. J. Lawson. Improvements in and relating to vehicles for the transport of soap and soap frames in soap factories. Oct. 16.

23,025. F. W. Wright and The United Alkali Co., Ltd. Improvements in the manufacture and production of "dry soap" or soap-powder. Oct. 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

18,760. S. E. von Graeve. New or improved process of manufacture of petroleum soap. Sept. 30.

21,557. P. C. D. Castle. New or improved detergent or tanning substance. Sept. 23.

22,332. J. B. McArthur. Liquid disinfectant soap. Sept. 30.

1896.

16,746. W. F. Haywood. Process and apparatus to be used in the manufacture of soap. Sept. 23.

16,766. J. Merz. Extraction of fats, oils, resins, sulphur colours, tanning materials, and the like by means of volatile solvents, and apparatus therefor. Oct. 7.

XIII.—PAINTS, PIGMENTS, VARNISHES, RESINS, INDIA-RUBBER, Etc.

APPLICATIONS.

20,295. H. Williamson. Improved means for mixing or blending pigments to obtain pigments of desired colour. Sept. 14.

20,753. H. Millington and T. H. Parry. An improvement in the treatment of india-rubber. Sept. 19.

20,932. P. Fenton. Improvements in the manufacture of artificial gutta-percha and caoutchouc-like substances. Sept. 22.

21,138. C. Thomas. An improved protective composition for application to galvanised and other iron, steel, and other metals as a foundation for painting, and to prevent rust. Sept. 24.

22,344. J. Jones. Improved manufacture of paint or similar composition. Oct. 8.

22,721. T. Storer. See Class X.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

19,130. P. C. D. Castle. New or improved chemical substance and the application thereof to industrial purposes, such as rubber, gutta-percha, or celluloid substitutes, insulations of electrical conductors, coverings for ships' bottoms, or wall or floor coverings. Oct. 14.

21,226. D. Z. Woods and W. P. Mackay. Improved composition for blacking and dressing leather. Oct. 7.

23,155. A. T. Hall. Preparation of colour wash or distemper paints. Oct. 7.

1896.

14,983. A. B. Browne. Manufacture of white lead. Oct. 21.

17,799. E. T. Dumble. Process for hardening bituminous substances. Oct. 7.

19,318. G. W. N. Hamilton. An enamel paint and combination of materials for composing same. Oct. 14.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATIONS.

20,420. W. Dennison. Improvements in connection with the manufacture of leather. Sept. 15.

21,210. W. Clark.—From C. H. Boehringer and Sohn. Improvements in tanning hides and skins. Sept. 24.

21,774. H. Gardner.—From C. W. Luther. Improved manufacture of waterproof glue. Oct. 1.

22,103. J. Forster. Improvements in the method of and means for tanning hides and the like. Oct. 6.

22,965. F. Billing and A. Letalle. A new material to be employed as a substitute for leather, paper, and other analogous substances, and a process of manufacturing the same. Oct. 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

18,879. L. A. Groth. Apparatus employed in tanning hides and skins. Oct. 7.

21,557. P. C. D. Castle. See Class XII.

21,720. C. D. Abel.—From The Chemische Technisches und Hygienisches Institut Dr. Popp and Dr. Becker. Improvements in lyes or liquors for preparing hides for tanning. Oct. 14.

23,310. A. Brogard. Process for the removal of lime from hides and skins after treatment in the lime bath. Oct. 7.

1896.

2993. A. Zendroni. A new adhesive and agglutinating substance. Oct. 7.

16,609. E. Avellis and E. Koster. Process for preparing chrome-dressed leather for dyeing purposes. Sept. 23.

20,154. R. W. James.—From S. Alimonda. Process for tanning hides. Oct. 21.

XV.—AGRICULTURE AND MANURES, Etc.

APPLICATIONS.

20,509. A. Schlepitzky. A new or improved artificial manure or fertiliser. Complete Specification. Sept. 16.

22,666. C. H. Langdale and A. W. Langdale. Improvements in the treatment of ground slags intended for use as fertilisers. Complete Specification. Oct. 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

18,635. T. Jamieson. Process for the manufacture of phosphates of ammonia and potash in an alkaline mixture suitable for manure. Sept. 30.

1896.

6405. N. F. B. de Merecy. Manufacture of manure. Oct. 21.

XVI.—SUGARS, STARCHES, GUMS, Etc.

APPLICATIONS.

20,434. L. F. Haubman. Improvements in apparatus for clarifying saccharine solutions. Sept. 15.

20,771. H. Helbing. Improvements in the manufacture of saccharine compounds. Sept. 19.

22,018. J. Cleave. An improved steam sugar boiler. Complete Specification. Oct. 5.

COMPLETE SPECIFICATION ACCEPTED.

1896.

18,138. C. F. Kastengren. Method of purifying molasses, syrup, or other solution of sugar by means of animal charcoal. Sept. 30.

XVII.—BREWING, WINES, SPIRITS, ETC.**APPLICATIONS.**

20,521. A. L. Burlin. Improvements in the manufacture of yeast. Sept. 16.

21,011. G. E. Jacquemin. A new or improved method of and apparatus for the manufacture of pure yeasts. Sept. 22.

21,022. A. E. Feroe. Improvements in a process and apparatus for treating malt liquors. Complete Specification. Sept. 22.

21,118. J. Kwiatkowski. New or improved process for adding iron to beer. Complete Specification. Sept. 23.

22,403. C. H. McEuen.—From J. T. Bennett. Apparatus and process for removing saccharine and other impurities from wine and spirits. Complete Specification. Oct. 9.

23,026. E. W. Walker. Improvements in the treatment or preparation of malt for brewing or other purposes. Oct. 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

17,611. J. Bradbury. Methods of utilising the waste products from breweries, distilleries, vineyards, and the like, including suitable machinery and apparatus for the same. Sept. 30.

18,296. J. W. Folkerts. Manufacture of yeast. Sept. 23.

20,130. R. Free. Preparation or treatment of beer. Sept. 30.

22,035. J. B. Grisez. A process for the aëration, oxidation, and oxygenation of wort. Oct. 7.

1896.

17,246. L. Prochazka. Process and apparatus for mashing and brewing. Oct. 21.

XVIII.—FOODS, SANITATION, ETC., AND DISINFECTANTS.**APPLICATIONS.****A.—Foods.**

22,696. T. O. Kent. A new or improved extract of coffee and the method of preparing the same. Oct. 13.

B.—Sanitation.

20,733. J. B. Petrie. A method or process and apparatus for the clarification and purification of liquid sewage or other foul waters. Sept. 19.

22,768. C. Fell. An improved filter for sewage effluent and the like. Oct. 14.

23,042. D. Cameron, F. J. Commin, and A. J. Martin. Improvements in apparatus for the treatment of sewage or other liquids. Oct. 17.

C.—Disinfectants.

20,792. W. O. Quibell, T. O. Quibell, O. Quibell, and W. B. B. Quibell. Improvements in sheep-dip powder. Complete Specification. Sept. 19.

COMPLETE SPECIFICATIONS ACCEPTED.**B.—Sanitation.**

1895.

17,828. C. Tellier. Manufacture of ice and the production of cold, and apparatus therefor. Sept. 30.

19,952. C. MacDonald. Manufacture of material for filtering water, sewage effluents, saccharine juices, alcoholic liquors, illuminating gas, and other liquids and fluids, and for use in the manufacture of steel. Oct. 21.

21,856. G. Watson. Furnaces for the destruction of town refuse. Sept. 23.

23,064. J. Hargreaves. Treatment of sewage and the obtention of valuable products. Oct. 21.

C.—Disinfectants.

1895.

20,355. G. C. Kinloch, C. Heap, and J. H. Butterworth. Production of compositions for treating sewage matters or other foul waters. Oct. 21.

22,332. J. B. McArthur. Liquid disinfectant soap. Sept. 30.

22,364. C. C. Whitaker. Manufacture of disinfectants and antiseptic compounds. Oct. 7.

1896.

1409. A. J. Boulton.—From F. Fritzsche and Co. Manufacture of an antiseptic disinfectant. Oct. 14.

XIX.—PAPER, PASTEBOARD, ETC.**APPLICATIONS.**

21,978. A. Masson. An improved method and means of drying and treating coated paper. Oct. 5.

22,848. R. A. McLaurin and Smith, and McLaurin. Improvements in the manufacture of paper. Oct. 15.

22,965. F. Billing and A. Letalle. See Class XIV.

23,094. C. E. Challis. Waterproof cellulose. Oct. 17.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

21,470. E. Margu. Cellulose compounds and articles manufactured therefrom. Sept. 30.

22,030. H. W. Reynolds. A new or improved material to be used in substitution of whalebone or horn, and process and apparatus for producing the same. Sept. 30.

1896.

13,242. W. Hankemoller. Process for manufacturing artificial whalebone. Sept. 23.

18,265. M. Honig. Manufacture of tannin extract from sulphite cellulose lyes. Oct. 7.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.**APPLICATIONS.**

20,622. G. B. Ellis.—From La Société Chimique des Usines du Rhone, anciennement G. P. Monnet et Cartier. Improved means of distributing formic aldehyde vapours. Sept. 17.

20,697. A. Zimmermann.—From The Chemische Fabrik auf Actien vormals E. Schering. The production of a vinylacetonealkamine and of anaesthetics therefrom. Sept. 18.

20,773. J. J. A. Trillat. Improvements in the production of vapours of formic aldehyde, and apparatus for the same. Filed Sept. 19. Date applied for Feb. 25, 1896, being date of application in France.

21,026. W. L. Wise.—From The Chemische Fabrik von Heyden Gesellschaft mit beschränkter Haftung. Improvements in the manufacture of saccharine. Complete Specification. Sept. 22.

21,031. J. G. McIntosh. Improvements in the manufacture and application of terebenthene mono hydrochloride. Sept. 22.

21,106. G. B. Ellis.—From La Société Chimique des Usines du Rhone anciennement G. P. Monnet et Cartier. Improvements in the manufacture of vanillin. Sept. 23.

22,139. M. Dinesman. Process for the manufacture of substitutes for natural musk. Complete Specification. Oct. 6.

22,351. J. Y. Johnson.—From R. Koeppe and Co. Improvements in the manufacture or preparation of lactic acid. Oct. 8.

22,696. T. O. Kent. *See* Class XVIII. A.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

21,203. A. Eichengrün. New and useful bodies derived from iodoform. Sept. 30.

22,251. B. Zahorski, F. Hunter, and J. Brock. Improvements in the treatment of impure bisulph for refining the same. Sept. 30.

1896.

17,401. C. Fahlberg. Manufacture of saccharine or compounds thereof, or mixtures containing the same, and in the production and treatment of materials for use therein. Oct. 21.

XXI.—PHOTOGRAPHY.

APPLICATIONS.

20,307. M. Sappey. New or improved apparatus or means by which successive photographs can be produced. Sept. 14.

20,387. T. C. Marecau. Producing photographs in relief. Complete Specification. Sept. 15.

20,831. A. P. Okell. Improvements in apparatus for use in the development and treatment of flexible photographic films or tissues. Sept. 21.

21,495. W. S. Wain. Improvements in dishes or baths employed in developing and like photographic and chemical operations. Sept. 29.

22,680. W. Friese-Greene and J. Collings. Improvements in the production of coloured prints. Oct. 13.

22,689. W. Friese-Greene and J. A. Prestwich. Improved means for making and projecting kinetoscopic films. Oct. 13.

COMPLETE SPECIFICATION ACCEPTED.

1895.

22,757. A. Musker. Drying photographic negatives and the like. Oct. 7.

XXII.—EXPLOSIVES, MATCHES, Etc.

APPLICATIONS.

20,537. A. G. Manifold. Improved matches, and cases for use in connection therewith. Sept. 17.

20,641. W. Norris. An improvement in the construction of blasting or other explosive cartridges or cartridge cases, thereby enabling explosions to which water is detrimental to be fired or exploded under or in water. Sept. 18.

20,675. M. Bielefeldt. Blasting cartridge. Sept. 18.

22,120. F. A. Halsey and W. C. Savage. Smokeless gunpowder. Complete Specification. Oct. 6.

22,162. J. C. Hamilton. Improvements in explosive compounds for blasting purposes. Oct. 6.

22,190. G. Kynoch and Co., Lim., and A. T. Cocking. Improvements relating to the manufacture of explosives. Oct. 6.

22,540. R. W. Streblener. A new or improved solvent or solvents for nitrocellulose, whereby improved solutions are obtained. Oct. 10.

22,717. G. Kynoch and Co., Lim., and A. T. Cocking. *See* Class VII.

22,718. G. Kynoch and Co., Lim., and A. T. Cocking. *See* Class VII.

COMPLETE SPECIFICATIONS ACCEPTED.

1895.

21,755. T. B. Wilson. Production of nitrogen compounds and apparatus therefor. Sept. 23.

21,995. W. F. Reid and E. J. V. Earle. Nitro-compounds. Oct. 14.

1896.

17,204. M. Bielefeldt. Process for the manufacture of explosives containing saltpetre. Oct. 14.

18,078. B. Wilcox.—From The Actien Gesellschaft Dynamit Nobel. An improved explosive or blasting composition. Sept. 23.

THE JOURNAL OF THE Society of Chemical Industry: A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 11.—Vol. XV.]

NOVEMBER 30, 1896.

[Non-Members 30/- per annum; Members
21/- per Set of extra or back numbers;
Single Copies (Members only) 2/6.]

The Society of Chemical Industry.

Past Presidents:

Sir H. E. Roscoe, LL.D., V.P.R.S.	1881—1883.
Sir Frederick Abel, Bart., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
Dr. W. H. Perkin, F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Prof. James Dewar, F.R.S.	1887—1888.
Ludwig Mond, F.R.S.	1888—1889.
Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
B. Rider Cook	1890—1891.
Prof. J. Emerson Reynolds, M.D., D.Sc., F.R.S.	1891—1892.
Sir John Evans, K.C.B., F.R.S.	1892—1893.
E. C. C. Stanford	1893—1894.
Dr. T. E. Thorpe, LL.D., F.R.S.	1894—1895.
Thomas Tyrer	1895—1896.

COUNCIL FOR YEAR ENDING JULY, 1897.

President: Dr. Edward Schunck, F.R.S.

Vice-Presidents:

Chas. Dreyfus.	E. C. C. Stanford.
Dr. A. Dupré, F.R.S.	G. N. Stoker.
Prof. A. K. Huntington.	Dr. T. E. Thorpe, F.R.S.
Boverton Redwood.	Prof. W. A. Tilden, F.R.S.
Sir H. E. Roscoe, F.R.S.	Thomas Tyrer.
A. Gordon Salamon.	

Ordinary Members of Council:

George Beilby.	C. C. Hutchinson.
R. Forbes Carpenter.	Ivan Levinstein.
R. Le Neve Foster.	J. S. McArthur.
Oscar Guttman.	B. E. R. Newlands.
Douglas Herman.	Sir Robert Pullar.
David Howard.	Wm. Thorp, B.Sc.

With the Chairmen and Secretaries of Sections.

Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

Honorary Foreign Secretary:

Ludwig Mond, F.R.S.

General Secretary: Charles G. Cresswell.

Offices: Palace Chambers, 9, Bridge Street, Westminster, S.W.

THE JOURNAL.

Publication Committee:

The President.

A. H. Allen.	C. Clarke Hutchinson.
G. H. Bailey, D.Sc., Ph.D.	Wm. Kellner, Ph.D.
Joseph Bernays, M.I.C.B.	J. Lewkowsitch, Ph.D.
H. Brunner.	A. R. Ling.
A. C. Claudet.	Ludwig Mond, F.R.S.
E. Rider Cook.	B. E. R. Newlands.
Chas. Dreyfus.	John Pattinson.
Sir John Evans, K.C.B., F.R.S.	W. H. Perkin, Ph.D., F.R.S.
G. G. Henderson, D.Sc.	H. R. Procter.
John Heron.	Boverton Redwood.
D. B. Hewitt, M.D.	Walter F. Reid.
David Howard.	John Spiller.
Prof. J. J. Hummel.	William Thorp.
Prof. A. K. Huntington.	Thomas Tyrer.
F. Hurter, Ph.D.	Lewis T. Wright.

Editor:

Watson Smith, 34, Upper Park Road, Haverstock Hill, N.W.

NOTICES.

COLLECTIVE INDEX.

A collective index, embracing the whole Journal from the Proceedings of the First Annual General Meeting, 1881, to the close of 1895, is now in preparation, and will be ready about the end of the current year. It will contain both a subject-matter and authors' names portion and will be a volume of about 500 pages, uniform in size with the Journal.

The prices will be as follows:—

To Members (see Rules 25 and 27) and Past Members (see Rule 30); Libraries, Corporations, and Exchanges on the Society's List.	Each copy 10s.
To Subscribers	12s. 6d.
To others.....	15s.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. **EXRE and SPORTISWOODE**, the Society's printers and publishers, to whom all communications respecting them should be addressed. The circulation of the Journal is now more than 3,000 per month.

Foreign and Colonial Members are reminded that the subscription of 25s. for 1897, payable on January 1st next, should be sent in good time to the Treasurer, in order to ensure continuity in the receipt of the Society's Journal. Any changes of address to appear in the new List of Members now in course of preparation, should reach the General Secretary not later than January 15th, 1897.

LIST OF MEMBERS ELECTED 22nd NOVEMBER 1896.

- Cairn, F. Ivan, 246, Park Avenue, Bridgeport, Conn., U.S.A., Metallurgist.
- Drewsen, Viggo B., Fort Edward, N.Y., U.S.A., Wood Pulp and Paper Expert.
- Ehrhardt, Ernest F., Badische Anilin Fabrik, Ludwigshafen am Rhein, Germany, Research Chemist.
- Fleisher, Saml. F., 25th and Hamilton Streets, Philadelphia, Pa., U.S.A., Woollen Manufacturer.
- Genth, Fred A., jr., 103, North Front Street, Philadelphia, Pa., U.S.A., Chemist.
- Grosvenor, Wm. M. jr., P.O. Box 183, Englewood, N.J., U.S.A., Technical Chemist.
- Haigh, Dr. Lagnel, Bayonne City, N.J., U.S.A., Chemist.
- Hyndman, Hugh H. F., 37, Great James Street, Bloomsbury, W.C., Analytical and Consulting Chemist.
